CLEMMYS INSCULPTA (Wood Turtle). **ECTOPARASITES.** Parasitic interactions between *Clemmys insculpta* and the turtle leeches *Placobdella parasitica* and *P. ornata* have been previously documented (Brewster and Brewster 1986. Herpetol. Rev. 17:48; Farrell and Graham 1991. J. Herpetol. 25:1–9; Hulse and Routman 1982. Herpetol. Rev. 13:116–117; Koffler et al. 1978. J. Herpetol. 12:571–572; Siddall and Desser 1992. Can. J. Zool. 70:123–128). We report additional instances of parasitism by *Placobdella parasitica* and *Placobdella ornata* on *Clemmys insculpta*.

On 3 June 1994 an adult female wood turtle (CL = 203.55 mm, CW = 146.05 mm, PL = 193.40 mm, mass = 1050 g) was captured in Pontiac County, Québec, Canada. Although completely healed, both of the turtle's front feet had been amputated and the anterior left side of the carapace had been mutilated. This turtle was parasitized by 4 or 5 brood size *Placobdella parasitica* on the integument adjacent to the femoral scute, in the right posterior limb socket. On 8 June 1994 the gravid turtle was recaptured

and 10 *Placobdella parasitica* (ROMIZ I 3277) were collected. Of those, two *P. parasitica* were found on the integument anterior to the left posterior limb. The remaining eight leeches consisted of a single brood located below the neck, immediately posterior to the gular scutes. On 15 June 1994 the turtle was once again recaptured on land. One *P. ornata* (ROMIZ I 3281) was found on the left posterior limb of the turtle.

On 9 June 1994 an adult female *C. insculpta* (CL = 196.15 mm, CW = 140.40 mm, PL = 192.35 mm, mass = 1000 g) was captured as it basked. A thorough examination of the turtle yielded two *P. ornata* (ROMIZ I 3288) in the left posterior axial area. One leech was firmly attached to the integument anterior to the limb, while the other was affixed to the foot.

On 22 June 1994 a gravid female wood turtle (CL = 198.05 mm, CW = 137.9 mm, PL = 190.90 mm, mass = 925 g) was caught while leaving a nesting site. A *P. ornata* was found on the fifth marginal scute, to the right of the nuchal.

Seventeen adult and one juvenile *C. insculpta* were captured as they basked on 2–4 May 1995, shortly after emergence from hibernation in Sutton County, Québec, Canada. Adult and juvenile *P. ornata* parasitized 22% (4/17) of the turtles. However, broods of *P. parasitica* were found on 50% (9/17). In all, 55% (10/17) of the wood turtles were parasitized by at least one of the leech species. Parasites were encountered almost exclusively in the posterior axial area, with 94% found on the posterior limbs, limb sockets, or tail. The exception was a brood of *P. parasitica* located below the neck and posterior to where the left gular scute joins with the integument. The turtle host had its left limb amputated, as was the case with the turtle from Pontiac County with a brood in the gular region. Measurements for adult turtles (N = 16) are given as mean ± SD (range) and were as follows: CL = 189.67 ± 10.02 mm (171.55–204.85 mm), CW = 140.09 ± 7.18 mm (126.85–151.50 mm), PL = 174.31 ± 6.71 mm (158.90–183.75 mm), mass = 970.62 ± 131.20 g (700–1200 g).

We thank Isabelle Bellavance, Chris Sharp, and Catherine Saumure for their assistance in the field, and Don Stacey of the Invertebrate Zoology Department of the Royal Ontario Museum. Research on the ecology of *Clemmys insculpta* was supported by the Québec Ministère de l'Environment et de la Faune, the St. Lawrence Valley Natural History Society, and the Biodôme de Montréal.

CLEMMYS MARMORATA (Western Pond Turtle). **TERRESTRIAL HABITAT USE.** The western pond turtle (*Clemmys marmorata*) is a highly aquatic species. It is known to utilize terrestrial habitats for dispersal, egg-laying, and/or overwintering (Holland and Bury, *in press*. *In* Pritchard and Rhodin (eds.), Conservation Biology of Freshwater Turtles Vol. 2, Chelonian Research Monographs). Here we report on a highly atypical instance of terrestrial habitat use by this species.

On 26 September 1993 at a second-order drainage in interior San Luis Obispo County, California, USA, we located 19 *C. marmorata* in a crevice in a granitic rock face immediately adjacent to a small (<40 m^2) pool (Fig. 1). The crevice was 95 cm long, 81–92 cm deep, angled at ca. 30° from the lowest to highest part, 20° from front to back, and oriented approximately W/SW. The lowest part of the crevice was ca. 15.3 cm above the surface of the pool. Eighteen animals (six males, four females, eight juveniles) were removed, weighed, measured, marked, and returned to the crevice. Mean carapace length (CL) was 99.7 mm (range 81.3–131.4), which was not significantly different (T-test, p = 0.21) from an additional 15 animals collected in this drainage on the same day (mean CL = 108.9 mm, range 54.4–140.7). Animals collected from the crevice were torpid, and all but two had their eyes closed and limbs retracted when first discovered.

On 18 September 1994, we returned to the site and discovered two juvenile turtles in the same crevice. These animals were 70.7 and 85.7 mm CL, and neither had been previously captured. The water level was 35.9 cm below the lowest portion of the crevice. On 9 September 1995 the crevice was checked and no turtles were observed. The site was revisited on 1 October 1995 and again no turtles were observed.

Western pond turtles typically seek refuge from predators by hiding in the most inaccessible microsites in the aquatic habitat. These include areas under rocks, logs, submerged and emergent vegetation, in undercut banks and occasionally in the substrate. Between 1980 and 1995 the senior author has collected by hand, marked, and released > 7000 individual *C. marmorata*. In less than 10 instances (0.14%) turtles were found above the standing water line, and in all cases they were within 20–25 cm horizontal distance and 5 cm vertical distance of the water's edge. The situation described above is unusual in that not only were turtles aggregated, but that they were well removed from the water both in elevation and distance.

The crevice may have provided both a thermal and predation refugium. Turtles in this drainage have been observed moving to and from the water in early fall, presumably responding to decreasing pool size and possible changes in prey abundance. Orientation of the crevice was such that during the late summer months only late afternoon sun would impinge on the opening, and would not penetrate any distance back into the rock. Thus, turtles would have been sheltered from temperature extremes both in the aquatic and terrestrial habitats. The size of the crevice would preclude removal of turtles by the primary predators on adults in this area, specifically grey fox, black bear, and coyote.

Observations of this type have not been repeated despite frequent checking of similar or potentially similar (e.g., downed logs near the watercourse) microsites in this and several other drainages between 1993 and 1995.

GEOCHELONE GIGANTEA (Aldabra Giant Tortoise). **PREDATION**. On 9 December 1994, a feral cat (*Felis catus*) was killed during a feral goat (*Capra hircus*) control effort on the island of Grande Terre, Aldabra Atoll, Republic of Seychelles. The cat was an adult male, and had the remains of four giant tortoise hatchlings in its stomach. The remains included three heads and thirteen legs, among various other body parts.

Feral cats are known to be predators on giant tortoise (*Geochelone elephantopus*) hatchlings in the Galapagos (MacFarland et al. 1974. Biol. Conserv. 6:118–133), and are major predators of hatchling green sea turtles (*Chelonia mydas*) on Aldabra (Seabrook 1989. J. Zool., Lond. 219:83–88). However, there are no records of feral cats preying on *G. gigantea* hatchlings. Mean clutch sizes for *G. gigantea* on Grande Terre range between 4.0 (±0.6) and 6.1 (±0.5). Tortoises rarely lay more than one clutch annually, and most do not lay every year (Swingland and Coe 1978. J. Zool., Lond. 186:285–309). This single predation event by a feral cat may have accounted for an entire two-year reproductive output of a giant tortoise.

Of the 12 feral cats killed and examined during this project (September 1993–April 1994 and November 1994–May 1995), 10 cats contained the remains of native reptiles. Giant tortoise hatchlings were found in the single cat; three cats contained the remains of green sea turtle (*C. mydas*) hatchlings; and six cats had eaten skinks (*Cryptoblepharus boutonii*) and/or geckos (*Phelsuma abotti abotti* and *Hemidactylus mercatorius*).

LEPIDOCHELYS KEMPII. (Kemp's Ridley Turtle). **FEEDING on INSECTS.** The diets of juvenile, subadult, and adult *Lepidochelys kempii* have been described in several works (Burke et al. 1993. Copeia 1993:1176–1180; Burke et al. 1994. Fish. Bull. 92:26–32; Carr 1942. Proc. New England Zool. Club 21:1–16; DeSola and Abrams 1933. Copeia 1933:10–12; Dobie et al. 1961. Copeia 1961:109–110; Hardy 1962. Cheasapeake Sci. 3:217–220; Lutcavage 1981. M.S. thesis, College William and Mary, Gloucester Point ,Virginia; Lutcavage and Musick 1985. Copeia 1985:449–456; Shaver 1991. J. Herpetol. 25:327–334; Smith and List 1955. Amer. Midl. Nat. 53:115–125). In some of these reports, crabs were the main food item consumed. Investigation of the dried gut contents of a subadult ridley (Auburn University Museum of Paleontology 3086; straight-line carapace = 28.5 cm) found dead on the north shore of Dauphin Island, Mobile County, Alabama, USA in July of 1988 revealed mostly insects. The remains of at least ten grasshoppers (*Shistocera americana*), a dytiscid beetle (*Cybister fembricolatus*), a coreid (*Acanthocephala* sp.), and a pentatomid were identifiable. Additional items eaten were a bryozoan (*Membranipora* sp.), a small mollusk (*Crepidula* sp.), an echinoderm (possibly a sea urchin), a limited amount of unidentified crab parts, and unidentified fish and bird bones, and feathers.

Other than the report by Shaver (*op. cit.*) of a predaceous diving beetle (a dytiscid) and feathers in stomach contents, this is the only report that identifies any of the consumed insects below the family level. This report also provides additional documentation of the ingestion of birds by *L. kempii*.

Because the turtle's carcass was found on the north shore of Dauphin Island, this suggests that it was foraging in relatively shallow and calm waters. It had ingested benthic organisms but evidently was surface feeding on insects which were presumably blown out onto the surface of the water from the coast of mainland Alabama and/or from Dauphin Island. The small amount of fish and bird bones in the turtle's gut indicates that it is unlikely that the insects were indirectly ingested by consuming a fish and/or a bird that had previously eaten them. Additionally, the grasshopper remains were largely intact, suggesting that they had not been earlier ingested by another predator. These data suggest that the diet of *L. kempii* is more diversified than previously thought.

I thank Wayne Clark for his assistance in the identification of the insects, Debbie Folkerts and George Folkerts for their help in identifying the other invertebrate taxa, and Laurie Shepard, then employed by the Department of Biology at the University of South Alabama in Mobile, for providing the skeletal remains of the ridley and the food contained therein.

CROCODYLIA

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **REPRODUCTION.** During 1992 at Brazos Bend State Park, Fort Bend Co., Texas, USA, we observed some unusual phenomena relating to American alligator reproduction. There were two peaks in breeding-related behaviors in 1992, and nesting coincided with the time of the second peak of breeding behavior. This is the first report of more than one peak in breeding-related behaviors within the same year, and of breeding behavior and nesting occurring at the same time in any American alligator population. The courtship and breeding period for *A. mississippiensis* typically lasts ca. two months, and the time between ovulation and nesting is 3–4 weeks (Magnusson et al. 1989. *In* Ross [ed.]., Crocodiles and Alligators, pp. 118–135. Facts On File, New York). At Brazos Bend State Park, courtship and breeding peaked first on 11 May. The first bellow signaling the onset of mating behavior had been heard six weeks earlier. All mating behavior declined after mid-May, and the first nest was found on 17 June. On 18 June there was an intense, sudden onset of bellowing, grouping behavior (especially in pairs), and possible copulation. This second peak lasted through 21 June and abruptly ended.

A total of 21 nests were discovered at Brazos Bend State Park during 1992. Four were devoid of eggs though they physically resembled nests containing eggs. One incomplete nest (sometimes known as a false nest) was discovered in close proximity to a completed nest containing eggs. False nests are different from the fully formed nests without eggs, in that they are unfinished, and often found near a completed nest with eggs. Three nests without eggs were built on 17, 23, and 30 June. The fourth nest without eggs was discovered in a remote area of the park on 15 July; the date it was constructed is unknown. The earliest known nests with eggs were completed 30 June–1 July.

Two of the nests without eggs belonged to mature females whose nesting had been monitored since 1986. One of these nests was built too close to a hiking trail, and we destroyed it due to public safety concerns. The female rebuilt the nest twice, and each time it was destroyed. Three of the nests without eggs were actively defended. The other female built a nest, guarded it for ca. 24 h, then appeared to lose interest and did not respond when the nest was approached by us.

Fully formed nests without eggs have not previously been reported, but in 1990 at Lake George in north-central Florida, ca. 15 such nests were discovered (F. Percival, pers. comm.). These nests were restricted to the northern portion of the lake, and no other eggless nests were found at water bodies being monitored within a 48–64 km radius that year. Nesting took place one week earlier than usual, but there were no abnormal water levels or other unusual conditions discerned which might adversely affect nesting (F. Percival, pers. comm.).

We examined max/min daily temperatures from March–July 1992 to check for any extreme or aberrant patterns, because Joanen and McNease (1979. Proc. Southeast. Assoc. Game Fish Comm. 33:15–19; 1989. Amer. Zool. 29:987–998) found that March–May ambient temperatures were associated with time of nesting. Daily and monthly temperature patterns were compared to long-term data, but there was no apparent correlation between temperature, the second peak of courting, or the occurrence of nests without eggs.

Lance (1984. *In* Webb et al., Wildlife Management: Crocodiles and Alligators, pp. 409–415; Surrey Beatty and Sons, Pty Ltd, New South Wales) listed several environmental factors known to affect reproduction in crocodilians. Water level was one factor that might have influenced mating peaks and/or nesting without eggs being laid. At Brazos Bend State Park, there was flooding from 31 December 1991 to 14 March 1992, with water levels in some areas being 1.2–1.5 m above normal. Separate water bodies were joined by the flooding, resulting in the formation of one large body of water over much of the Park.

Although the proximate cause of the second peak of courting and why females constructed nests without eggs remains elusive, we feel that unusual flooding in 1992 could be related to the phemonena.

LACERTILIA

ANOLIS SAGREI (Brown Anole). **SAUROPHAGY.** Here we report two observations of interspecific saurophagy by adult male brown anoles (*A. sagrei*) on hatchlings of the green anole (*A. carolinensis*). This type of interaction has been previously documented under laboratory conditions (Gerber 1991. Fourth *Anolis* Newsletter, pp. 49–53, Smithsonian Inst., Washington, D.C.), in which predation of juvenile green anoles by adult brown anoles was significantly more frequent than was predation of juvenile brown anoles by adult green anoles or intraspecific predation by either species.

On 13–16 September 1989, 15 adult male brown anoles and 15 adult male green anoles were collected from a one hectare woodlot in Belle Glade, Palm Beach County, Florida, USA and preserved (UTKVZC 05340–05369). Brown anoles and green anoles were found in sympatry at this site and hatchlings of both species were also present on the date of the collection. The anoles were dissected to determine if any juvenile anoles had been taken as prey items. The stomach of one brown anole (UTKVZC 05365; SVL 52 mm) contained a recently consumed hatchling green anole (UTKVZC 05370; SVL 24 mm).

Interspecific predation by a brown anole on a green anole hatchling was observed 14 July 1995 on a dredge spoil island located along the Intracoastal Waterway in the Indian River ca. 4 km N of Ft. Pierce, St. Lucie County, Florida. A hatchling green anole (ca. 20 mm SVL) was captured by hand and gently tossed onto leaf litter beneath an adult male brown anole (SVL 60 mm) perched in a head down position 66 cm above the ground on the trunk of an Australian pine tree (38 cm DBH). The brown anole adjusted its position slightly when the hatchling landed, but the hatchling remained motionless. Thirty-five seconds later the hatchling moved slightly. Immediately thereafter, the brown anole dropped onto the hatchling, took it in its jaws, then returned to within 10 cm of its original position on the tree trunk and consumed the hatchling. After completely consuming the hatchling, the brown anole was noosed, placed into a cooler with ice, then placed in a freezer within four hours. The next day, the brown anole was dissected to confirm the presence of the hatchling, and preserved with the hatchling remaining in the stomach (UFMNH 101601; both specimens verified by David Auth).

To the best of our knowledge, these observations are the first published records of predation by brown anoles on green anole hatchlings in the field. The previous laboratory observations (Gerber, *op. cit.),* together with the field observations reported here, suggest that predation of juvenile green anoles by adult brown anoles could be an important factor in this interaction between a native North American anole and a recently introduced Caribbean species.

Submitted by **TODD S. CAMPBELL** and **GLENN P. GERBER**, Department of Ecology and Evolutionary Biology, University of Tennessee, 569 Dabney Hall, Knoxville, Tennessee 37996, USA. E-mail (TSC): tcampbel@utkux.utcc.utk.edu.

CNEMIDOPHORUS BURTI STICTOGRAMMUS (Giant Spotted Whiptail). **DIET.** T. P. Maslin and party collected several *Cnemidophorus burti stictogrammus* from scrubland habitat in Sonora, México during field trips in 1967 and 1970; these specimens were deposited in the University of Colorado Museum (UCM). We removed and identified stomach contents from these specimens. Three lizards were collected 80 km N Hermosillo along Hwy 15 on 26 July 1967 (UCM 35424, male, SVL = 127 mm; UCM 35428, female, SVL = 118 mm; UCM 35433, male, SVL = 70 mm); two were collected 45 km W Santa Ana along Hwy 2, elev. 580 m, on 24 July 1970 (UCM 42047, male, SVL = 124 mm; UCM 42048, female, SVL = 78 mm). At the first site (N of Hermosillo), the two 100+ mm SVL lizards consumed very large caterpillars (20 mm long) and large scarab beetles (>10 mm long); these comprised the majority of the volume of prey these two lizards consumed even though they both ate many termites (Table 1).

In addition, UCM 35424 also contained unidentifiable plant material (constituting about 10% of the volume of its stomach contents). The small specimen from the first site contained only two small spiders and four small insects. At the second site (W of Santa Ana), both lizards consumed primarily ants and termites (Table 1). However, ants comprised the majority of the volume of prey consumed because UCM 42048 consumed 45 ants (mostly winged adults) and 7 termites, and UCM 42047 consumed 20 very large (15 mm long) ants and 21 small (3.5 mm long) termites. Four of the five lizards contained nematodes (presumably parasites).

TABLE 1. Diet of *Cnemidophorus burti stictogrammus* in Sonora, México. Site 1 was 80 km N Hermosillo (99 prey items from 3 lizards); site 2 was 45 km W Santa Ana (99 prey items from 2 lizards). "No. in Sample" refers to the number of the prey taxon in the stomachs of the lizards from that site.

Submitted by **MARK A. PAULISSEN**, Department of Biological and Environmental Sciences, McNeese State University, Lake Charles, Louisiana 70609, USA, and **JAMES M. WALKER**, Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA.

EUMECES MULTIVIRGATUS (Many-lined Skink). **CLUTCH SIZE.** On 16 June 1993, at Avalon Lake, Eddy County, New Mexico, USA we discovered nine *E. multivirgatus* hatchlings with an attending adult female under a large conglomerate rock (ca. 70 cm diam) on damp, sandy soil. The nest chamber extended downward at a slight angle to a depth of ca. 15 cm, ending in an expanded chamber at the bottom. The opening was ca. 4 cm in diam.

The female measured 66.3 mm SVL, 36.3 mm tail, and weighed 41.0 g. The nine hatchlings ranged in SVL from 25.1–27.1 mm (mean = 26.28, SD = 0.72) and in mass from 0.2–0.5 g (mean = 0.41, SD = 0.07). No egg shells were found. All specimens were preserved and deposited at the University of New Mexico Museum of Southwest Biology (MSB 56179-188).

For 16 published records, clutch size ranged from 3–7 (mean = 3.5) (Smith 1946. Handbook of Lizards. Cornell Univ. Press, Ithaca, New York. 557 pp.; Maslin 1957. Proc. U.S. Natl. Mus. 116:296; Mecham 1967. Southwest. Nat. 12:104; Van Devender 1975. Southwest. Nat. 20:279). Toby J. Hibbitts (pers. comm.) observed a clutch of seven eggs laid by a female collected April 1994 in Crockett County, Texas. Thus, our find exceeds the previous maximum clutch size by two eggs.

WILLIAM GORUM**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

KENTROPYX CALCARATA (NCN). **BEHAVIOR.** During a herpetofaunal survey of the Noel Kempff Mercado National Park (Departamento Santa Cruz, Bolivia), *Kentropyx calcarata* were observed on vegetation and fallen trees along the banks of the Paucerna and Itenez or Guapore Rivers. According to Ávila-Pires (1995, Lizards of Brazilian Amazonia (Reptilia: Squamata) Zoologische Verhandelingen, Leiden 299:1–706), *K. calcarata* "is a forest inhabitant, usually found in open, sunny places . . ." (p. 522).

On 14 December 1995, six individuals were observed near Campamento Las Torres (13°39.308'S, 60°48.710'W). To elude collectors, the lizards would run from one tree to another, and even over the water surface. Their ability to run on water is apparently due to the velocity they attain, because they have no obvious morphological characteristics to enhance this behavior. The longest over water distance observed was 4.5 m; other distances varied from 1.5–2 m. Apparently this is a normal behavior for this species, because many park guards referred to "a lizard walking on the water" before we made our observations.

Kentropyx calcarata was also observed walking underwater along submerged tree trunks. One animal escaped under water in this manner.

Two specimens were collected and deposited in the Museo Noel Kempff Mercado (NKR 843–844) of the Universidad Gabriel Rene Moreno in Santa Cruz de la Sierra, Bolivia.

Submitted by **GUSTAVO J. SCROCCHI**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina, and **LUCINDO GONZALES**, Herpetología, Museo de Historia Natural Noel Kempff Mercado, Casilla N° 2489, Santa Cruz, Bolivia.

MABUYA FRENATA (NCN). **CANNIBALISM.** Although cannibalism among lizards is reported for a number of species of different families (e.g., Diong 1994. Herpetol. Rev. 25:2526; Germano and Williams 1994. Herpetol. Rev. 25:26–27; Rocha 1992. Herpetol. Rev. 23:60 and included references), its incidence is low and may be regarded as opportunistic carnivory (Polis and Myers 1985. J. Herpetol. 19:99–107).

During a study of the rock-dwelling skink *Mabuya frenata* from December 1993 to December 1994 in the Municipality of Valinhos, São Paulo State, southeastern Brazil (22°56'S; 46°55'W), we examined the stomach contents of 239 individuals, two of which contained remains of conspecifics. In the first case, the stomach of a gravid female (84.6 mm SVL, 13.0 g) collected on 26 June 1994 contained a portion of a tail (20.3 mm long) of another adult and no other items. As the owner of that tail may have been too large to be swallowed, this meal could have resulted from an agonistic encounter with no predatory intentions (Vitt 1981. J. Herpetol. 15:454–457). In the second case, another adult female (80.6 mm SVL, 10.4 g) collected on 27 June had the partially digested anterior portion of a newborn individual in its stomach, with no other items present. With the exception of this individual, all of 12 other females collected during that month were gravid, indicating this occurrence of cannibalism coincided with the reproductive season. Moreover, that female showed signs of having given birth recently, which raises the possibility of it having either preyed upon its own progeny or swallowed a stillborn after aborting.

On 23 November 1994, one of us (DV) observed one adult (sex not determined) carrying an apparently dead juvenile crosswise in its jaws while moving up a large boulder. Eventually, it stopped and attempted to swallow its prey, repeatedly changing its hold

on the limp body. After failing this attempt, it carried the body some additional distance along the rock surface and tried again to swallow it. It repeated the process a few more times without success, until it detected the observer's presence and disappeared from view carrying its prey. In October 1993, one of us (DV) made another field observation of an adult carrying a smaller conspecific in its mouth. This time, the prey lizard was being carried by the hind portion of the body and the size difference between predator and prey was less pronounced.

Like other *Mabuya* species, *M. frenata* feeds primarily on arthropods, but is a generalist and opportunistic forager (Vrcibradic 1995. Master's thesis, Universidade Estadual de Campinas, Campinas, São Paulo, Brazil, 72 pp.). We are not aware of any published reports of cannibalism within the genus *Mabuya*, though some Brazilian species are known to prey occasionally on other small lizards (Vitt and Blackburn 1991. Copeia 1991:916–927; Vitt 1995. Occ. Pap. Oklahoma Mus. Nat. Hist. 1:1–29; Vrcibradic and Rocha 1995. Herpetol. Rev. 26:129–131). This suggests that a juvenile conspecific may be viewed as just another potential prey by those skinks, and occasional cannibalism may represent opportunistic foraging in this species.

We thank the Coordenação de Aperfeiçoamento de Pessoal de Ensino Superior (CAPES) for the post-graduate fellowship to D. Vrcibradic and to the Conselho Nacional do Desenvolvimento Científico e Tecnológico (CNPq) for a research grant (Process N° 300819/94-3) to C. F. D. Rocha).

Submitted by **DAVOR VRCIBRADIC** and **CARLOS FREDERICO DUARTE ROCHA**, Setor de Ecologia, Departamento de Biologia Animal e Vegetal, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier, 524, Maracanã, 20550-019, Rio de Janeiro, RJ, Brazil.

UROSAURUS MICROSCUTATUS (Small-scaled Lizard). **TESTIS CYCLE**. The purpose of this note is to report on a histological examination of testes from 13 *U. microscutatus* from southern California, USA. Specimens were examined from the Natural History Museum of Los Angeles County (LACM) 27380, 53630, 97828,97830, 122066,123399, and San Diego Natural History Museum (SDSNH) 504, 505, 714, 48269, 57390, 57394, 57453. All were from San Diego County except for SDSNH 57390 and 57394 which were from Imperial County. Mean SVL was 43 mm + 4 SD mm (range = 38–49 mm). The left testis was removed and embedded in paraffin for histological examination. Sections were cut at 5 µm and stained with hematoxylin followed by eosin counterstain. Four males collected in March were undergoing sperm formation (spermiogenesis). In two of these March males, spermiogenesis was just beginning indicated by groups of metamorphosing spermatids and small sperm clusters. Spermiogenesis was more advanced in the other two March males. The seminiferous tubules were lined by clusters of sperm behind which were several rows of metamorphosing spermatids. Seven males collected in April, one in May, and one in June were all undergoing spermiogenesis. The smallest spermiogenic male measured 38 mm SVL. It appears spermiogenesis begins earlier in the *U. microscutatus* testis cycle than it does in the related *Urosaurus ornatus* from Arizona (Asplund and Lowe 1964. J. Morph. 115:27-34) in which testes were in recrudescent condition during March (spermatogonia and spermatocytes predominate, spermatozoa are absent); spermiogenesis was in progress in *U. ornatus* samples from June.

I thank Robert L. Bezy (Natural History Museum of Los Angeles County) and Gregory K. Pregill (formerly of the San Diego Natural History Museum) for permission to examine *U. microscutatus*.

SERPENTES

AGKISTRODON CONTORTRIX CONTORTRIX (Southern Copperhead). **PREY.** Although predation on lepidopteran larvae by *Agkistrodon c. contortrix* is well known (Fitch 1960. Univ. Kansas Publ. Mus. Nat. Hist. 13:85–288; Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. SSAR, Oxford, Ohio. 614 pp.), few authors have identified such prey to species (Brown 1979. Brimleyana 1:113–124; Palmer, pers. comm. in Gloyd and Conant, *op. cit.*, p.129).

On 2 July 1995 an *A. c. contortrix* was collected on a ranch in Williamson Co., Texas, USA. The specimen was a male with a SVL of 743 mm, tail length of 105 mm, and mass of 399.6 g. On 7 July 1995 this snake excreted the exoskeletons of ca. 14 catalpa sphinx moth larvae, *Ceratomia catalpae* (Sphingidae).These caterpillars sometimes feed in large numbers on the broad leaves of the catalpa tree. The number of larvae consumed by this snake and the lack of other prey traces in its feces indicate that this individual was actively foraging for *Ceratomia catalpae* immediately prior to capture.

Submitted by **ADAM C. WALTERS, DAVID T. ROBERTS**, Department of Herpetology, Dallas Zoo, 621 East Clarendon Drive, Dallas, Texas 75203, USA, and **CHARLES V. COVELL JR.,** College of Arts and Sciences, University of Louisville, Louisville, Kentucky, 40292, USA.

AGKISTRODON CONTORTRIX MOKASEN (Northern Copperhead). **BICEPHALY.** Axial bifurcation has been reported for numerous species of snakes (Cunningham 1937. Axial Bifurcation in Serpents, Duke Univ. Press, Durham, 117 pp.; Smith and Perez-Higareda 1988. Bull. Maryland Herpetol. Soc. 23:139–153; Wallach 1995, Herpetol. Rev. 26:127–129). In the genus *Agkistrodon*, bicephalic (or prodichotomous, Smith and Perez-Higareda, *op. cit.*) specimens are known for *A. blomhoffii* (Inukai 1929. Trans. Sapporo Nat. Hist. Soc. XI, 1:21–24; Nakamura 1938. Mem. College Sci., Kyoto Imperial Univ. ser. B 14:171–191) and *A. piscivorus* (Johnson 1901. Trans. Wisconsin Acad. Sci. Arts Lett. 13:223–236). Strecker (1926. Contrib. Baylor Univ. Mus. 6:10) noted that a captive female *A. contortrix* from Pennsylvania bore a two-headed neonate but provided no other information. Here we describe the first verified bicephalic specimen of *A. contortrix*.

On 10 September 1990 a bicephalic, neonate *A. contortrix* (USNM 498503) was killed in an urban yard (collector unknown) near Charlottesville, Albemarle County, Virginia, USA, and brought to MF. The specimen is a 176 mm snout-vent length female and bears two distinct heads that are joined at the neck immediately posterior to the cranium (Fig. 1). The left head was partially crushed and the body partially severed near the tail when the snake was killed. An X-radiograph revealed that the left head is attached to the primary vertebral axis and that the right head joins the vertebral column five vertebrae posterior to the skull. Four to five vertebrae separate the right skull from the primary vertebral column. Both heads were apparently fully functional at birth without any obvious deformities. There were also no deformities in the vertebral column posterior to the bifurcation at the

neck. This is the first description of a bicephalic specimen of *A. contortrix* (Gloyd and Conant. 1990. Snakes of the *Agkistrodon* Complex, SSAR Contrib. Herpetol. 6).

We are grateful to Tracy Tuberville of the Savannah River Ecology Laboratory for taking the X-radiographs.

Submitted by **JOSEPH C. MITCHELL**, Department of Biology and School for Continuing Studies, University of Richmond, Richmond, Virginia 23173, USA, and **MIKE FIEG,** Virginia Department of Game and Inland Fisheries, P.O. Box 996, Verona, Virginia 24482, USA.

AGKISTRODON PISCIVORUS CONANTI (Florida Cottonmouth). **BROOD DEFENSE.** Brood defense, or the guarding of offspring by one or both parents, is virtually unknown in *Agkistrodon piscivorus* (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. SSAR, Oxford, Ohio. 614 pp.). Wharton (1966. Copeia 1966:154–155) described two instances in which *Agkistrodon piscivorus conanti* females were found in close proximity to their broods and did not disperse when approached. Wharton regarded this as "guarding behavior." No other accounts of such behavior have been reported to our knowledge.

On 22 August 1995 a large adult female *Agkistrodon piscivorus conanti* was found in a cypress swamp ca. 20 miles east of Gainesville in Alachua County, Florida, USA. The specimen was lying at the entrance to a hollow chamber formed by mud, vegetation, and cypress knees. Lying on and around the female were seven neonates. Upon prodding with a field hook, the adult and most of the neonates retreated into the chamber; however, when one of the neonates was touched with the hook the female came back out and oriented toward the hook. The neonate was then picked up and slowly taken away from the chamber entrance. The female quickly followed, tongue-flicking the young snake and hook repeatedly and appearing increasingly agitated. Finally, the neonate fell off the hook and immediately retreated past the female and into the chamber. The female remained at the entrance, oriented toward the hook.

The site was revisited on 25 August 1995. The female was again observed at the entrance to the chamber with two neonates, and similar behavior ensued. This account strongly suggests defense of young by a female *Agkistrodon piscivorus conanti* over an indefinite period of time; however, further investigation under controlled conditions will be necessary to further document this phenomenon.

COLUBER (= MASTICOPHIS) MENTOVARIUS (Tropical Racer). **PREDATION**. At 1300 h on 29 January 1996, we observed an adult male *Coluber (= Masticophis) mentovarius* attempting to consume a juvenile *Boa constrictor*. We made this observation at the Volcan Cacao field station, a site located on the Pacific slope and part of the Guanacaste Conservation Area in Guanacaste Province, Costa Rica. The area surrounding the field station is a mixture of abandoned pasture, secondary forests, and mature primary forest at 1130 m elevation.

The *Coluber* (SVL = 155 cm, weight = 550 g) had grasped the *Boa* (SVL = 50 cm, weight = 66 gm) at midbody and had begun to swallow the posterior 1/4 of the boa's body (Fig. 1). In response, the boa had wrapped the anterior half of its body around the neck of the *Coluber*. This was done in the pattern of an overhand knot so that the *Coluber* was unable to complete the swallowing action. It appeared that the constrictive coil of the boa made it impossible for the *Coluber* to breathe. Furthermore, the boa bit the *Coluber* near its constricting loop. This positioning of the two snakes appeared to be a stalemate. We then captured the two animals for photographic evidence. They remained in this "stalemate" position for ca. 30 min, after which we separated them. This observation represents a novel potential prey item for *Coluber mentovarius* and an unusual antipredator behavioral response by *Boa constrictor*.

We thank the Organization for Tropical Studies for logistic support, students on OTS #96-1 for measurements of specimens, and Jeremy Fox for comments on this note. During this work, M. Laska was supported by a Louis G. Bevier University Fellowship.

HETERODON NASICUS KENNERLYI (Mexican Hognose Snake). **MAXIMUM SIZE.** On 25 September 1995, in the Animas Valley ca. 60 air km S of Animas, Hidalgo County, New

Mexico, USA (31°25'39.15"N 108°50'40.05"W), we (BRT, JPB) collected an adult female *H. nasicus kennerlyi* with the following measurements; 668 mm SVL, 760 mm TL, and 312.2 g. This exceeds the maximum TL of 656 mm reported by Werler (1951 in Boundy 1995. Bull. Chicago Herp. Soc. 30:109–122). The specimen is MSB 59954 in the Division of Herpetology, University of New Mexico.

LAMPROPELTIS GETULA NIGER (Black Kingsnake) **DIET.** Adult *Lampropeltis getula* are known to feed on a variety of prey (Ernst and Barbour 1989. Snakes of Eastern North America. George Mason University Press, Fairfax, Virginia. 282 pp). Although prey types are commonly listed for kingsnakes, there is a paucity of information on specific size of food items utilized in nature. Here we report on predation of two species of snakes by a first year *L. getula niger*.

In 1990 the Clinch River Environmental Studies Organization (CRESO) started a population study of kingsnakes on a 60-ha area located in Anderson County, Tennessee, USA along the Clinch River in the Valley and Ridge physiographic province of eastern Tennessee. On 5 June 1995 we captured a 353 mm (SVL = 304 mm) male *L. getula niger* beneath a cover board located in old field habitat. The kingsnake regurgitated two snakes: a 155 mm *Storeria dekayi wrightorum* (midland brown snake) and a 240 mm *Carphophis amoenus amoenus* (eastern worm snake). Both snakes appeared to have been eaten recently. The three snakes together weighed 16.5 g and the post-regurgitation weight of the kingsnake was 11.5 g.

Out of 290 kingsnake captures, we have recorded only one other case of unforced regurgitation of a food item. On 15 September 1993 a 655 mm (SVL = 570 mm) female *L. getula niger* regurgitated a *Blarina brevicauda* (short-tailed shrew). The snake had a pre-regurgitation weight of 69 g and a post-regurgitation weight of 58.1 g.

We thank the U.S. Department of Energy/Waste Management and Technology Development Division for financial support.

OXYBELIS FULGIDUS (Green Vine Snake). **FEEDING BEHAVIOR.** *Oxybelis fulgidus* is a long, slender colubrid with a pointed head and long tail. Adult length can reach up to 200 cm. This snake is diurnal, arboreally and terrestrially. Although commonly associated with closed forest, it is often observed in open areas. Available data indicate that *O. fulgidus* feeds on lizards (*Ameiva* spp., *Anolis* spp.) and birds (piprid, *Volatina* spp.) (M. Martins, ms.; Zimmerman and Rodrigues 1990. *In* A. Gentry (ed.), Four Neotropical Rainforests, pp. 426–454. Yale Univ. Press, New Haven, Connecticut; Guyer 1994. *In* L. A. McDade et al. (eds.), La Selva: Ecology and Natural History of a Neotropical Rain Forest, p. 382. Univ. Chicago Press, Illinois). It forages in low vegetation or on the ground, where its coloration is effective at concealment.

On 9 November 1995, we observed an *O. fulgidus* foraging for two species of teiid lizards, *Ameiva ameiva* and *Kentropyx calcarata,* in reserve 1401 of the INPA/Smithsonian "Biological Dynamics of Forest Fragments Project" north of Manaus, Brazil. All observations were made from within a man-made clearing in primary forest where the camp facilities are located. These two lizard species are commonly associated with natural forest gaps and therefore also around camps. During three morning hours, we observed five strikes by one juvenile *O. fulgidus* (43 cm SVL, 54 cm TL, 150.5 g). Of these five attempts, three were successful. During the observation period, it moved in the heavy understory and among fallen branches around the edge of the clearing, never entering the clearing. Predatory behavior included a body S-coil, head and neck enlargement, and lunging and striking at moving prey. The size of prey captured was ca. 8 cm SVL.

During the first 45 min of observation, the snake struck twice at young individuals of *A. ameiva* (ca. 8 cm SVL each), and succeeded in both attempts. Five minutes later, the snake struck again, this time at two fighting individuals of *A. ameiva,* attempting to bite the larger one (15 cm SVL). Both lizards escaped, and after a few seconds the larger one came back to face the snake, which remained still. The snake avoided direct confrontation, and the lizard moved away. As the frequency of passing lizards decreased, the snake moved to another perch 6 m away, in a group of fallen branches where a *Kentropyx calcarata* (10 cm SVL) was foraging atop a decaying log. Perceiving the predator's presence, the lizard stopped, and started displaying aggressively towards the snake. Before the snake was able to strike, the lizard fled. After 20 min, the snake captured another juvenile *A. ameiva* (SVL ca. 7 cm). The snake bit the lizard laterally, and used mouth movements to swallow it headfirst as it did with the first two prey.

After this last strike, the snake moved to another perch 3 m away where another *K. calcarata* was foraging. The lizard never came within striking distance. During the next 25 min, the snake positioned itself for two more strikes at two medium-sized *A. ameiva* adults (15 cm SVL). In both instances, the lizards noticed the snake before it was within striking distance. They confronted the snake, and while facing it attracted the snake's attention by shaking their tail. Both lizards stopped displaying after several minutes. During these two encounters, several smaller *A. ameiva* were foraging nearby, but never moved within striking distance. After the second encounter, the snake made its last observed strike at a small juvenile *A. ameiva*, without success.

These observations confirm the sit-and-wait foraging mode of *Oxybelis fulgidus* (M. Martins, unpubl.). Although we did not observe successful predation on *Kentropyx calcarata*, this species has been recorded in the diet of *O. fulgidus* (WAF, pers. obs.).

Submitted by **WAGNER A. FISCHER** and **CLAUDE GASCON**, Ecologia/INPA, CP 478, 69011-970 Manaus, Amazonas, Brazil.

REGINA ALLENI (Striped Crayfish Snake). **PREDATION.** Little information is available on natural predators of *Regina alleni*, an aquatic natricine endemic to peninsular Florida and southern Georgia (Ernst and Barbour 1989. Snakes of Eastern North America. George Mason Univ. Press, Fairfax, Virginia, 282 pp.). Here we report predation on *R. alleni* by a largemouth bass (*Micropterus salmoides*).

On 20 September 1995 between 1330–1400 h, a recreational angler caught a 299 mm standard length *M. salmoides* from a creek emptying into the north side of Lake Manatee reservoir in Manatee County, Florida, USA. The site of capture was ca. 300

m upstream of the lake, where the creek is about 10 m wide. The fish was taken using a 70 mm, dark green, plastic worm fished slowly on the bottom within 1 m of the vegetation bordering the shore, in water about 0.5 m deep. The belly of the fish was visibly distended, and upon dissection, a 330 mm SVL, female *R. alleni* (UF 101061) was recovered from the stomach. The snake showed no signs of digestion, suggesting it had been eaten recently. No other prey were present in the stomach; however, a water hyacinth leaf, crayfish shell fragments, and scales and vertebrae from another natricine snake (probably *Thamnophis* sp.) were found in the intestine.

Godley (1980. Ecol. Monogr. 50:411–436) considered wading birds such as the great blue heron (*Ardea herodias*) and the great egret (*Casmerodius albus*) to be important predators of adult *R. alleni*, especially in shallow marshes, but also described predation by greater sirens (*Siren lacertina*), kingsnakes (*Lampropeltis getula*), cottonmouths (*Agkistrodon piscivorous*), river otters (*Lutra canadensis*), and raccoons (*Procyon lotor*) (Godley 1982. Florida Field Natur. 10:31–36). Ernst and Barbour (*op. cit.*) suggested that alligators (*Alligator mississipiensis*) may also prey on *R. alleni*. Interestingly, fishes previously have not been suggested as potential predators of *R. alleni*, despite the large size and generalized, carnivorous habits of some species. Large *M. salmoides* feed primarily on fish and crayfish, and secondarily on other small vertebrates and large invertebrates (Carlander 1977. Handbook of Freshwater Fishery Biology. Iowa State Univ. Press, Ames, Iowa. 431 pp.). Because *M. salmoides* is abundant throughout Florida and Georgia, it may be a common predator of *R. alleni*.

We thank Walter Szelistowski for donating the specimens and sharing capture data, Gregg Sakowicz for providing information about bass feeding habits, and Steve Godley for improving the manuscript.

REGINA SEPTEMVITTATA (Queen Snake). **REPRODUCTION.** We collected a gravid female *Regina septemvittata* (435 mm SVL, 581 mm TL) from Twelve Mile Creek in Pickens Co., South Carolina, USA on 29 August 1994. This female gave birth to five live offspring on 30 August 1994, and weighed 37.9 g after parturition. No attempt was made to sex the neonates, but all were measured on 1 September 1994. Mean (± SD) SVL, TL, and mass of neonates were 147.6 ± 2.3 (range = 145–150 mm), 205.8 ± 4.5 (range = 201–21 1 mm), and 2.92 ± 0.12 (range = 2.76–3.05 g), respectively. Relative clutch mass (clutch mass / female mass plus clutch mass) was 0.278. The female and neonates were released on 2 September 1994. Our report compliments that of Arndt (1994. Herpetol. Rev. 25:168) who noted that a female collected in Barnwell Co., South Carolina gave birth to nine young on 15 August. Martof et al. (1980. Amphibians and Reptiles of the Carolinas and Virginia. Univ. North Carolina Press, Chapel Hill, 264 pp.) reported litter size ranging from 5–23. In Kentucky, Branson and Baker (1974. Tulane Stud. Zool. Bot. 18:153–171) reported litter sizes of 8–17 with an average of 12.8. For newborns from ten litters (N = 128) from throughout the range, with sexes combined, mean SVL (± SD) and mass were 177 ± 14.6 (range = 134–210 mm) and 3.28 ± 0.48 (range = 2.40–4.22 g), respectively. Parturition dates ranged from 4 August to 10 September.

We thank Joy Schmertman for assistance with measuring snakes and Richard Montanucci for comments on the manuscript.

SYMPHOLIS LIPPIENS (Banded Burrowing Snake). **DIET.** This secretive and fossorial snake is endemic to western México. Little is known about its life history. A DOR male specimen (SVL = 436 mm, tail = 34 mm) was found on Hwy 9, 4.2 mi. E Alamos, Sonora, México at 1900 h on 27 September 1991. Two coleopteran larvae were removed from the stomach. Gene Hall identified them as *Cotinus* or *Euphoria*; Scarabaeidae, Cetoniinae. *Cotinus* is the metallic "fig beetle" that feeds on figs, fruits, bleeding tree sap, etc., as adults. *Euphoria* is a fancy June beetle about which little is known. The larvae of both are probably soil/root feeders.

TANTILLA NIGRICEPS (Plains Black-Headed Snake). **MAXIMUM SIZE and SIZE VARIATION.** On 12 May 1993, a female *Tantilla nigriceps* (SVL = 329 mm, TL = 390 mm; MSB 56035) was collected by Travis Perry and Natalie Runyan in Soccoro Co., New Mexico, USA, on New Mexico Highway 304, 17.7 km N of the junction with U.S. Highway 60. This exceeds the size record of a male (SVL = 320 mm, TL = 384 mm) collected by Hutchins and Myers in Cochise Co., Arizona (Boundy 1995. Bull. Chicago Herp. Soc. 30:109–122.) The next largest specimen in the MSB collection was a female (MSB 16937, TL = 371 mm, SVL = 302 mm) from Bernalillo Co., New Mexico.

All intact *T. nigriceps* specimens at the Museum of Southwestern Biology (N = 133) were measured and examined for sexual dimorphism and geographic variation in TL, SVL, and proportional tail length (PTL = tail length/total length). Small sample size precluded the inclusion of specimens collected outside of New Mexico. All data sets met the assumptions of ANOVA.

Males and females differed significantly with respect to SVL ($t = 2.67$, $df = 131$, $p < .0085$) and PTL ($t = -9.12$, $df = 131$, $p < .001$). Males and females did not differ significantly with respect to TL.

For analysis of geographic variation in size and PTL, specimens were divided into two regions—(1) eastern New Mexico, and (2) central and western New Mexico—based on the natural pattern of distribution of the species in New Mexico (Degenhardt et al. 1996. The Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, New Mexico. 431 pp.). These two regions roughly correspond to the Pecos and Rio Grande drainages, divided by the Guadalupe, Sacramento, Manzano, and Sandia mountain ranges. Central and western specimens were combined due to the small sample of western individuals. A randomized block two-way ANOVA did not show a significant interaction between locality and sex with respect to TL, SVL, or PTL. Each sex was analyzed separately for variation between the eastern and central-western regions.

Males from the central-west region were significantly larger for TL, SVL, and PTL than males from the eastern region (see Table 1). Although females from the central-western region were also larger, on average, than those from the eastern region, the differences were not statistically distinguishable for SVL or TL ($t = -1.49$, $df = 46$, $p < .14$; $t = -1.35$, $df = 46$, $p < .0.18$). In

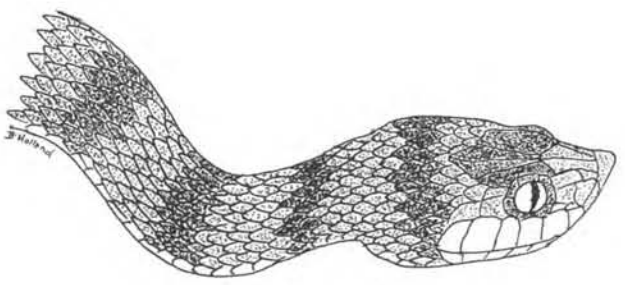
TABLE 1. Measurements of New Mexico *Tantilla nigriceps*. Regions describe general areas of distribution in New Mexico. Values are sample sizes followed by means (standard deviations in parentheses). All measurements are in mm, except PTL. Significantly larger means ($p < .05$) are denoted by bold type.

	Males TL	Females TL	Males SVL	Females SVL	Males PTL	Females PTL
Region	N: mean (SD)	N: mean (SD)	N: mean (SD)	N: mean (SD)	N: mean (SD)	N: mean (SD)
Combined	76: 220 (52.9)	57: 260 (79.8)	76: 172 (41.4)	57: **212** (65.9)	76: **22** (2.3)	57: 18 (2.0)
Central-west	40: **236** (43.7)	39: 270 (74.4)	40: **185** (33.6)	39: 221 (61.5)	40: 21 (2.0)	39: 18 (2.0)
Eastern	29: 207 (55.07)	9: 231 (89.8)	29: 160 (43.4)	9: 186 (73.1)	29: **22** (2.6)	9: **20** (1.9)

contrast to the pattern of body size, females from the eastern region exhibited larger PTL than females from the central-western region, and this difference was statistically significant (see Table 1). However, this pattern may be an artifact of sample size as there were only nine female specimens from the eastern region available for analysis.

In conclusion, males from the central-western region were larger than eastern males. Central-western females were also larger than their eastern conterparts but this difference was not statistically significant. Males had significantly greater tail to body ratios in the eastern region but not in the central western region. This suggests that there may be significant geographic variation in sexual dimorphism in this species.

Submitted by **TRAVIS W. PERRY** and **GRECHEN HAUER**, Museum of Southwestern Biology, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.



THAMNOPHIS PROXIMUS RUBRILINEATUS (Redstripe Ribbon Snake). **REPRODUCTION.** On 18 April 1995, Colorado River Municipal Water District (CRMWD) personnel captured two gravid female *T. proximus rubrilineatus* on the Colorado River, 9.3 km ENE of Doole, Texas, USA. Each snake was measured, weighed, scale clipped for identification, and retained until parturition. Snake #965 measured SVL 503 mm, tail 184+ mm, mass 32.0 g, and had five embryos detected by palpation. Snake #966 measured 504 mm, tail 193 mm, mass 45.0 g, and had nine embryos. Litter sizes range between 4 and 36 for this species (Bowers 1967. Southwest. Nat. 12(2):200; Clark 1974. Herpetologica 30:372–379; Collins 1974. Amphibians and Reptiles of Kansas. Univ. Kansas Mus. Nat. Hist., Publ. Ed. Series No. 1; Fitch 1970. Reproductive Cycles in Lizards and Snakes. Misc. Publ. 52, Univ. Kansas Mus. Nat. Hist. 247 pp.; Smith 1961. The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28(1); Tinkle 1957. Ecology 38:69–77; Wright and Wright 1957. Handbook of Snakes of the United States and Canada. Comstock Publ. Assoc., Ithaca, New York).

On the morning of 3 August between 0800 h and 1200 h, snake #966 gave birth to four healthy and one dead (deformed: spinal anomaly) neonates. Several infertile masses were also expelled during birth. On 9 August, another neonate was born dead. Measurements of the four live neonates were: TL range = 225–236 mm (mean = 232.3; SD = 4.3); SVL range = 158–168 mm (mean = 164.3; SD = 3.9); tail length range = 67–69 mm (mean = 68.0; SD = 1.0); and mass range = 1.6–1.9 g (mean = 1.7; SD = 0.1). In addition to the neonates, five non-fertile masses totalling 1.9 g were expelled during parturition. After parturition on 3 August, female #966 weighed 46.4 g. Her weight on 9 August, following birth of the remaining (dead) neonate, was 43.2 g. The total litter mass, excluding the non-fertile masses, was 9.8 g and the relative clutch mass (RCM = ratio of total litter mass to postpartum female mass + total litter mass) was 0.185.

On 7 August between 0830–1130 h, female #965 gave birth to three neonates and four infertile masses. Of the three fully developed neonates, one was born dead. Their measurements were: TL range = 215–231mm (mean = 225.7; SD = 7.5); SVL range = 163–168 mm (mean = 164.7; SD = 2.4); tail length range = 52–68 mm (mean = 61.0; SD = 6.7); and mass range = 1.6–2.0 g (mean = 1.8; SD = 0.2). The four non-fertile masses totaled 2.0 g. After parturition, female #965 weighed 53.7 g. The total litter mass excluding the non-fertile masses was 5.3 g and the RCM was 0.090, which is unusually low. Both of these RCM's (0.185 and 0.090) are low when compared to a range (0.233–0.370) of other colubrid RCM's previously reported (Plummer 1992. Copeia 1992:1096–1098; Seigel and Fitch 1984. Oecologia (Berl.) 61:293–301; Thornton and Smith 1995. Herpetol. Rev. 26:102–103; Thornton and Smith, in press, Herpetol. Rev.; Tucker and Camerer 1994. Herpetol. Rev. 25:28–29). The timing of both of these births is comparable to that reported previously for this species.

Immediately following birth, all the neonates sloughed their skins. The adult females and six viable young were returned to the capture site and released. We thank the CRMWD for funding and facilities. Collections were made under the authority of the Texas Parks & Wildlife Department Scientific Permit No. SPR-790-208 to CRMWD.

Submitted by **OKLA W. THORNTON, JR.**, and **JERRY R. SMITH,** Colorado River Municipal Water District, HCR 82 Box 4B, Leaday, Texas 76821, USA.

The International Herpetological Symposium Annual Meeting

¡VIVA COSTA RICA!

FOCUS: NEOTROPICAL NATURAL HISTORY AND CONSERVATION

Keynote Speaker: Daniel Janzen, Ph.D.; Banquet Speaker: Michael Fogden, Internationally renowned Wildlife Photographer

Preliminary List of Speakers:
Harry W. Greene, PhD
David L. Hardy, MD
Alejandro Solorzano
J. Alan Pounds, PhD
William R. Branch, PhD
Karl Petersen
William W. Lamar
Norman J. Scott, PhD
Mahmood Sasa
James B. Murphy, DSc
Terry L. Vandeventer
Dante Fenolio

VISA & MasterCard Accepted

Registration: $235.00 (spouse registration $200.00) and includes:
Paper Sessions
Program & Abstracts
Round Trip Transportation between San Jose and Liberia
8 Buffet-Style Meals
Barbecue at Santa Rosa National Park
Banquet Dinner
Other Festivities

Rooms (Hotel Boyeros): $50.00/day (for up to 4 people)

Travel Arrangements:
American Travel Services has guaranteed the lowest possible rates on travel to the 1997 meeting, departing from various gateways across the U.S. and allowing flexibility in travel itineraries. For more information please contact Adam at: American Travel Services, Inc., 800 Brazos, Suite 210, Austin, TX 78701. Telephone: 1-(888) 477-5444 (toll free), (512) 477-2130 (fax). Be sure to mention IHS.

For registration please contact:
David Hulmes, Treasurer
361 Van Winkle Ave.
Hawthorne, NJ 07506
(201) 427-0768

For additional information:
Louis Porras, President
P.O. Box 1957
Sandy, UT 84091-1957
(801) 571-7861

JULY 10-12, 1997

HOTEL BOYEROS, LIBERIA, COSTA RICA

Herpetological Natural History **is a refereed journal published semiannually by the International Herpetological Symposium, Inc. Most articles are written by prominent herpetological authors, and present results or observations concerning the natural history of amphibians and reptiles; they feature topics in ecology, behavior, evolution and systematics, biogeography, paleontology, conservation biology, life history, and regional surveys. Herpetofaunal surveys and studies of species from poorly known regions or regions in danger of human exploitation are particularly featured. Such important contributions often do not make their way into the more data rich, hypotheses driven herpetological journals, and a primary objective of *HNH* is to disseminate such information.**

Subscription to *Herpetological Natural History* is $25.00/yr. for individuals and $50.00/yr. for institutions. International subscriptions are mailed by surface and require an additional $7.00 for postage. Air mail quotes are provided upon request. Back issues (Vol. 1 No. 1 & 2) are available for $34.00/set (postpaid); all other back issues are available for $17.00 ea. (postpaid).

Advances in Herpetoculture **is the first in a series of special publications of specific topics in herpetology. Edited by Peter D. Strimple, this publication contains a foreword by David Chiszar and 25 articles on the husbandry, captive propagation, veterinary medicine, and conservation of amphibians and reptiles. The book has *xiii* + 167 pp., and is generously illustrated with 42 black & white photographs and 30 tables and figures. Cost is $34.95 + $2.00 shipping& handling (foreign orders: $3.00 surface, $10.00 air mail).**

Payment for IHS publications (in U.S. dollars) must be made to International Herpetological Symposium, Inc. VISA & MasterCard are accepted.

ORDER FROM: Allen E. Anderson, Publications Secretary, P.O. Box 176, Norwalk, Iowa 50211 USA

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 27, number 2 (June 1996).

GYMNOPHIONA

CAECILIA MARCUSI (Villa Tunari Caecilian): BOLIVIA: BENI: Provincia Yacuma, 5 km S Totaizal (14°54'S, 66°19'W). 10 February 1995. S. Reichle. Verified by A. Schlüter. Coleccion Boliviana de Fauna, La Paz (CBF 2504). Primary forest at ca. 200 m. Coloration in life: dorsal dark violet, ventral light violet. First department record; northwestward range extension (airline) of ca. 250 km (Duellman 1993, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 21:312).

Submitted by **STEFFEN REICHLE**, Langwiesenstr. 26, D-70771 Leinfelden-Echterdingen, Germany, and **JÖRN KÖHLER**, Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, D-53113 Bonn, Germany.

CAUDATA

AMBYSTOMA MACULATUM (Spotted Salamander). USA: WISCONSIN: Douglas Co: small pond at jct. Summer Road and Minnesuing Road, SW 1/4 NW 1/4 Sec. 16, T46N, R11W. 16 June 1996. Gary S. Casper, Lacey Klucas. Verified by Robert W. Henderson. MPM 27967. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus. 87 pp.) Dead larvae taken from egg mass. Photographs taken of egg mass and included larvae (MPM Photo 535). Extends range ca. 30 km W of localities mapped by Vogt (1981, Natural History of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus. 205 pp.)

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: WISCONSIN: Douglas Co: wetland SE jct. Anderson Road and Francis-Willard Road, NE 1/4 NW 1/4 Sec. 17, T46N, R10W. 17 June 1996. Gary S. Casper, Lacey Klucas and Noa Martinsen. Verified by Robert W. Henderson. MPM 27960. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus. 87 pp.) Individual found in sphagnum moss hummock. Vouchers also taken from three other localities in Douglas County in township T46N R11W (MPM 27961–63). Extends range ca. 30 km W of localities mapped by Vogt (1981, Natural History of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus. 205 pp.)

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA.

ANURA

ACRIS CREPITANS CREPITANS (Northern Cricket Frog). USA: GEORGIA: Monroe Co: Lake Juliette, ca. 0.5 km NE jct. Rum Creek Drive and Ga. Rt. 18. 20 May 1996. J. B. Jensen. Verified by Joshua Laerm. University of Georgia Museum of Natural History (UGAMNH 25012). New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Publ. 3:1–712).

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Wildlife Resources Division, Nongame Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

BUFO ARENARUM (Common Toad). ARGENTINA: CHACO: Resistencia City (27°27'S, 58°58'W). 6 October 1995. Jorge A. Céspedez. Verified by Blanca Beatriz Alvarez. Colección Herpetológica de la Facultad de Ciencias Exactas y Naturale y Agrimensura. (UNNEC 4355–4356). First province record; extends range of species 100 km from record in the northern part of Santa Fé province (Gallardo and Varela de Olmedo 1992, Fauna de Agua Dulce de la Republica Argentina 41:1–116), and represents the northernmost record for the species in the central portion of its range.

Submitted by **JORGE ABEL CESPEDEZ**, Compared Anatomy, Biology Department, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de julio 1449, 3400, Corrientes, Argentina.

BUFO PUNCTATUS (Red-spotted Toad). USA: TEXAS: Floyd Co: Caprock Canyons Trailways State Park, UTM coordinates 14-304470E, 3790854N. 25 June 1996. F. D. Yancey II and K. J. Roberts. Verified by Clyde Jones. The Museum, Texas Tech University (TTU 11624). New county record; fills gap between Briscoe and Garza counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY II** and **KRISTIE JO ROBERTS**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

HYLA CHRYSOSCELIS/VERSICOLOR (Gray Treefrog). USA: MINNESOTA: Otter Tail Co: Sec 19, T34N, R38W. 8 August 1996. Eric Thiss. Verified by Jonathan A. Campbell. UTACV-A 48269. New county record (Oldfield and Moriarty 1994, Amphibians and Reptiles Native to Minnesota. Univ. Minnesota Press, Minneapolis. 237 pp.).

Submitted by **BRICE P. NOONAN**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA.

HYLA SENICULA (Corcovado Treefrog). BRAZIL: MINAS GERAIS: Barão de Cocais (19°56'S, 43°28'W). 14 November 1991. R. N. Feio and L. B. Nascimento. Museu Nacional do Rio de Janeiro (MNRJ 17788–17789, two males). Barão de Cocais. January 1992. R. N. Feio and L. B. Nascimento (MNRJ 17790–17794, four males, one female). Caeté: Lagoa do Cabral (20°00'S, 43°40'W). 8–9 January 1992. L. B. Nascimento (MNRJ 17795–17796, two males). Peçanha (18°30'S, 42°35'W). 1 February 1992. L. B. Nascimento and T. Ballstaedt (MNRJ 17797–17815, 19 males). Guãnhaes (18°46'S, 42°58'W). 31 October 1992. L. B. Nascimento (MNRJ 17816–17836, 21 males). All verified by José Perez Pombal, Jr. Published distribution of the species is coastal region of the states of Rio de Janeiro and Espirito Santo in southeastern Brazil (Frost 1985, Amphibian Species of the World. A Taxonomic and Geographical Reference. Allen Press, Inc., and The Association of Systematics Collections, Lawrence, Kansas, 732 pp.) First documented records for the state of Minas Gerais, occurring in four municipalities; extends distribution ca. 400 km from the coastal region of Brazil.

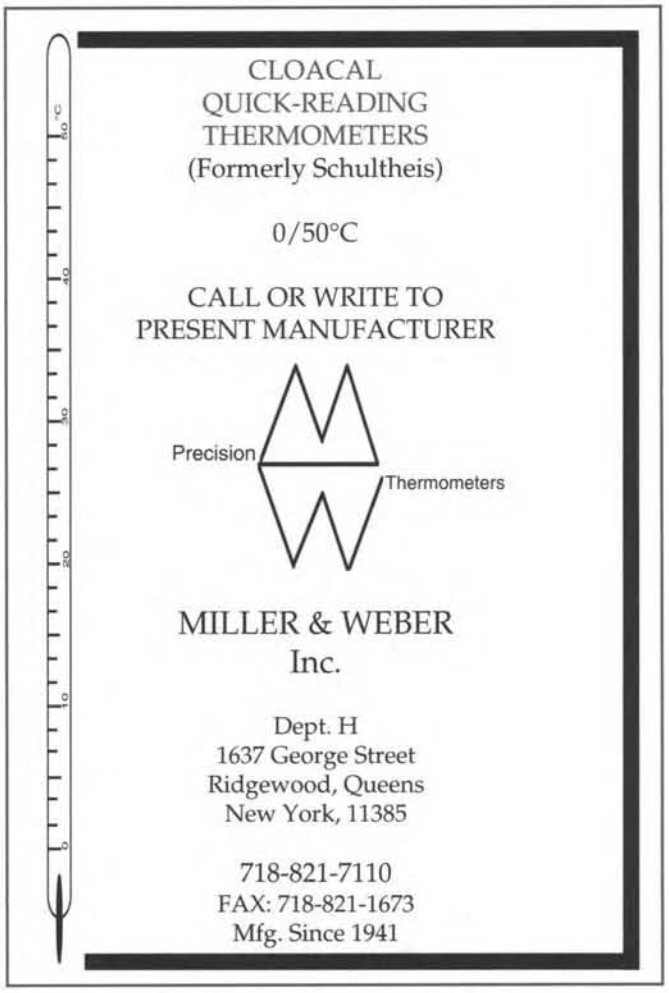
Submitted by **ULISSES CARAMASCHI**, Departamento de Vertebrados, Museu Nacional do Rio de Janeiro, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Rio de Janeiro, Brazil, and **CARLOS ALBERTO GONÇALVES DA CRUZ**,

Departamento de Biologia Animal, Universidade Federal Rural do Rio de Janeiro, 23851-970 Seropédica, Rio de Janeiro, Brazil.

KALOULA PULCHRA PULCHRA (Malaysian Narrowmouth Toad). CHINA: GUANGDONG PROVINCE: Nan Ao Island: Hou Zhai Zhen. 25 July 1996. Yang Si-Chang. Verified by Jose Rosado. MCZ 125851 and South China Normal University Department of Biology 15308. Sixth species of anuran documented for this island [Li and Pan 1995, Chinese Amphibian Biogeography. Herpetol. Ser. (8):125–130] on the Tropic of Cancer 117°E.

Submitted by **JAMES LAZELL** and **WENHUA LU**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835, USA. E-mail: wenhua@uriacc.uri.edu.

PSEUDACRIS TRISERIATA MACULATA (Boreal Chorus Frog) USA: COLORADO: Crowley Co: pond W side of County Road 27, 4.2 mi S of Lincoln County Road D. 4 June 1996. Verified by Hobart M. Smith and David Chiszar. UNC-MNH 278 and UNC-MNH photograph 13. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.).



Submitted by **ENOCH BERGMAN, SCOTT BOBACK, BEN HILL, JUSTIN HOBERT, CHAD MONTGOMERY** and **STEPHEN P. MACKESSY,** Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

RANA BROWNORUM (Brown's Leopard Frog). MÉXICO: QUINTANA ROO: Municipio Othón P. Blanco, 3.5 km N of La Unión (17°56'N, 88°51'W). 6–7 April 1992. Alicia Pérez Nuñez. Verified by Edmundo Pérez Ramos. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 7477–7479); an adult female (MZFC 7478) found in a tree hollow and two juveniles collected on the shore of a small stream in a tropical rain forest. First state record; extends range ca. 327 km SE airline from the closest known locality at 41 mi W Xicalango, Campeche [Sanders 1973. J. Herpetol. 7(2):87–92]. Lee (1980, Univ. Kansas Mus. Nat. Hist. Misc. Publ. 67:1–75) previously reported *Rana pipiens* from the Península de Yucatán but never mentioned *R. berlandieri brownorum*. Hillis (1983, Syst. Zool. 32:132–143) recognized the specific status of *R. brownorum*.

Submitted by **GEORGINA SANTOS-BARRERA, FERNANDO MENDOZA-QUIJANO**, and **ALICIA PÉREZ-NUÑEZ**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, C. P. 04510, Distrito Federal, México.

RANA CATESBEIANA (Bullfrog). USA: COLORADO: Crowley Co: Olney Springs, pond at Olney Springs State Wildlife Area. 14 May, 24 July 1996. Justin Hobert, Enoch Bergman, Chad Montgomery, Ben Hill, Scott Boback. UNC (Univ. Northern Colorado) MNH (formerly CSTC) 157, 270 (numerous others seen); Ordway Reservoir, 4 km N Ordway. 21 July 1996. David Chiszar. UCM 57795. All verified by Todd Gleeson. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.).

Submitted by **JUSTIN HOBERT, ENOCH BERGMAN, CHAD MONTGOMERY, BEN HILL, SCOTT BOBACK** and **STEPHEN P. MACKESSEY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA; **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA; **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado, 80309-0218, USA.

RANA CATESBEIANA (Bullfrog). USA: TEXAS: Sherman Co: cattle tank 1.45 km S and 0.6 km W of Coldwater Creek Bridge on Tex. Rt. 119, 36°14'48"N, 101°49'50"W, 1065.3 m elev. 20 May 1996. T. J. LaDuc, K. and J. Lunt, and S. Waddell. Verified by R. G. Webb. UTEP 16274 (9 tadpoles). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **TRAVIS J. LADUC**, Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **KALEB C. LUNT**, HCR3 Box 47, Sunray, Texas 79086, USA.

RANA SPHENOCEPHALA UTRICULARIA (Southern Leopard Frog). USA: TEXAS: Van Zandt Co: FM Road 47, 6.6 km NE Wills Point. DOR. 17 June 1996. C. J. Franklin and R. L. Gutberlet, Jr. University of Texas at Arlington Collection of Vertebrates (UTA A-48128); FM Road 47, 8.8 km NE Wills Point. AOR. 18 June 1996. C. J. Franklin and R. L. Gutberlet, Jr. UTA A-48129. Both verified by C. L. Stewart. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **CARL J. FRANKLIN**, Dallas Zoo and Aquarium, Reptile Department, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA, and **RONALD L. GUTBERLET JR.**, Department of Biology, The University of Texas at Arlington, Arlington, Texas 76019, USA.

SPEA INTERMONTANA (Great Basin Spadefoot). USA: OREGON: KLAMATH CO: dry lodgepole pine forest 0.2 km east of Yoss Creek. NE 1/4 Sec. 14, T32S, R9E. 21 August 1996. Richard S. Nauman. Verified by William P. Leonard. UMMZ 217118. New county record; westward range extension of ca. 30 km (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Press of Idaho, Moscow. 332 pp.). Specimen was caught at the mouth of a rodent tunnel in a low cut bank of a dirt road.

Submitted by **RICHARD S. NAUMAN**, Chiloquin Ranger District, Winema National Forest, 38500 Highway 97 North, Chiloquin, Oregon 97624, USA, and **THOMAS LOSSEN** and **KEVIN PFEIFER**, 1807 SE 48th, Portland, Oregon 97215, USA.

ZACHAENUS PARVULUS (Rio Bug-eyed Frog). BRAZIL: SÃO PAULO: Picinguaba (44°52'W, 23°22'S), Ubatuba Municipality. 9 November 1995. A. A. Giaretta. Verified by I. Sazima. Museu de História Natural da UNICAMP (ZUEC 9548). New state record; southernmost known locality (Cochran 1955, Frogs of Southeastern Brazil. U.S. Natl. Mus. Bull. 206:1–423). Individuals found from 100 to 850 m asl.

Submitted by **ARIOVALDO A. GIARETTA** and **RICARDO J. SAWAYA**, Univ. Est. de Campinas, Inst. Biol., Dep. Zool. CP 6109, 13083-970, Campinas, São Paulo, Brazil.

TESTUDINES

ACANTHOCHELYS PALLIDIPECTORIS (Chaco Sideneck Turtle). PARAGUAY: ÑEEMBUCU: Paso Lengá, 7 km SE Pilar City (26°52'S, 58°23'W). 15 September 1992. A. Giraudo and R. Miatello. Verified by Mario R. Cabrera. Herpetological collection of PROBBAS, Consejo Nacional de Investigaciones Científicas y Técnicas, Corrientes, Argentina (CFA 85, carapace and plastron of adult). First definite record for Paraguay; extends range ca. 100 km airline east from the nearest known population in Resistencia, Argentina. *Acanthochelys pallidipectoris* was known only from the Argentine Chaco in Santa Fé, Formosa, Salta and Chaco provinces (Freiberg 1945, Phisys 20:19–23; Ernst 1983, Cat. Am. Amphib. Rept. 325.1; Waller 1988, Amphib. Reptil. (Conserv.) 1:93–98; Richard and De la Fuente 1992, Acta Zool. Lilloana 41:360). Ernst (*op. cit.*) indicated its possible occurence in Paraguay based on a mention of "*Platemys spixii*" by Schenkel (1901, Verh. Naturforsch. Ges. Basel 13:142–199), a synonym of *Acanthochelys pallidipectoris* (Rhodin et al. 1984, Copeia 1984:780–786). However, the site mentioned by Schenkel (*op. cit.*), "Apalue," cannot be found on any maps available to me.

Submitted by **ALEJANDRO R. GIRAUDO**, Becario de CONICET, Instituto Nacional de Limnologia, José Maciá 1933, 3016, Santo Tomé, Santa Fe, Argentina.

CHRYSEMYS PICTA BELLII (Western Painted Turtle) USA: COLORADO: LAS ANIMAS CO: pond S side of County Road 72.5 (along Two Butte Creek), 1.0 mi W Baca/Las Animas County line. Verified by Hobart M. Smith and David Chiszar. UNC-MNH photographs 15–16. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.).

Submitted by **SCOTT BOBACK, SHELLEY LINK, CHAD MONTGOMERY, JUSTIN HOBERT, ENOCH BERGMAN, BEN HILL** and **STEPHEN P. MACKESSY,** Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

CLEMMYS MUHLENBERGII (BOG TURTLE). USA: NORTH CAROLINA: MITCHELL CO: 3.1 km SW Bakersville. 12 August 1996. Elizabeth Hunter. Verified by Jeffery C. Beane. North Carolina State Museum of Natural Sciences (NCSM 96-8-19; DWH 96.20). New county record; fills gap between the nearest records from Avery County (Palmer and Braswell 1995, Reptiles of North Carolina. Univ. North Carolina Press. Chapel Hill. xii + 412 pp.) and Yancey County (Herman 1986, Herpetol. Rev. 17:50).

Submitted by **DENNIS W. HERMAN**, North Carolina State Museum of Natural Sciences, P.O. Box 29555, Raleigh, North Carolina 27603, USA, **ELIZABETH HUNTER**, Route 3, Box 99-D, Bakersville, North Carolina 28705, USA, and **CHRIS MCGRATH**, North Carolina Wildlife Resources Commission, 315 Morgan Branch Road, Leicester, North Carolina 28748, USA.

TRIONYX SPINIFERUS PALLIDUS (Pallid Spiny Softshell). USA: TEXAS: GARZA CO: Double Mountain Fork of Brazos River, just W bridge-crossing of Farm Road 669 (S Post) 33°00'46"N, 101°24'14"W, 739.7 m elev. 20 May 1996. R. W. Axtell and R. G. Webb. Verified by C. S. Lieb. KU Color Slide 11234. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **ROBERT G. WEBB**, Laboratory for Environmental Biology, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **RALPH W. AXTELL**, Department of Biological Sciences, Southern Illinois University at Edwardsville, Edwardsville, Illinois 62026, USA.

SAURIA

AMEIVA UNDULATA (Rainbow Ameiva). MÉXICO: QUERÉTARO: Municipality of Landa de Matamoros, Tangojo, 24 km SE of Landa de Matamoros (21°05'N, 99°05'W), 460 m elev. 19 May 1995. Ulises Padilla García. Verified by Adrián Nieto Montes de Oca. Laboratorio de Zoología, Universidad Autónoma de Querétaro (BUAQ 86, formerly UPGH 102). Adult male found in tropical deciduous forest. First state record; extends range ca. 30 km SSW from the closest known locality in the Xilitla region, San Luis Potosí (Echternacht 1971, Univ. Kansas Mus. Nat. Hist. Misc. Publ. 55:1–86).

Submitted by **ULISES PADILLA GARCÍA**, Laboratorio de Zoología, Universidad Autónoma de Querétaro, Centro Universitario S/N, Colonia Centro, Apartado Postal 184, C. P. 76017, Querétaro, México, and **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, C. P. 04510, Distrito Federal, México.

ANOLIS CAROLINENSIS (Green Anole). USA: TEXAS: TOM GREEN CO: San Angelo. 2 July 1996. J. F. Husak. Verified by T. C. Maxwell. Angelo State Natural History Collection (ASNHC 12887). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JERRY F. HUSAK**, Department of Biology, Angelo State University, San Angelo, Texas 76909, USA.

DIBAMUS BOGADEKI (Bogadek's Blind Skink). CHINA: HONG KONG TERRITORY: Chau Kung To (Sunshine Island), ca 9 km WSW Victoria. 8 July 1996. P. Lynch. MCZ 181758. Verified by Michael Lau. Fourth known specimen and third known island. In addition to the type-locality, Hei Ling Chau (Darevsky 1992, Asiatic Herpetol. Res. 4:8), this species occurs on Shek Kwu Chau (Zhao and Adler 1993, Herpetology of China, SSAR:

Plate 27E; MCZ 177136, 179502), ca 20 km SW Victoria. All of these islands are threatened by either destructive development or consumption for reclamation projects elsewhere.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Concho Co: Eden. 24 September 1994. R. Rodgers and K. Pfluger. Angelo State Natural History Collection (ASNHC 12883). Tom Green Co: San Angelo. 8 March 1990. Shannon Jones. Angelo State natural History Collection (ASNHC 12676). Both verified by T. C. Maxwell. New county records for this introduced species (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JERRY F. HUSAK**, Department of Biology, Angelo State University, San Angelo, Texas 76909, USA.

LAEMANCTUS SERRATUS SERRATUS (Serrated Casquehead Iguana; Lemacto Coronado). MÉXICO: QUERÉTARO: Municipality of Landa de Matamoros, Tangojo, 24 km SE of Landa de Matamoros (21°05'N, 99°05'W), 580 m elev. 19 May 1995. Ulises Padilla García. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de Mexico (MZFC 7360 juv male); 25 July 1995. Ulises Padilla García (MZFC 7527, adult female) and Laboratorio de Zoología, Universidad Autónoma de Querétaro (BUAQ 098, adult male). All verified by Adrián Nieto Montes de Oca. Specimens were found in tropical subdeciduous forest and represent the first records for Querétaro, extending the range ca. 30 km SSW from the closest known locality at Xilitla, San Luis Potosí [Taylor 1949, Univ. Kansas Sci. Bull. 33(2):169–215; McCoy 1968, Copeia 1968:665–678].

Submitted by **ULISES PADILLA GARCÍA**, Laboratorio de Zoología, Universidad Autónoma de Querétaro, Centro Universitario S/N, Colonia Centro, Apartado Postal 184, C. P. 76017, Querétaro, México, **WALTER SCHMIDT BALLARDO** and **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, C. P. 04510, Distrito Federal, México.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). USA: TEXAS: Hall Co: Caprock Canyons Trailways State Park, UTM coordinates 14-345566E, 3820296N. 26 June 1996. F. D. Yancey, II and K. J. Roberts. Verified by Clyde Jones. The Museum, Texas Tech University (TTU 11626). New county record; fills gap between Briscoe and Childress counties (Dixon 1987, Amphibians of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY II** and **KRISTIE JO ROBERTS**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

PHYLLOPEZUS POLLICARIS PRZEWALSKYI (Brazilian Gecko). ARGENTINA: FORMOSA: Departamento Matacos: Ingeniero G. N. Juarez (23°54'S, 61°46'W). 25 February 1991. R. Aguirre, B. B. Alvarez, A. Hernando, M. Tedesco. Coleccion Herpetologica de la Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC 1002); Tte. Gral R., M. Fraga (23°45'S, 62°08'W), same date and collectors (UNNEC 1004). Verified by A. Hernando. First province records, extend range 150 km NNW of previous records in Chaco Province, Argentina. [Cei 1993, Monogr. XI, Mus. Reg. Sci. Nat. Torino: 1–949; Alvarez B. 1988, Rev. Asoc. Cs. Nat. Lit. 19(1):79–89] and 180 km NE of previous record in Salta Province (Cruz et al. 1994, Herpetol. Rev. 25:161).

Submitted by **BLANCA BEATRIZ ALVAREZ**, Catedra de Anatomia Comparada, Departamento de Biologia, Facultad de Ciencias Exactas y Naturales, Universidad Nacional del Nordeste, 9 de Julio 1449, 3400 Corrientes, Argentina.

PHYLLOPEZUS POLLICARIS PRZEWALSKYI (Brazilian Gecko). PARAGUAY: DEPARTAMENTO PARAGUARI: Chololo (25°30'S, 57°W). 3 March 1989. M. Culzzoni and B. Alvarez. Verified by A. Hernando. Coleccion Herpetologica de la Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC 1005). First department record (Aquino et al. 1996, in Colec. Flora y Fauna Mus. Nac. Hist. Nat. Parag., Ed. O. Romero Martinez,1996:331–400).

Submitted by **MERCEDES CULZZONI**, Division de Anatomia Comparada, Departamento de Biologia, Facultad de Ciencias Exactas y Naturales, Universidad Nacional de Asuncion. San Lorenzo, Paraguay, and **BLANCA BEATRIZ ALVAREZ**, Catedra de Anatomia Comparada, Departamento de Biologia, Facultad de Ciencias Exactas y Naturales, Universidad Nacional del Nordeste, 9 de Julio 1449, 3400 Corrientes, Argentina.

STENOCERCUS MARMORATUS (Spotted Whorltail Iguana). ARGENTINA: SALTA: Santa Victoria Department: Baritú National Park, Cuesta Los Coloraditos (22°34'S, 64°38'W). 9 September 1981. Omar Pagaburo and Enrique Terán. Verified by Gustavo J. Scrocchi. Herpetological collection from the Instituto de Herpetología, Fundación Miguel Lillo, Tucumán (FML 01130–01131, 4 specimens). First record for country; Cei (1993, Reptiles del Noroeste, Nordeste y Este de la Argentina. Herpetofauna de las Selvas Subtropicales Puna y Pampas. Mus. Reg. Sci. Nat. Torino, Monogr. 14:1–949) does not mention this species for Argentina. Collected in Yunga habitat, this population is sympatric, not syntopic, with *S. roseiventris*. Fritts (1974, San Diego Soc. Nat. Hist. Mem. 7:86 pp.) commented that this species inhabited Andean slopes between 2700 and 3350 m, in Cochabamba Department, Bolivia. The locality reported here is at ca. 1600 m elevation and extends range 1500 km to the south from type locality at Cochambamba.

Submitted by **FÉLIX B. CRUZ**, **GUSTAVO J. SCROCCHI**, and **SILVIA A. MORO**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, (4000) Tucumán, Argentina.

STENOCERCUS PECTINATUS (Whorltail Iguana). ARGENTINA: CORDOBA: Departamento Rio Cuarto: Laguna Oscura (33°53'S, 64°42'W). 10–28 October 1993. L. Cardinale and P. Vignolo. Verified by Ricardo Martori. Herpetological collection of Zoologia de Vertebrados, Departamento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Cordoba, Argentina (ZV-UNRC 2553, 2555, 2745). First department record, 320 km S of the previous record for the province.

Submitted by **LISANDRO CARDINALE** and **PABLO VIGNOLO**, Departamento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Estado Postal Nro. 9, C. P. 5800, Rio Cuarto, Cordoba, Argentina.

UROSAURUS ORNATUS WRIGHTI (Northern Tree Lizard). USA: COLORADO: Routt Co: Pagoda Cemetery. 3 August 1996. H. M. Smith. Verified by Richard L. Holland. UCM 57800. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.), and the easternmost limit of range known in the state.

Submitted by **HOBART M. SMITH** and **DAVID CHISZAR,** University of Colorado Museum, Boulder, Colorado 80309-0218, USA; and **JAN J. ROTH**, Sundance Research Institute, 417 Breeze Street, Craig, Colorado 81625, USA.

UROSTROPHUS GALLARDOI (Steppe Iguana). BOLIVIA: TARIJA: borders of Tarija river, entry to Salinas coming from Potrerillos, Reserva Natural de Flora y Fauna de Tariquia (21°56'41.5"S, 64°19'9.6"W), 870 m. 24 October 1995. Gustavo Scrocchi. Verified by Fernando Lobo. Coleccion Boliviana de Fauna, La Paz, Bolivia (CBF 1731). First department record; second record from Bolivia where it was only known from Santa Cruz de la Sierra (Etheridge and Williams 1991, Bull. Mus. Comp. Zool. 152(5):317–361).

Submitted by **SEBASTIAN ENRIQUE TORRES**, Instituto de Herpetologia, Fundacion Miguel Lillo, Miguel Lillo 251, 4000, Tucuman, Republica Argentina.

SERPENTES

ARIZONA ELEGANS ELEGANS (Kansas Glossy Snake). USA: TEXAS: Floyd Co: 4 mi. S, 1 mi W Quitaque, UTM coordinates 14-304470E, 3790854N. 25 June 1996. F. D. Yancey, II and K. J. Roberts. Verified by Clyde Jones. The Museum, Texas Tech University (TTU 11625). New county record; fills gap between Briscoe and Crosby counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY II** and **KRISTIE JO ROBERTS**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

CHIRONIUS LAEVICOLLIS (Brazilian Cipó). BRAZIL: SÃO PAULO: BAHIA: Ubaitaba (14°18'S, 39°20'W, 0–100 m elev.). 1 August 1994. G. Brisolla. Verified by Francisco L. Franco. Instituto Butantan (IB 55468). This species is found in the Atlantic Forest, along the southeastern coast of Brazil from the state of Espirito Santo and Minas Gerais to Santa Catarina. (Dixon et al. 1993, Revision of the Neotropical Snake Genus *Chironius* Fitzinger (Serpentes, Colubridae). Mus. Reg. Sci. Nat. Monogr. XIII, 280 pp.). The northern limit of its range was reported as Santa Leopoldina, ES (20°06'S, 40°32'W) (Dixon et al., *op. cit.*, p. 137). First documented record for the state of Bahia; extends distribution northward.

Submitted by **OTAVIO A. V. MARQUES** and **GIUSEPPE PUORTO**, Laboratório de Herpetologia, Instituto Butantan. Avenida Vital Brazil, 1500, CEP 05503-900, São Paulo, São Paulo, Brazil.

DRYADOPHIS MELANOMUS VERAECRUCIS (Olive Lizard Eater). MÉXICO: HIDALGO: Municipality of Tenango de Doria, 3 km W Tenango de Doria way to El Texme (20°20'09"N, 98°15'97"W), elev. 1065 m. 29 June 1995. Roberto C. Monroy Ibarra and Fernando Mendoza Quijano. Verified by Adrián Nieto Montes de Oca. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 7759). Adult female found near small stream in cloud forest. First record for state of Hidalgo; extends range ca. 16 km SE from the closest known locality at Zacualpan, Veracruz (Stuart 1941, Univ. Michigan Mus. Zool. Misc. Publ. 49:1–106).

Submitted by **ROBERTO C. MONROY IBARRA, SOL DE MAYO MEJENES LOPEZ**, and **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, C. P. 04510, Distrito Federal, México.

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). USA: TEXAS: Roberts Co: 7.56 km (by road) NE jct US Rt. 60 and Tex. Rt. 282 (in Miami) on US Rt. 60, 35°44'05"N, 100°34'30"W, 810.8 m elev. 19 May 1996. T. J. LaDuc, D. I. Lannutti, and J. D. Johnson. Verified by C. S. Lieb. UTEP 16270. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **DOMINIC I. LANNUTTI** and **TRAVIS J. LADUC**, Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998, and Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

EPICRATES CENCHRIA MAURUS (Rainbow Boa; Boa Tornasol). VENEZUELA: ESTADO MERIDA: 1 km from Alcabala de Puente Victoria on road from Mérida to Santa Cruz de Mora. 16 May 1988. Jesús Molinari and Juan Luis Concepción. Colección de Anfibios y Reptiles, Laboratorio de Biogeografía, Escuela de Geografía, Universidad de Los Andes (ULABG) 2051; Laguna de Caparú, 25 km SW Mérida, 900 m elev. 12 November 1992. Pascual Soriano. ULABG 3926 (photograph and shed skin). Both verified by Pascual Soriano. First records for the state of Mérida and the Venezuelan Andes (Roze 1966, La Taxonomía y Zoogeografía de los Ofidios de Venezuela, Caracas, Ediciones de la Biblioteca 28:64–66). These specimens were previously reported as *Epicrates cenchria cenchria* by La Marca and Soriano (1995, Herpetol. Rev. 26:109). Further examination of ventral scale counts and color pattern indicate that they represent *E. cenchria maurus*.

Submitted by **ROBERTO CASADO B.**, Universidad de Los Andes, Facultad de Ciencias, Ecología Animal, La Hechicera, Apartado Postal 71, Mérida 5251, Venezuela, and **ENRIQUE LA MARCA**, Universidad de Los Andes, Facultad de Ciencias Forestales y Ambientales, Escuela de Geografía, Apartado Postal 116, Mérida 5101-A, Venezuela.

HETERODON NASICUS (Western Hognose Snake). USA: COLORADO: Douglas Co: Roxborough State Park. July 1987. Cecilia A Travis. Verified by Alan de Queiroz. UCM Color Slides 127–128. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.).

Submitted by **CECILIA A. TRAVIS**, Roxborough State Park, 4751 North Roxborough Drive, Littleton, Colorado 80125, USA, and **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

HYDROPS TRIANGULARIS (Triangle Water Snake). BRAZIL: MARANHÃO: Arari (03°28'S, 44°47'W). 23–24 November 1985. D. F. Moraes Jr. Verified by José Perez Pombal Jr. Museu Nacional do Rio de Janeiro (MNRJ 4497). First documented record for state of Maranhão in northeastern Brazil; extends range ca. 240 airline km SE of record from Colônia Nova, state of Pará, Brazil (Cunha and Nascimento 1978, Ofidios da Amazonia. X. As cobras da região leste do Pará. Museu Paraense Emilio Goeldi, Publ. Avulsas 31:218 pp.); easternmost record for South America. According to Roze (1957, Acta Biologica Venezuelica 2:51–95), identified as *Hydrops triangularis triangularis*, a subspecies restricted to the eastern part of the Amazonian basin; the present locality record, in the Mearim River drainage, is isolated from the Amazonian basin.

Submitted by **HUSSAM ZAHER** and **ULISSES CARAMASCHI**, Departamento de Vertebrados, Museu Nacional do Rio de Janeiro, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Rio de Janeiro, Brazil.

HYPSIGLENA TORQUATA DESERTICOLA (Desert Night Snake) USA: IDAHO: Butte Co: Idaho National Engineering Laboratory, Crater Butte: UTM Zone 12: 326464.127 E, 4829086.369 N. 23 June 1995. Sarah L. Cooper. Verified by Charles R. Peterson. Idaho Museum of Natural History (IMNH 1481–82). Three individuals caught in a drift fence array; two were collected. New county record (Nussbaum et. al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press., Moscow. 332 pp.); represents range extension of over 50 miles for this species, which had not been detected on INEL in the past 20 years despite repeated herpetological surveys and projects. Drift fences have been shown to be an effective means of capturing secretive and/or nocturnal herpetofauna on the INEL.

Submitted by **SARAH L. COOPER**, Department of Biological Sciences, Idaho State University, Campus Box 8007, Pocatello, Idaho 83209, USA.

HYPSIGLENA TORQUATA JANI (Texas Night Snake). USA: TEXAS: Roberts Co: 2.09 km (by road) NW jct Tex. Rt. 283 and Tex. Rt. 283 (ca. 4.34 road km NW Miami), 35°42'00"N, 100°40'38"W, 859.5 m elev. 18 May 1996. T. J. LaDuc, D. I. Lannutti, and J. D. Johnson. Verified by C. S. Lieb. UTEP 16285. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **DOMINIC I. LANNUTTI** and **TRAVIS J. LADUC**, Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998, and Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

HYPSIGLENA TORQUATA LOREALA (Mesa Verde Night Snake). USA: COLORADO: Garfield Co: 1.6 km E Parachute, base of Naval Oil Shale Reserve. 30 June 1995. John A. Rybak. UCM Herpetological Photograph No. 129. Verified by Richard L. Holland. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.).

Submitted by **JOHN A. RYBAK**, 177 Sagemont Circle, Parachute, Colorado 81635, USA; **LAUREN J. LIVO**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA; **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

IMANTODES GEMMISTRATUS (Central American Tree Snake). MÉXICO: QUERÉTARO: Municipality of Landa de Matamoros, Tangojo, 24 km SE of Landa de Matamoros (21°05'N, 99°05'W), 550 m elev. 7 March 1995. Ulises Padilla García. Verified by Adrián Nieto Montes de Oca. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 7547). Juvenile collected in tropical deciduous forest. First state record; extends range ca. 122 km SE of the closest known locality, 33 mi S Tampico, Veracruz [Reese 1971, J. Herpetol. 5:67–69].

Submitted by **ULISES PADILLA GARCÍA**, Laboratorio de Zoología, Universidad Autónoma de Querétaro, Centro Universitario S/N, Colonia Centro, Apartado Postal 184, C. P. 76017, Querétaro, México, and **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, C. P. 04510, Distrito Federal, México.

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake). USA: TEXAS: Rains Co: County Road 1480 near Sabine River Authority Headquarters, ca. 5 km S Hermits Cove. AOR. 17 June 1996. R. L. Gutberlet, Jr. and C. J. Franklyn. Verified by C. L. Stewart. University of Texas at Arlington Collection of Vertebrates (UTA-R 39883). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **RONALD L. GUTBERLET JR.**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA, and **CARL J. FRANKLIN**, Dallas Zoo and Aquarium, Reptile Department, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA.

LAMPROPELTIS GETULA (Common Kingsnake) USA: COLORADO: Las Animas Co: within vertical crevice in bluffs on S side of West Carrizo Creek, ca. 50 m E jct County Road 22.1. 1 August 1996. Verified by Hobart M. Smith and David Chiszar. UNC-MNH 279 (shed skin). First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.). Specimen is an intergrade between *L. g. splendida* and *L. g. holbrooki*.

A second specimen (partial carcass; UNC-MNH 3280) was found at the following location: Otero Co: side creek at jct West 5th and Maple Streets in La Junta. 1 August 1996. The occurrence of *L. getula* in eastern Colorado has been somewhat speculative, since the only other record was also from the town of La Junta (Hammerson 1986, Amphibians and Reptiles in Colorado. Publ. Colorado Division of Wildlife), raising the possibility of an introduction. This second record from La Junta suggests that the population is indeed natural, and the Las Animas record, at a very remote rural locality, confirms the natural presence of this snake in Colorado.

Submitted by **SCOTT BOBACK, SHELLEY LINK, ENOCH BERGMAN, BEN HILL, CHAD MONTGOMERY, JUSTIN HOBERT** and **STEPHEN P. MACKESSY,** Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

LAMPROPELTIS TRIANGULUM CELAENOPS (New Mexico Milk Snake) USA: NEW MEXICO: Grant Co: 10 mi W Silver City (Mangas Valley, Sec. 20, T18S, R16W). May 1961. Dale A. Zimmermann. Verified by Stanley P. Fields. Western New Mexico University (WNMU 45). New county record; extends range ca. 145 km NNE and 122 km NW from nearest records (Degenhardt et al. 1996, Amphibians and reptiles of New Mexico. Univ. New Mexico Press. xix + 431 pp).

Submitted by **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game and Fish, P. O. Box 25112, Santa Fe, New Mexico 87504, USA, and **RANDY D. JENNINGS**, Department of Natural Sciences, Western New Mexico University, Silver City, New Mexico 88062, USA.

LEPTOPHIS MEXICANUS SEPTENTRIONALIS (Tamaulipan Parrot Snake). MÉXICO: QUERÉTARO: Municipality of Landa de Matomoros, Tangojo, 24 km SE de Landa de Matomoros

(21°05'N, 99°05'W), 450 m elev. 18 May 1995. Ulises Padilla García. Verified by Adrián Nieto Montes de Oca. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 7548). A juvenile caught near the shore of the Moctezuma River in tropical deciduous forest; first state record and extends range ca. 102 km S of the closest known locality at Gustavo Garmedia (15 km N Ciudad Valles), San Luis Potosí by Mancilla and Schmidt (1995, Herpetol. Rev. 26:156).

Submitted by **ULISES PADILLA GARCÍA**, Laboratorio de Zoologia, Universidad Autónoma de Querétaro, Centro Universitario S/N, Colonia Centro, Apartado Postal 184, C. P. 76017, Querétaro, México, and **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, C. P. 04510, Distrito Federal, México.

LEPTOTYPHLOPS DULCIS DULCIS (Plains Blind Snake). USA: TEXAS: Cottle Co: Matador Wildlife Management Area. 15 June 1995. Janelda E. Chavez. WTAMU 15030-1. Verified by Anthony I. Mazeroll. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press. 434 pp.).

Submitted by **KATHLEEN B. BLAIR** and **JANELDA E. CHAVEZ**, Department of Biology and Geosciences, West Texas A&M University, Canyon, Texas 79015-0808, USA; **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

MASTICOPHIS FLAGELLUM TESTACEUS (Western Coachwhip). USA: TEXAS: Hansford Co: 0.64 km (by road) N jct. Tex. Rt. 15 and FM 1573 on Tex. Rt. 15, 36°16'13"N, 101°35'51"W, 1028.7 m elev. 16 May 1996. D. I. Lannutti and T. J. LaDuc. Verified by R. G. Webb. UTEP 16291. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **DOMINIC I. LANNUTTI** and **TRAVIS J. LADUC**, Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998, and Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

SIBYNOMORPHUS LAVILLAI (LaVilla's Tree Snake). ARGENTINA: SANTIAGO DEL ESTERO: Departamento Copo: Pampa de los Guanacos (26°14'S, 61°49'W). 12 December 1995. A. Hernando, M. Lions and R. Aguirre. Verified by L. Rey. Coleccion Herpetologica de la Universidad Nacional del Nordeste, Corrientes, Argentina. (UNNEC 4571–73, 4575, 4941–42). First province record [Scrocchi et al. 1993, Rev. Brasil. Biol. 53(2):197–208].

Submitted by **MARIA LUISA LIONS** and **BLANCA BEATRIZ ALVAREZ**, Catedra de Anatomia Comparada, Departamento de Biologia, Facultad de Ciencias Exactas y Naturales, Universidad Nacional del Nordeste, 9 de Julio 1449, 3400 Corrientes, Argentina.

SIBYNOMORPHUS VENTRIMACULATUS (Boulenger's Tree Snake). ARGENTINA: CORRIENTES: Departamento Ituzaingo: Colonia Liebig (27°55'S, 55°50'W). 22 April 1996. M. Chatellenas. Verified by L. Rey. Coleccion Herpetologica de la Universidad Nacional del Nordeste, Corrientes, Argentina. (UNNEC 4881). First province record [Scrocchi et al. 1993, Rev. Brasil. Biol. 53(2):197–208].

Submitted by **MARIA LUISA LIONS** and **BLANCA BEATRIZ ALVAREZ**, Catedra de Anatomia Comparada, Departamento de Biologia, Facultad de Ciencias Exactas y Naturales, Universidad Nacional del Nordeste, 9 de Julio 1449, 3400 Corrientes, Argentina.

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga). USA: NEW MEXICO: Otero Co: White Sands National Monument, 0.8 km NW of headquarters (DOR). 16 April 1988. T. L. Brown and J. N. Stuart. University of New Mexico Museum of Southwestern Biology (MSB 53336). Torrance Co: 5.3 km S of Estancia (DOR). 3 August 1986. M. A. Williamson. MSB 51881. Both verified by C. W. Painter. First records for counties and for the Tularosa and Estancia closed basins, respectively (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xx + 431 pp.).

Submitted by **JAMES N. STUART**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA; and **TED L. BROWN**, Vector Control Program, New Mexico Environment Department, 525 Camino de Los Marquez, Santa Fe, New Mexico 87502, USA.

STENORRHINA DEGENHARDTII (Degenhardt's Scorpion-eating Snake). BELIZE: CAYO: "Cuxta Bani," upper Raspaculo River, Maya Mountains (88°47'30"W, 16°48'45"N), elev. 440 m. 12 January 1991. P. J. Stafford. Verified by Jonathan A. Campbell. Photographed and released; color slides deposited at The Natural History Museum (BMNH), London (NHM Photo Ref. Nos. T11851–T11855). Originally published in error as *Stenorrhina freminvillii* (Stafford 1991, Bull. British Herpetol. Soc. 38:10–17). New snake for Belize, extending range northeast ca. 120 km from the Sierra de Santa Cruz highlands of east-central Guatemala.

Submitted by **PETER J. STAFFORD**, Department of Botany, The Natural History Museum, Cromwell Road, London SW7 5BD, United Kingdom.

TANTILLA NIGRICEPS (Plains Black-Headed Snake). USA: TEXAS: Roberts Co: 17.70 km (by road) NW jct Tex. Rt. 283 and Tex. Rt. 282 on Tex. Rt. 283 (ca. 19.95 road km NW Miami), 35°49'41"N, 100°47'38"W, 890.0 m elev. 18 May 1996. T. J. LaDuc, D. I. Lannutt, and J. D. Johnson. Verified by C. S. Lieb. UTEP 16284. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **DOMINIC I. LANNUTTI** and **TRAVIS J. LADUC**, Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998, and Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

TANTILLA OOLITICA (Rim Rock Crowned Snake). USA: FLORIDA: Monroe Co: Vaca Key, City of Marathon, under board on Aviation Boulevard. 13 April 1996. John Decker. Verified by David L. Auth. Florida Museum of Natural History (UF Photograph 103789). Island range extension beyond Grassy Key, except for questionable Key West specimen.

Submitted by **KENNETH L. KRYSKO**, Wildlife Ecology and Conservation, University of Florida, Gainesville, Florida 32608, USA, and **JOHN DECKER**, 5926 Thomas St. #18, Hollywood, Florida 33021, USA.

THAMNODYNASTES CHAQUENSIS (Chaco Coastal House Snake). PARAGUAY: ÑEEMBUCU: 5 km E Pilar City (26°52'S, 58°23'W), 15 September 1992, A. R. Giraudo and V. Riveros. 26 March 1993. Verified by Sara Bergna. Herpetological collection of PROBBAS, Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Corrientes, Argentina (CFA 87, adult female; CFA 381, adult male). First record for Paraguay. Species was recently described by Bergna and Alvarez (1993, Facena 10:8–15) and was only known from north of Santa Fé province and east of Formosa and Chaco provinces.

Submitted by **ALEJANDRO R. GIRAUDO**, Becario de CONICET, Instituto Nacional de Limnologia, José Maciá 1933, 3016, Santo Tomé, Santa Fe, Argentina.

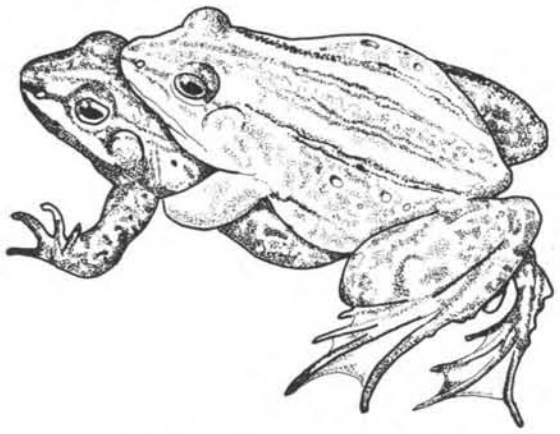
THAMNOPHIS CYRTOPSIS CRYTOPSIS (Blackneck Garter Snake) USA: COLORADO: Otero Co: ca. 100 m E County Rt. 109, 1.5 mi S jct. David Canyon Road. 29 May 1996. Verified by Hobart M. Smith and David Chiszar. UNC-MNH Photograph 14. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.).

Submitted by **SCOTT BOBACK, CHAD MONTGOMERY, JUSTIN HOBERT, ENOCH BERGMAN, BEN HILL** and **STEPHEN P. MACKESSY,** Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

THAMNOPHIS CYRTOPSIS CYRTOPSIS (Western Blackneck Garter Snake). USA: COLORADO: Otero Co: 0.5 km S Mile Marker 41, Rt. 109, 15.5 km N Bent County line, 1300 m. 21 July 1996. Bryon Shipley, Clint Henke and Tim Morris. Verified by Richard L. Holland. UCM 57799. First preserved specimen (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc. 22 pp.).

Submitted by **BRYON SHIPLEY, CLINT HENKE** and **TOM MORRIS**, Department of Herpetology, Denver Zoo, City Park, 2300 Steele Street, Denver, Colorado 80205-4899, USA; and **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

THAMNOPHIS MARCIANUS MARCIANUS (Checkered Garter Snake). USA: TEXAS: Hansford Co: 5.95 km (by road) W Spearman on Tex. Rt. 759, 36°11'55"N, 101°08'06"W, 940.9 m elev. 19 May 1996. T. J. LaDuc. Verified by R. G. Webb. UTEP 16272. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).



Submitted by **DOMINIC I. LANNUTTI** and **TRAVIS J. LADUC**, Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998, and Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

THAMNOPHIS PROXIMUS (Western Ribbon Snake). USA: TEXAS: Hardeman Co: 14.5 km E Quanah, Rt. 1167. 30 September 1995. Janelda E. Chavez. WTAMU 15008. Verified by Anthony I. Mazeroll. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press. 434 pp.).

New Records of Reptiles from the State of Paraná, Brazil

JULIO CESAR DE MOURA-LEITE
and
SÉRGIO AUGUSTO ABRAHÃO MORATO
Museu de História Natural Capão da Imbuia
Departamento de Zoológico, Prefeitura Municipal de Curitiba
R. Prof. Benedito Conceição, 407
82810-080, Curitiba, Paraná, Brazil

and
RENATO SILVEIRA BÉRNILS
Alameda Santos, 2384, apt. 52
01418-200, São Paulo, São Paulo, Brazil

Bibliographical data on the herpetofauna from the state of Paraná, Brazil, are scarce. Besides the species lists of Boettger (1905) and Bérnils and Moura-Leite (1990), data are available only from systematic revisions of genera and/or groups of species. However, previous herpetological collections fail to have significant samples of reptiles from Paraná. During the last thirteen years, a detailed survey on the herpetofauna of the Paraná has been conducted by us, resulting in significant enhancement of distributional maps for several species. All records are based on specimens deposited in the herpetological collection of the Museu de História Natural Capão da Imbuia (MHNCI) at Curitiba, State of Paraná. Identifications of snakes, lizards, and turtles were verified by Marcos Di Bernardo (Museu de Ciencias e Tecnologia, Pontifícia Universidade Católica do Rio Grande do Sul), and the amphisbaenid by José Duarte de Barros Fiho (Universidade Federal do Rio de Janeiro).

TESTUDINES

Phrynops williamsi (Williams' Side-necked Turtle). Capitão Leônidas Marques Municipality: Iguaçu River. 26 March 1993. E. S. Grando, Jr. and A. P. Barreto. MHNCI 6095; Nova Prata do Iguaçu Municipality: Salto Caxias, Iguaçu River. January 1991. S. Zamith. MHNCI 3923, MHNCI 4432; Pinhão Municipality: Segredo Power Plant, Iguaçu River. August 1987. M. V. Segalla. MHNCI 3121.

AMPHISBAENIA

Cercolophia robertii (NCN). Campo Mourão Municipality. 1990. Collector unknown. MHNCI 3473.

LACERTILIA

Ameiva ameiva (Green Ameiva). Centenário do Sul Municipality: Taquaruçu Power Plant, Paranapanema River. February 1992. L. A. Silva. MHNCI 4985; Lupionópolis Municipality. 21 April 1989. L. A. Silva. MHNCI 2912; Santa Inês Municipality. 10 May 1992. L. A. Silva. MHNCI 4987.

Pantodactylus quadrilineatus (NCN). Arapoti Municipality. August 1990. S. A. A. Morato. MHNCI 3355; Jaguariaíva Municipality. September 1990. S. A. A. Morato. MHNCI 3401.

Teius oculatus (Green Lizard). Jaguariaíva Municipality: Chapada de Santo Antônio. 3 May 1991. J. T. W. Motta. MHNCI 4103; Ponta Grossa Municipality: 25 October 1990. F. Iung. MHNCI 3422.

Tropidurus itambere (Rock Lizard). Arapoti Municipality: Perdizes River. 30 June 1991. S. A. A. Morato and R. S. Bérnils. MHNCI 4115, MHNCI 4116; Jaguariaíva Municipality: Pesqueiro. 18 October 1986. S. Larocca and F. C. Zanella. MHNCI 1350; Tibagi Municipality: Guartelá. 13 February 1994. M. C. Córdova. MHNCI 6560.

SERPENTES

Apostolepis dimidiata (NCN). Arapoti Municipality: Fábrica de Papel. March 1991. M. B. M. Rocha and S. A. A. Morato. MHNCI 3950. Campo Mourão Municipality. January 1993. P. H. Labiak. MHNCI 6009; Centenário do Sul Municipality. 15 July 1991. L. A. Silva. MHNCI 2528; July 1989. L. A. Silva. MHNCI 3086; 15 December 1992. V. A. Morais and L. A. Silva. MHNCI 5891; Colombo Municipality. 1992. Collector unknown. MHNCI 6459; Jaguariaíva Municipality. 1989. Collector unknown. MHNCI 2746; Lupionópolis Municipality. 1989. Collector unknown. MHNCI 2915.

Atractus maculatus (NCN). Campo Largo Municipality: Três Córregos. 1991. Collector unknown. MHNCI 4818.

Atractus taeniatus (NCN). Apucarana Municipality. October 1987. Collector unknown. MHNCI 2108, MHNCI 2123; Cascavel Municipality. 1990. J. Gomes. MHNCI 4850; Francisco Beltrão Municipality. April 1986. Collector unknown. MHNCI 501; Pato Branco Municipality: Bairro Brasília. 15 February 1988. S. Bedin. MHNCI 2274; Pinhão Municipality: Reserva. 28 September 1991. E. Grando, Jr. MHNCI 5012; Pinhão Municipality: Jordão River. 24 November 1991. F. C. Straube, B. L. Reinert and F. Zanella. MHNCI 5090; Santo Antônio do Sudoeste Municipality. 11 October 1994. Collector unknown. MHNCI 7007, MHNCI 7008.

Chironius flavolineatus (Liana Snake). Arapoti Municipality. March 1991. Collector unknown. MHNCI 4110; Jaguariaíva Municipality. 1989. Collector unknown. MHNCI 2741, MHNCI 3347; Palmeira Municipality: Santa Rita Farm. 5 May 1985. F. C. Straube and F. A. Sedor. MHNCI 204; Palmeira Municipality: Witmarsum. 5.VI.1991. Collector unknown. MHNCI 4446; Ponta Grossa Municipality: Alagados. 25 July 1991. F. Iung. MHNCI 4567; Ponta Grossa Municipality: Vila Velha. 29 March 1984. R. S. Bérnils. MHNCI 719; Porto Amazonas Municipality: PR 427 Road. 15 September 1984. K. N. Suzuki. MHNCI 3456.

Chironius multiventris (Liana Snake). Guaraqueçaba Municipality: Superagui Island, Barranco Branco. 30 April 1993. D. R. Vianna and W. Nicolack. MHNCI 6160; Guaraqueçaba Municipality: Tagaçaba. August 1993. P Scherer-Neto. MHNCI 6381; Guaratuba Municipality: Arraias. November 1956. W. Martins. MHNCI 454; Morretes Municipality. March 1989. E. Brandão. MHNCI 2572.

Ditaxodon taeniatus (NCN). Ponta Grossa Municipality: Vila Velha. 20 October 1992. F. Iung, H. Garcia and R. Oliveira. MHNCI 5827; 5 December 1992. F. Iung and L. Daru. MHNCI 5924.

Eunectes notaeus (Yellow Anaconda). Foz do Iguaçu Municipality: Itaipu Power Plant, Paraná River. 1992. Sent from Itaipu Binacional. MHNCI 2434.

Hydrodynastes gigas (Big Flat Snake). Guaíra Municipality: Paraná River. November 1987. Sent from Itaipu Binacional. MHNCI 2777.

Imantodes cenchoa (Blunthead Tree Snake). Guaraqueçaba Municipality: Tagaçaba. June 1985. D. Schause. MHNCI 1015; Piraquara Municipality: Volta Grande. 1983. R. J. Hertel. MHNCI 243.

Leptodeira annulata (Banded Cat-eyed Snake). Astorga Municipality. 21 May 1991. Collector unknown. MHNCI 4317.

Leptophis ahaetulla (Parrot Snake). Foz do Iguaçu: Itaipu. 17 September 1986. A. R. Neves, Jr. MHNCI 3871; Guaíra Municipality: Sete Quedas. October 1982. J. J. Bigarella. MHNCI 632, MHNCI 633; Nova Prata do Iguaçu Municipality: Salto Caxias. 11 February 1988. I. V. Schwartz. MHNCI 2246.

Liophis meridionalis (NCN). Lapa Municipality. 12 November 1986. R. Vergennes. MHNCI 1451; Ponta Grossa Municipality: Vila Velha. 27 March 1984. J. C. Moura-Leite and J. T. Motta. MHNCI 707; 8 May 1993. D. Schiesinsky and M. Staveski. MHNCI 6368.

Phalotris tricolor (NCN). Centenário do Sul Municipality. December 1991. L. A. Silva. MHNCI 4876.

Pseudoboa nigra (NCN) Apucarana Municipality. 1994. G. C. Machado. MHNCI 7370.

Rhachidelus brazili (Black Snake). Astorga Municipality: Bairro Itaipu. 25 May 1990. Collector unknown. MHNCI 3488. Cruzeiro do Oeste Municipality. June 1986. M. F. Santos. MHNCI 446; Maringá Municipality. February 1987. Collector unknown. MHNCI 2734; Toledo Municipality. 1 February 1993. Collector unknown. MHNCI 6000; 16 March 1994. Collector unknown. MHNCI 6639.

Simophis rhinostoma (False Coral Snake). Campo Largo Municipality. 1990. Collector unknown. MHNCI 3359; Sengés Municipality. January 1988. C. S. Macedo. MHNCI 2342.

Distribution of *Nerodia taxispilota* and *Nerodia rhombifer* in Alabama, USA

ALLEN L. GOSSER*
LEE F. KENNAMER
and
JAMES L. DOBIE
Department of Zoology and Wildlife Science
Auburn University, Auburn, Alabama 36849–5414, USA

**Present Address: Department of Fisheries and Wildlife, Utah State University, Logan, Utah 84322-5210, USA*

Nerodia taxispilota
(Brown Water Snake)

ESCAMBIA COUNTY: An individual *Nerodia taxispilota* was observed by JLD and Dent Williams in 1992 adjacent to a tributary of Little River in Claude D. Kelly State Park (CDKSP), 3.1 km S of Uriah (not on the boundary between Monroe and Baldwin counties as indicated by Mount [1975, Reptiles and Amphibians of Alabama. Publ. Alabama Agr. Exp. Sta., Auburn, 347 pp.]). Two other specimens (AUM 33645 and 33647) were collected at base of Little River Lake spillway in CDKSP in 1993 and 1994.

COUNTY LINE BETWEEN MONROE AND BALDWIN COUNTIES: Three specimens (AUM 33682, 33683 and 33690) were found in Little River between Benack Bridge (located S of Mineola on an unmarked, paved county road) and Chrysler Bridge (located S of Chrysler on Ala. Rt. 59) in 1993 and 1994. Searches for *N. taxispilota* at the confluence of Little River and the Alabama River west of Tensaw in Baldwin yielded no specimens. A snake from Mt. Vernon, a locality within the Mobile Bay drainage in Mobile County, was considered by Halton (1931, Alabama Geol. Surv. Nat. Hist. Mus. Pap. 11:1–145) to be "in every way an intermediate between *rhombifera* and *taxispilota*." The identity of that snake cannot be determined because the number of dorsal scale rows was 31, a figure within the range of dorsal scale row counts for both *N. taxispilota* and *N. rhombifer* (Mount 1975, *op. cit.*).

Nerodia rhombifer
(Diamondback Water Snake)

Although no *Nerodia rhombifer* were seen in CDKSP, in Little River, or in the Alabama River west of Tensaw, this species does occur in the Mobile Bay drainage as indicated by Mount and Schwaner (1970, Herpetologica 26:76-82) and as depicted on maps in Mount (1975, *op. cit.*) and Conant and Collins (1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 450 pp). The presence of *N. taxispilota* and *N. rhombifer* in the Mobile Bay drainage indicates the probable sympatry of the two species. Topographic maps show that some tributaries of the Mobile and Peridido River drainages (the latter also contains *N. taxispilota*) are separated by a distance of less than one km. During periods of high water, *N. taxispilota* could have migrated from a tributary of the Perdido River into one of the Mobile Bay drainage.

The identity of the AUM specimens was verified by Craig Guyer.

New Distributional Records of Reptiles from Western and Trans-Pecos Texas, USA

TROY D. HIBBITTS
and
MARLA P. HIBBITTS
Biology Department, University of Texas at Arlington, Box 19498
Arlington, Texas 76019, USA

and
TOBY J. HIBBITTS
610 Hilltop Circle, Wylie, Texas 75098, USA

The herpetofauna of western and Trans-Pecos Texas is well documented for most species (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, Texas. 434 pp), making new distributional records for this region scarce and significant.

In this note, we list nine new county records for western and Trans-Pecos Texas, filling distributional gaps for six species and documenting range extensions for three species of reptiles (Dixon 1987, *op. cit.*). These specimens were collected by or donated to the authors during Summer field work between 1993 and 1995. Verification of specimen identification was by Jonathan A. Campbell.

LACERTILIA

Eumeces multivirgatus (Many-lined Skink). CROCKETT CO: ca. 10 km SSE of Barnhart. April 1994. UTA-R 36889. Specimen provides further documentation of a southwestern Texas plains population previously known from neighboring Reagan, Irion, and Pecos counties.

Hemidactylus turcicus (Mediterranean Gecko). TERRELL CO: Sanderson. 5 June 1994. UTA-R 36893. Fills distributional gap between Pecos, Brewster, and Val Verde counties. *H. turcicus* should be expected in most of the towns of the Trans-Pecos.

Scincella lateralis (Ground Skink). TERRELL CO: ca. 30 km S of Sheffield, Chandler Ranch. March 1993. UTA-R 36888. Second record from county west of the Pecos River. Specimen was collected in an isolated pocket of oaks along Independence Creek.

SERPENTES

Coluber constrictor (Racer). BREWSTER CO: 18.9 km S of Alpine on Tex. Rt. 118. July 1993. UTA-R 36887. First record for Brewster County, extending the range of this species in the Davis Mountains highlands of the Trans-Pecos southeast ca. 50 km from the vicinity of Davis Mountains State Park. Specimen has eight infralabials, characteristic of the subspecies *C. c. oaxaca* and *C. c. mormon*.

Crotalus viridis (Western Rattlesnake). REAGAN CO: 2.4 km S jct Farm Road 2600 on Farm Road 33. 2 June 1994. UTA-R 36891. Fills distributional gap along the southeastern edge of the species range in Texas.

Heterodon platirhinos (Eastern Hognose Snake). MENARD CO: 6.6 km S jct Farm Road 1773 on US Hwy 83. 13 May 1995. UTA-R 38345. New county record from the western edge of the species distribution in West-Central Texas.

Lampropeltis getula (Common Kingsnake). REAGAN CO: 10.1 km S jct. Farm Road 33 on Tex. Rt. 137. 2 June 1994. UTA-R 36892. New county record.

Lampropeltis triangulum (Milk Snake). CROCKETT CO: ca. 16 km SE of Barnhart; captive hatched from gravid female collected at above location on 16 May 1994. UTA-R 38339. New county record, apparently an intergrade between the subspecies *L. t. annulata* and *L. t. celaenops*.

Leptotyphlops dulcis (Texas Blind Snake). CROCKETT CO: 6 km SE of Barnhart. May 1994. UTA-R 36890. New county record.

Acknowledgments.—We thank David Gibson and Brian Box for collecting assistance. We also thank John Davis for the donation of the *Scincella* specimen. Funding for travel expenses was provided in part from a grant from the University of Texas at Arlington chapter of Phi Sigma.

County Records for Reptiles and Amphibians in Missouri Found in the Vertebrate Museum at Southeast Missouri State University

RICK ESSNER
and
A. J. HENDERSHOTT
Southeast Missouri State University
One University Plaza
Cape Girardeau, Missouri 63701, USA

The county records listed below are based on maps appearing in Johnson (1987, The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City. 368 pp.) and subsequent records published in the Missouri Herpetological Association Newsletters. All specimens were verified by John Scheibe except where noted.

Hyla chrysoscelis/Hyla versicolor (Gray Treefrog). BUTLER CO: Sec. 15, T26N, R7E. 11 August 1994. Rick Essner. SEMO 211. MADISON CO: Sec. 18, T32N, R6E. 6 October 1995. Neal Young. SEMO 441.

Chrysemys picta (Painted Turtle). PERRY CO: Beihle, Sec. 18, T34N, R11E. 16 September 1995. Rick Essner. SEMO 465.

Sceloporus undulatus hyacinthinus (Northern Fence Lizard). MADISON CO: Sec. 18, T32N, R6E. 8 October 1995. Neal Young. SEMO 440.

Lampropeltis getula holbrooki (Speckled Kingsnake). MADISON CO: St. Francis River at Rt. E bridge. Sec. 18, T32N, R6E. 6 October 1995. Neal Young. SEMO 439.

Opheodrys aestivus (Rough Green Snake). CAPE GIRARDEAU CO: Sec. 32, T31N, R14E. July 1993. John Scheibe. Verified by Ronald A. Brandon. SEMO 291.

Virginia valeriae elegans (Western Earth Snake). BUTLER CO: Wapapello Training Site, Sec. 15, T26N, R7E. 20 July 1995. R. Essner and A. J. Hendershott. SEMO 426.

BOOK REVIEWS

Frogs, by David Badger, photography by John Netherton. 1995. Voyageur Press, Stillwater, Minnesota. 144 pp. Hardcover. US $29.95. ISBN 0-89658-233-7.

RONALD ALTIG
Department of Biological Sciences, Mississippi State University
Mississippi State, Mississippi 39762, USA
e-mail: rga2@Ra.MsState.edu

I am excited by the notoriety that frogs enjoy, but I am amazed at the number of books produced without apparent regard for "doing something differently." Even though current research produces some snazzy results that would make great popular prose, the author, with a continual string of quotations that I found aggravating, often follows the paths of Carr, Cochran, Dickerson, Goin, Oliver, Mertens, and others. These folks made great contributions, but the information is old, and an informed lay-person, for whom the book was written, needs newer, less redundant information. Promotion of current research and the people who do that work would have been much more valuable. It takes immense talent and knowledge to render scientific terminology into regular English (I still debate whether this art can be learned), and few persons have the ability to do this and still maintain accuracy. Examples include: frogs secrete mucus (not mucous); I do not believe the United States imports eatable frogs from New Zealand (unless they are cultured bullfrogs and therefore let us be accurate); I find it unlikely that *Mantella* (Madagascar) avoids predation by mimicking dendrobatids (Neotropics); cold-blooded is an old and inaccurate term; and no frog is buxom from my viewpoint. The apparent attempt to illustrate the impact that frogs have had on literary writings and the reason for attempting this did not work well in my readings of the book.

The photographs, their reproduction, and the general construction of the book are quite good, but I must badger the author and Voyageur Press just a little bit—*Agalychnis callidryas* is a handsome frog, but every object I see, including the month of December 1995 on my wall calendar and eight times, counting the cover, in this book seems to sport this frog. If the blue seduction of *Dendrobates azureus* also can be avoided, I would prefer really

knockout photographs of frogs of an evidently lesser kind. Also, I have no aversion to well-staged photographs, but *Eleutherodactylus planirostris* is never going to encounter a Venus-fly trap without human help. A frog that hangs from a limb by its armpit probably is not a happy fellow, and I do not want to see multiple versions of the same photographs in the same book, even if one of them (a floating *Bombina* photographed from the bottom) offers a unique view. Featuring four photographs of a *Leptopelis* (Old World hyperoliid) within the account of a *Centrolenella* (= old name; one photo; New World centrolenid) gives an incorrect suggestion of their relatedness among "glass frogs" and emphasizes the dangers of common names. Conversely, with the large influx of non-herpetologists into the sampling arena because of the declining amphibian dilemma, it has been argued that common names may have a better utility (i.e., they do not change when the generic or species names are changed) than systematic nomenclature, but it seems to me that this author also generated new common names. The de novo generation of the name *vulvosa* (I think for *favosa*, a synonym) sounds a little too Freudian.

Maybe I should not review anything just before final exams! The readable text and the many, high-quality color illustrations in this book will serve the very basic neophyte rather well. After discussion of general subjects, 50 species from around the world are treated in more detail. It just bothered me that the book falls among a crowd when it could have stood upright as a singular model with more work and even a quick outside review before the press was turned on.

The Dangerous Snakes of Africa—Natural History; Species Directory; Venoms and Snakebite, by Stephen Spawls and Bill Branch. 1995. Ralph Curtis Books, P.O. Box 183, Sanibel Island, Florida 33957, USA. 192 pp., 120 color photos, 93 maps. Hardcover. US $39.95.

JOHN E. SIMMONS
Natural History Museum, University of Kansas

e-mail: jsimmons@kuhub.cc.ukans.edu

Approximately 90 of the 400 species of snakes in Africa are venomous. Of these, only about 30 species are known to have fatal bites. However, a considerable number of deaths from snakebite occur each year on the continent. The "official figure" of approximately 4000 deaths per year is thought to be a gross underestimate—the authors of this volume believe the actual total to be much higher.

The intended audience for this book is the general reader and members of the medical community who need to identify dangerous snakes and cope with snakebite. The text thus provides a mixture of snake natural history and information about venoms and the treatment of bites. Nevertheless, this book will be useful to herpetologists who need to identify venomous species and learn more about venoms.

One thing that becomes obvious on reading the text is how little really is known about the natural history of most African snakes. Some accounts are very short, such as *Atractaspis battersbyi*, which is known from only two specimens. The introduction includes a plea to readers to document and publish field observations on African snakes.

Not all of the snakes included in this volume are really dangerous, e.g., *Homoroselaps dorsalis*. This is one of the smallest snakes in Africa, at a maximum length of 300 mm, but it is included because other members of the genus are considered dangerous. Also included is the African rock python (*Python sebae*), which "is non-venomous [but] can grow large enough to inflict a serious bite."

Six pages are devoted to basic instructions on how to identify snakes, and what field information is needed for successful treatment of a venomous snakebite. The distribution of African venomous snakes occupies three pages, and species descriptions take up 130 pages. The species accounts are organized by family. Each section begins with anything from a few sentences describing the worldwide range of the family to more detailed discussions of family level taxonomy (e.g., sea snakes).

Both scientific and common names (in English) are provided for each species. Illustrations include a distribution map and color photo. Sometimes more than one photograph is included to show geographic variation, e.g., the northern and southern variants of *Homoroselaps lacteus*; color phases of *Naja nigricollis*; patterned and patternless *Causus rhombeatus*. The majority of the photos are good to excellent, and most show the snakes on natural backgrounds. A few photographs are of preserved specimens. There are drawings of head shapes and body patterns where appropriate.

The information in the section on identification varies from one account to another, but may include size, colors, and scale counts. Some descriptions are quite detailed. Distinguishing characteristics are given to help confirm the identity of the particular species. Brief descriptions of subspecies (referred to in the text as "races"), with notes on distribution, are provided as appropriate. Notes on the distinguishing characteristics of similar species found in Africa are also included.

Behavioral information includes when the species is active, when bites are most likely to occur, and notes on aggressive behavior. The known distribution of each species is outlined, and one or more range maps are provided for each account. Habitat and natural history information, when available, are briefly summarized, including diet, reproduction, and relative abundance.

The section on venoms and bites includes total venom yield (if known), toxicity, and a brief review of symptoms and progression of envenomation. Published case histories of bites are cited. The section on treatment of bites varies quite a bit from one account to another. It includes information on the availability of anti-venom and recommended first aid and medical procedures. For some snakebites, treatment recommendations are fairly minimal (concerned mostly with infection); for more dangerous snakes, detailed clinical procedures are presented.

There is an extensive section on snakebite (22 pages). It begins with a discussion of snakebite occurrence in Africa, followed by more detailed descriptions by region (North, Southern, Central, and West Africa). There are tips for avoiding snakebite, a discussion of African snake venom types and components, and a section titled "What Happens When a Snake Bites?" with appropriate photographs. The section on treatment of snakebite begins with a list of nine things not to do when confronting this emergency. The use of a pressure bandage is recommended, in contrast to current procedures for North American venomous snakebites. The terms *anti-serum* and *anti-venom* are used synonymously. Most of this section is directed towards physicians needing guidance on the medical treatment of snakebite. It includes diagnosis, when to administer anti-venom, and how to administer it. A table of available anti-venoms with addresses of suppliers is provided, as well as a section on "Use of Anti-serum by a Layperson." This includes what to carry by way of a field kit and how to determine whether or not to administer anti-venom.

Appendix I is a checklist of dangerous African snakes, with occurrence indicated in seven geographic regions. Species are listed on the checklist only by their common English name, rather than by scientific name. Appendix II is a list of "Institutions Dealing with African Snakes." This curious compilation lists only 18 zoos, museums, and universities worldwide. Only one institution (California Academy of Sciences) is listed for the U.S. There is also a list of six doctors "with a particular interest in African snakebite," again with just one entry (Findlay Russell) for the United States. It is not clear why this appendix is so short. If expanded, it would be much more useful.

The bibliography on African snakebite runs just over five pages (mostly case histories). A bit over one page is devoted to the topic of "Further Reading on African Snakes," a reflection of just how few books there are on this topic. The glossary runs three pages, and contains simple, easy-to-understand definitions of the medical terms used in the snakebite treatment sections.

Given that the intended audience for this book is non-herpetologists and medical workers, it still contains a lot of information useful to anyone interested in African snakes. The color photographs, distribution maps and notes, and information on venoms make it a worthwhile reference. The species accounts are well-designed for ready information retrieval, and the text is crisp and clear throughout. Although I found myself wishing that references to the natural history and systematics of the snakes were included, given the primary audience for which this book is designed, the authors have done an excellent job of compiling a large amount of needed information in a very readable and attractive book.

Amphibian Biology, Volume 2: Social Behavior, edited by Harold Heatwole and Brian Sullivan. 1995. Surrey Beatty & Sons Pty, Ltd., xi + 419–710 pp. (pagination continued from Volume 1). Hardcover. AUS $75.00 (approx. US $60.00). ISBN 0-949324-60-4.

Amphibian Biology is a five-part series reviewing physiological and evolutionary topics in amphibian biology. Intended as a companion to *Biology of the Reptilia*, the series aspires to be the most authoritative source of information on amphibians available. Volume Two covers the social behavior of amphibians and includes seven chapters, ranging from the very broad, empirically rich topics of female choice and mating system structure in amphibians, to the more specific analysis of aggression and territoriality in salamanders.

Chapter One, by Tim Halliday and Miguel Tejedo, examines intrasexual selection and alternative mating behaviors in urodeles and anurans. The authors stress that the evolution of sex-related characters cannot be understood purely through the study of sexual interactions, but must embrace life history and physiological variables as well. This important point is exemplified in a section on sexual dimorphism, in which the interactions between factors other than competitive behavior are examined. Most of the sections in this chapter provide comprehensive theoretical and empirical reviews. I found the theoretical review of alternative mating strategies incomplete, however, as it barely mentions the contributions of game theory. In addition, portions of this chapter are difficult to read due to the use of terms that are not clearly defined. Overall, however, this chapter provides an excellent review of an extensive field.

Chapter Two, by Brian Sullivan, Michael Ryan, and Paul Verrell, also reviews a broad field: the empirical and theoretical literature of female choice and mating system structure. The authors highlight the role that amphibians have played in demonstrating female choice, and point out the limitations of using amphibians to test predictions of the different models for the evolution of female preference. Their review of mating system structure follows the traditional ecological classification system (Emlen and Oring 1977), which they suggest facilitates comparison with prior work. It is curious, however, that studies that consider variability in female behavior, which are now prevalent in the ornithological literature, either do not exist or were not reviewed here.

Chapter Three, by Martha Crump, reviews parental care in amphibians. The review of the empirical literature in this chapter is impressive, and includes an extensive table in the appendix which summarizes the modes of parental care within Amphibia. The evolution of parental care is examined from both historical and adaptive perspectives, and although I felt that the theoretical review was comprehensive, I was surprised by the lack of studies that have examined the evolution of parental behaviors in a phylogenetic context (although see Weygoldt 1987).

Chapter Four, by Andrew Blaustein and Susan Walls, is titled "Aggregation and Kin Recognition." This chapter sets out to cover abiotic and biotic factors that influence associations among amphibians, but focuses most of its attention on the mechanisms and potential benefits of kin recognition. In Chapter Five, Carl Gerhardt and Joshua Schwartz examine behavioral and acoustic interactions between species that reduce the efficiency of intraspecific communication as well as the potential effects of hybridization on the evolution of homogamy. Their review of hybrid zones and hybridization between broadly sympatric species suggests that studies of anurans will continue to play an exciting role in unraveling the mechanisms of speciation. Chapter Six presents a detailed description of territoriality in a few species of salamanders, compared to territoriality in frogs. While it appears that much more data are needed to determine the extent of territoriality in salamanders, Alicia Mathis and colleagues present enough intriguing examples to suggest that studies of this ecologically diverse group could provide valuable insights into the evolution of territoriality. Finally, in Chapter Seven, Lynne Houck and Sarah Woodley examine the physiological mechanisms that underlie reproductive behaviors. They do an excellent job of putting the limited data (16 species) into a theoretical perspective. The intriguing case in which corticosterone levels increase without depressing androgen levels, possibly tied to explosive and highly opportunistic mating bouts (Orchinik et al. 1988), highlights the exciting possibilities for future work in this area.

On a mundane note, I had three complaints concerning editing and production of the book. First, the subject index is very limited and thus not very useful, which is an unfortunate shortcoming for a review series. Second, the format used to delineate the various subcategories within the text (different fonts) is confusing once you reach the third sublevel. And finally, the quality of the black and white photographs is not the best, which is really too bad as some of the shots (such as direct developing young emerging from dorsal pouch in *Gastrotheca ovifera*) are spectacular.

In summary, this book is likely to be the best current source of information on amphibian social behavior. Although not as comprehensive as the behavioral volume in *Biology of the Reptilia*, the reviews of the subjects covered in this book are for the most

part complete. Most of the chapters do a good job of presenting the empirical literature within current theoretical context. Many of the chapters suggest interesting directions for future studies, which should be very valuable for graduate students initiating research projects using amphibians. However, only a few of the chapters mention, and even then indirectly, the need for studies that address the evolution of amphibian social behavior in a phylogenetic context. Studies of the social behavior of many organisms are now being considered in this context, and yet the lack of these kinds of studies throughout all of the chapters (with the exception of work by Ryan et al. 1990, Ryan and Rand 1993a and b discussed in Chapter Two) was quite striking. This is not a criticism of the book so much as a comment on the field of amphibian biology. This volume is dedicated to Kent Wells, who has made numerous contributions to the study of behavioral ecology of amphibians, including the now classic 1977 paper "The Social Behaviour of Anuran Amphibians" in *Animal Behaviour*. In this paper, Wells pointed out patterns of similarity in the social behavior of anurans from widely divergent families and suggested a need for an evolutionary framework for understanding the relationship between social behavior and ecology in anurans. It is obvious from the literature cited in this book that some aspects of the social behavior of anurans have now been studied extensively. And yet, with all of the intriguing variation these works have uncovered, the hypotheses that Wells set forth in 1977 in relation to patterns of reproduction, mate-acquisition tactics, and modes of male-male competition, remain untested in a phylogenetic context.

e-mail: kka4@cornell.edu

Why does the Amazon Basin support greater terrestrial biodiversity than any other comparable area? Is it explained by the dynamic cycles of dominance by savanna and rain forest communities that have continued to alternate at least since the beginning of the Quaternary Period? Is it the result of the middle Miocene Amazon Sea which divided the continent into three separate land areas, from which the present fauna is now derived? These, among other questions, continue to fascinate tropical biologists who will welcome Teresa C. S. Ávila-Pires' extraordinary compendium as an exemplar of the very sort of basic information needed to resolve these and other fundamental questions. The book was published by the Nationaal Natuurhistorisch Museum in Leiden, under the editorship of Marinus S. Hoogmoed.

Lizards are the best known reptiles in Amazonia, yet knowledge of their systematics, distribution, and ecology is still fragmentary for most species. Ávila-Pires, a former staff member at the Museu Paraense Emílio Goeldi in Belém, near the mouth of the Amazon River, has produced an exhaustive monograph of the 89 species of lizards (in 40 genera and nine families) found in Brazilian Amazonia, a region primarily of tropical rain forest that covers about one fourth of the entire continent. Two of these species are actually species complexes, each composed of both bisexual and parthenogenetic forms. The account for each species includes a synonymy, a full list of specimens examined (with localities, museum records, collectors, and dates of collection), a diagnosis, a detailed description (with drawings of the head and feet, often from several views), coloration, habitat, natural history (ecology, behavior, feeding habits, and reproduction), distribution (with spot map, including the range outside of Amazonia, if any), and remarks on taxonomy, geographic variation, questionable earlier records, etc. There is a key to species, an extensive discussion of zoogeography, and a 19-page bibliography. Finally, there are 100 color photographs depicting 76 species, some of them illustrated in color for the first time. The materials on which this book is based were drawn from 35 museums, including all of the relevant collections throughout the world, but one. Regrettably, the authorities of the Museu de Zoologia da Universidade de São Paulo refused access to its extensive collection. This is a disservice to science.

Six new species (*Stenocercus fimbriatus, Lepidoblepharis hoogmoedi, Leposoma osvaldoi, L. snethlageae, Tretioscincus oriximinensis, Tupinambis longilineus*) and one new subspecies (*Anolis nitens tandai*) are described in this book. Several taxonomic changes are made, one of which is of particular interest because it involves the names of two well-known species that are common in the commercial trade. Ávila-Pires shows that the taxa long known as *Tupinambus nigropunctatus* and *T. teguixin* instead should be called *T. teguixin* and *T. merianae*, respectively. The most common skink in Amazonia, until now referred to as *Mabuya bistriata,* should be called *M. nigropunctata*, and the former name replaces *M. ficta*. The zoogeographic analysis of species distributions, using Rosen's Parsimony Analysis of Endemicity method, supports the division of Amazonia into eastern and western faunas as well as the recognition of southwestern and Guianan groups, but rejects the hypothesis that Amazonia was covered with a continuous savanna during recent times.

The errors in the key (page 21), between couplets 59 and 62, have been noted on an inserted errata slip in the first printing (940 copies), but have been corrected in the second printing (514 copies), together with some typographical errors in the text. Contrary to rumor, the book is still in print.

From my point of view there are very few deficiencies. Nowhere is Brazilian Amazonia exactly defined or mapped. For a book of this size, there is surprisingly little cross indexing, making it inconvenient to move from one section of the book to another (for example, from the key or color photographs to the relevant text description) without consulting the index. There are relatively few misspellings, omissions, or other errors (a missing piece in

the bibliography inadvertently has Merrem mixed up with Mertens). The color photographs are uneven in quality, as might be expected since most were taken in the field, but several of them should have been lightened in printing to reveal additional details of scutellation. Representatives of three genera are depicted in black and white only, and there is no photograph at all of the monotypic *Amapasaurus tetradactylus*; a photograph of a preserved specimen would have been of some value since this species is unknown to most herpetologists.

Despite these minor imperfections, Ávila-Pires' book is a major contribution to our knowledge of Neotropical lizards and, in turn, to our understanding of Amazonian biodiversity. This book will be the standard on the topic for many years to come, and against which hoped-for volumes on the other groups of Amazonian herpetofauna will be compared. It is a high standard indeed.

Reptiles of Washington and Oregon, edited by Robert M. Storm and William P. Leonard, with contributions by Herbert A. Brown, R. Bruce Bury, David M. Darda, Lowell V. Diller, Charles R. Peterson, and Robert M. Storm. 1995. Published by the Seattle Audubon Society, Trailside Series. Hard and soft cover. i–xiii + 176 pp. ISBN 0-914516-12-4. US $16.95 (soft cover).

RONALD A. NUSSBAUM
Division or Reptiles and Amphibians, Museum of Zoology
The University of Michigan, Ann Arbor, Michigan 48109-1079, USA
e-mail: nuss@umich.edu

This attractive field guide, appropriately dedicated to the memory of Murray L. Johnson, is a companion volume to the Audubon guide to the "Amphibians of Washington and Oregon" published in 1993. The format is much the same as the amphibian volume, with the same amount of detail in the species accounts, and with equally high quality illustrations.

After the Table of Contents, publisher's Preface, Introduction, and Acknowledgment, the book begins with a checklist of the reptiles of Washington and Oregon (one notes the curious non-alphabetical order of state names in the title, checklist, and elsewhere). The checklist emphasizes common names, and uses the names suggested in Circular No. 19, published in 1990 by the Society for the Study of Amphibians and Reptiles. Prior to the species accounts, there are brief sections on an "Overview of Reptiles," "Notes on Turtles," "Notes on Lizards," and "Notes on Snakes" which parallel the order of the subsequent species accounts. The intention of the book, stated in the first sentence of the Introduction, is to "help teachers, students, naturalists, professional field biologists and lay-persons to identify the reptiles of Washington and Oregon" (again, state chauvinism is evident). In this, the book surely succeeds without question.

Nomenclature follows the "most recent and widely accepted common and scientific names," and binomials are followed by the name, or names, of the author(s) who described the species. In this respect, the guide is more accurate than the preceding amphibian guide, wherein "Good" is credited with describing a salamander that was described by Baird and Girard. The list of reptiles for the two states is up-to-date and differs from the previous list presented by Nussbaum et al. (1983) only in that the name for the Oregon form of the aquatic garter snake has changed from *Thamnophis couchi* to *T. atratus* and *Pituophis melanoleucus* has reverted to *P. catenifer*. Neither of these changes is proposed in the field guide, but instead follow the suggestions of cited authors. The former change is probably warranted, but the latter was done without supporting data and may or may not be justified. Other taxonomic changes proposed in the recent literature, e.g., elevating *Coluber constrictor mormon* to species rank, were not accepted.

Although the species names used are current, recent changes in supraspecific nomenclature are not always followed. For example, the various iguanian species are listed under the family "Iguanidae," in contrast to the revision of Frost and Etheridge (1989). It it unclear whether this was done because of disagreement or ignorance of the literature. For the intended audience, it will make little difference.

In general, the overview and notes sections on reptiles, turtles, lizards, and snakes are accurate and provide condensed and useful information. The section on turtle notes, perhaps because of the paucity of native species, concentrates on introduced species and draws on information regarding species that do not occur in the two states covered by the book. Remarks about the historical biogeography of turtles in the Pacific Northwest are unsupported and perhaps counterintuitive. One unfortunate aspect of the "notes" sections is the suggestion that particular groups are more-or-less adapted than are other groups..."lizards have better adaptations for living on land than salamanders" (p. 14)...a viewpoint that does not survive logical analysis.

Another problem with the overviews presented in the book is undocumented assertions. For example (p. 15): "fall can be a stressful time for hatchlings [lizards] hibernating for the first time, and this age group often suffers high mortality during the winter." One wonders what is "stressful" for a lizard and where are the data that prove winter mortality is higher for hatchlings than for older lizards. Similarly, it is inaccurate to suggest that courtship and reproduction in snakes involves combat when this form of male-male aggression has never been documented for most species of snakes, and clearly does not exist in many species. Garter snakes are among the most commonly encountered snakes in Oregon and Washington, and there is no evidence that male-male aggression is part of the mating system of that group of species. These few criticisms are, however, not very serious when balanced against the overall high quality of the volume.

The species accounts include sections on "Description," "Similar Species," "Distribution" (accompanied with a small range map with state and county boundaries showing the distribution in shading), "Habits and Habitat," and "Remarks." The descriptions are brief and include the critical identifying characteristics in bold print. For the most part, these descriptions, always on the left facing page, are accurate, and, along with the color photographs on the right facing page, will easily facilitate species identification. Subspecies are addressed in the "Remarks," including information on their identification and distribution. Geographic ranges of subspecies are not included on the distribution maps.

The other sections in the species accounts are brief and to the point. Most useful in these sections are comments about the current population status and legal protection of various species. Notes on life history and ecology are for the most part correct, but here again there are some instances of unwarranted statements and assumptions. For example, the statement that male side-blotched lizards are territorial is unsubstantiated for northern populations, and there is evidence that their social system may be one of dominance hierarchies rather than territoriality (Nussbaum and Diller 1976).

The color photographs in the book are spectacular, and they alone are worth the price of the book. One could quibble about background representation: *Gambelia wislizenii* (p. 61) and *Phrynosoma douglassii* (p. 66) are not likely to be encountered on rocks, but the artistic license is not really distracting, and the photos are always relevant.

Following the species accounts is a table contrasting the characteristics of garter snakes in the two states and three figures illustrating characteristics of certain groups of reptiles. These are followed by a list of general references and a selected bibliography. A glossary of important terms and county maps of "Washington and Oregon" end the book.

This is a welcome addition to the literature on the herpetofauna of the Pacific Northwest. The editors, contributors, and publishers are to be congratulated for producing this compact and useful book.

Phylogenetic Systematics of Crotaphytid Lizards (Reptilia: Iguania: Crotaphytidae), by Jimmy A. McGuire. 1996. Bulletin of Carnegie Museum of Natural History, No. 32. 143 pp. 52 figures (including 12 color photographs). US $27.50 plus $1.50 shipping and handling ($2.00 for non-U.S. addresses). Available from Carnegie Museum of Natural History, Office of Scientific Publications, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213-4080, USA.

This revision of the collared and leopard lizards combines data sets from osteology, squamation, allozymes, soft tissues, color pattern, life history, and behavior. McGuire recognizes 12 extant species and confirms the monophyly of *Crotaphytus* and *Gambelia*. Taxonomic accounts and dot distribution maps are presented for each species.

Amphibians of Oregon, Washington and British Columbia: A Field Identification Guide, by Charlotte C. Corkran and Chris Thoms. 1996. Lone Tree Publishing. Softcover, 175 pp. US $16.95 (CDN $21.95). ISBN 1-55105-073-0. Available from the publisher in Canada (#206, 10426 81st Avenue, Edmonton, Alberta, Canada T6E 1X5) or the U.S. (16149 Redmond Way, #180, Redmond, Washington 98052, USA).

As the title suggests, this small book emphasizes field identification. This is accomplished by numerous color photographs of larval and adult amphibians and their egg masses. Illustrated identification keys are presented for eggs (for both western and eastern portions of the book's coverage area), hatchling salamanders, larval and metamorphosed salamanders, hatchling and larger tadpoles, and adult frogs and toads. A table compares features of species likely to be confused with others; this is accompanied by color photographs that depict important field markings. Suggestions for finding and observing amphibians in the field, including seasonal considerations, are offered. Instructions for conducting field surveys are also presented.

Biology and Conservation of Sea Turtles, revised edition, edited by Karen A. Bjorndal. Smithsonian Institution Press, Washington. 1995. Paperback. 615 pp. ISBN 1-56098-619-0. US $29.95 + $3.25 postage and handling.

This comprehensive overview of sea turtle biology, based on the contributions to a 1979 conference, was first published in 1982. The revised edition incorporates all of the original 64 chapters plus a short (45 pages) section on recent advances in sea turtle biology and conservation. The latter is divided into 14 contributions, each serving to encapsulate recent results in active areas of sea turtle research. Although not exhaustive, these additional chapters cite the pertinent recent literature and present a perspective on the field 16 years after the original contributions were first presented.

Venomous Snakes of North America (videocassette), written and narrated by Scott Shupe. 1996. Natural History Educational Co., P.O. Box 469, Cadiz, Kentucky 42211, USA. Tel. (502) 924-9107. 30 minutes. US $24.95.

Presumably intended for elementary through high school students, this educational video concentrates on venomous snakes of the southeastern United States: eastern diamondback and canebrake rattlesnakes, water moccasin, copperhead, etc. Informative narration accompanies video footage of snakes in their natural environment.

Atlas of Amphibians in Tennessee, by William H. Redmond and A. Floyd Scott. Miscellaneous Publication No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA. 1996. Softcover (spiral bound), 94 pp. ISBN 1-880617-05-6. US $8.00 (include. shipping and handling).

An up-to-date account of the distribution, taxonomy, and known habitat requirements of the 21 species of frogs and 45 species of salamanders occurring in Tennessee, featuring dot distribution maps for each taxon. Also included are short sections dealing with the history of herpetology in Tennessee, the physiography, climate, soils, drainage, vegetation, and ecological regions of the state, and questionable and erroneous reports of amphibians from Tennessee. An extensive literature cited section and comprehensive index to scientific and common names follow the text and maps.

Bibliographie der Gürtelechsen und Schildechsen (Reptilia: Sauria: Cordylidae & Gerrhosauridae) [Bibliography of the Girdled Lizards and Plated Lizards], by Klaus Adolphs. Squamata Verlag, Pastor-Hochhard-Str. 8, D-53757 Sankt Augustin, Germany. 1996. Softcover, 255 pp. ISBN 3-9805086-0-9. DM 39,80 (approx. US $27.00) + postage.

An extensive bibliography of the Cordylidae and Gerrhosauridae covering the period from 1758 to 1995. More than 1000 references are cited, each with an annotation as to the taxa discussed and the topics covered. Also included are a current classification/checklist of girdled and plated lizards and an index to the authors cited by taxon.

Statement of Ownership, Management and Circulation

(Required by 39 U.S.C. 3685)

1A. Title of Publication	1B. PUBLICATION NO.	2. Date of Filing
HERPETOLOGICAL REVIEW	0 0 1 8 0 8 4 X	9-25-96

3. Frequency of Issue	3A. No. of Issues Published Annually	3B. Annual Subscription Price
QUARTERLY	4	$24--subscription $40--membership

4. Complete Mailing Address of Known Office of Publication *(Street, City, County, State and ZIP+4 Code) (Not printers)*

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST; e-mail: ejohnson@ptdprolog.net).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at 303 West 39th Street, Hays, Kansas 67601-1518, USA. Periodicals postage is paid at Hays, Kansas with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, P.O. Box 626, Hays, Kansas 67601-0626. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

For back orders only: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA (fax 314-977-3658). E-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1997 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Telephone: Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July (Theodore Pietsch, Chair).
1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).

1997 Annual Meeting
Society for the Study of Amphibians and Reptiles
40th Annual Meeting
together with
American Society of Ichthyologists and Herpetologists
and
The Herpetologists' League
26 June – 2 July 1997
University of Washington, Seattle, Washington, USA

The University of Washington in Seattle (the "Emerald City"), situated in the verdant Pacific Northwest, will host the combined annual meetings of SSAR, HL, and ASIH. The Greater Seattle area is considered one of the most beautiful in the United States, and offers residents and visitors alike nearly unparalleled access to a variety of social, recreational, and outdoor activities.

Keynote Address: The keynote address will be given by Martha Crump, HL's Distinguished Herpetologist for 1997.

Symposium: "NUCLEAR DNA AND THE EVOLUTIONARY GENETICS OF FISHES, AMPHIBIANS AND REPTILES." *Organizer*: Andrew M. Shedlock, University of Washington, FTR, Box 355100, Seattle, Washington 98195, USA; e-mail: shedlock@u.washington.edu.

Symposium: "ECOLOGICAL PROCESSES: INSIGHTS FROM FIELD EXPERIMENTS AND NATURAL HISTORY." This symposium celebrates the career and contributions of Margaret McBride Stewart in honor of her 70th birthday. *Organizer:* Kiisa C. Nishikawa, Department of Biological Sciences, Northern Arizona University, Flagstaff, Arizona 86011-5640, USA; e-mail: Kiisa.Nishikawa@nau.edu.

Symposium: "COMPARISONS AND CURRENT USES OF PHYLOGENETIC APPROACHES TO ICHTHYOLOGY AND HERPETOLOGY." *Organizers*: Mark Pyron, Illinois Natural History Survey, Center for Biodiversity, 607 East Peabody Drive, Champaign, Illinois 61820, USA; e-mail: Pyron@uiuc.edu. Robert E. Espinoza, Department of Biology, University of Nevada, Reno, Nevada 89557-0015, USA; e-mail: espin_r@unr.edu.

Photo by Brian Walsh.

Symposium: "THE CHEMICAL ECOLOGY OF PREDATOR/PREY RELATIONSHIPS: FISHES, AMPHIBIANS, AND REPTILES." *Organizers*: Alicia Mathis, Department of Biology, Southwest Missouri State University, Springfield, Missouri 65804-0095, USA; e-mail: sam477f@vma.smsu.edu; Debra Lancaster, Department of Biology, Whatcom Community College, Bellingham, Washington 98226, USA. Brian Wisenden, CEEB, T. H. Morgan School of Biological Sciences, University of Kentucky, Lexington, Kentucky 40506, USA; e-mail: brian@CEEB.uky.edu.

Workshop: "NOMENCLATURE FOR NOVICES." *Organizer:* Carl J. Ferraris, Jr., Department of Ichthyology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118, USA; e-mail: ferraris@cas.calacademy.org.

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day in or near the University of Washington's Husky Union Building. Poster sessions will be held at the HUB.

Student Paper Awards: Seibert Prizes will be awarded to the two best student-presented papers at the meeting ($300 first prize, $200 second prize).

The tailed frog (*Ascaphus truei*), a Pacific Northwest endemic, is the only member of the ancient family Ascaphidae. This species should be encountered on the Mt. Saint Helens field trip. Specimen from Ellis Creek, Pacific Co., Washington. Photo by William Leonard.

Multimedia Presentations: "HERPS OF THE WEST" and "AMPHIBIANS OF THE APPALACHIANS" by David Dennis and Eric Juterbock; "HERPETOLOGICAL NAMESAKES" by Kraig Adler and David Dennis.

Social Activities: General Reception at Seattle Aquarium, Auction, Salmon Barbecue, Graduate Student Reception, Banquet.

Live Exhibit: Live herps of the Pacific Northwest, sponsored by the Society for Northwestern Vertebrate Biology and the Pacific Northwest Amphibian and Reptile Consortium. As usual, a diverse array of animals will be available for viewing and photography.

Symposium: "LIFE HISTORY AND ECOLOGY OF CHELONIANS." *Organizers*: R. Bruce Bury, National Biological Service, 3080 SE Clearwater Driver, Corvallis, Oregon 97333, USA; e-mail: buryb@mail.cor.epa.gov; and David J. Germano, Department of Biology, California State University Bakersfield, 9001 Stockdale Highway, Bakersfield, California 93311-1099, USA; e-mail: dgermano@academic.csubak.edu.

Workshop: "PRESERVATION AND CURATION OF EARLY LIFE HISTORY STAGES OF FISHES, AMPHIBIANS, AND REPTILES." *Organizers:* Alexandra M. Snyder, MSB Division of Fishes, University of New Mexico, Albuquerque, New Mexico 87131-1091, USA; e-mail: amsnyder@unm.edu; and Darrel E. Snyder, Larval Fish Laboratory, Colorado State University, Fort Collins, Colorado 80523, USA; e-mail: desnyder@picea.cnr.colostate.edu.

Vendors: Books, carvings, jewelry, t-shirts, and equipment of interest to herpetologists.

Field Trips: ***Mount Saint Helens National Volcanic Monument*** (led by Charlie Crisafulli) to examine recovery of amphibian populations since the 1981 volcanic eruption. This trip will provide an opportunity to see salamanders and frogs in one of the most fascinating landscapes found anywhere in the Pacific Northwest. The ***Snoqualmie Pass–Ellensburg*** field trip will be led by Herb Brown and Bill Leonard. It will begin in the shrub-steppe habitats near Ellensburg to search for reptiles and then work back towards Seattle, stopping in Ponderosa pine forests and at the summit of Snoqualmie Pass. Field trip cost $15/person. Address questions about field trips to Bill Leonard (e-mail: bpmm490@wadnr.gov).

Venue: All paper and poster sessions will be held at the University of Washington campus.

Costs: Pre-registration $120 regular, $60 student, $60 accompanying person. After March 15, costs are $145 regular, $75 student, and $75 accompanying person.

Accommodations: 800 dorm rooms have been reserved for the meetings. A six-night package, including breakfast and lunch (all you can eat!) is available for $224 per person (double occupancy) or $296 per person (single). A list of nearby hotels and motels is available on the meeting Web page (see below) or by contacting Dikmen Travel.

Student Travel Grants: Ten travel grants of $200 each will be available for SSAR student members. Refer to details elsewhere in this issue of *HR*.

Travel Arrangements: The official travel agency for the 1997 meetings is Dikmen Travel, Inc., 1127 Pine Street, Suite 150, Seattle, Washington 98101, USA. Tel. (206) 447-9535, ext. 309 or (800) 234-5636; fax (206) 628-3509; e-mail: fdikmen@webtravel.com. The recommended airport is Sea-Tac Airport, ca. 15 miles south of the UW campus in Seattle. Shuttle service to area hotels and the University is available at the airport from Super Shuttle.

Family Activities: Seattle offers many family activities near UW, including visits to the UW Burke Museum, Seattle Aquarium, Woodland Park Zoo, and the Pike Place Market. Downtown Seattle offers a wide variety of shopping opportunities. Also available are ferry rides out of the Port of Seattle.

Climate: The campus of the University of Washington lies close to sea level. Summer days are usually in the upper 60s to lower 70s F and dry, but nights can be expected to drop to about 60 F. While western Washington usually experiences a summer drought, some rainfall in late June and early July would not be unusual.

Collecting Permits: Scientific collection permits are required for taking of all amphibians and reptiles in Washington. Requests and/or questions should be sent well in advance of the meeting to: *Steve Dauma, Enforcement Division, Washington Department of Fish and Wildlife, 600 Capitol Way North, Olympia, Washington 98501-1091, USA*.

Further Details: Contact T. W. Pietsch, School of Fisheries, University of Washington, Box 355100, Seattle, Washington 98195-5100, USA. Tel. (206) 543-8923; e-mail: twp@fish.washington.edu. Meeting Announcement and Call for Papers will be mailed to all U.S., Mexican, and Canadian members of SSAR in late November 1996. Other persons wishing to receive this information may do so by contacting Ted Pietsch at the address above. A World Wide Web page devoted to meeting information may be found at: http://artedi.fish.washington.edu/asih/asih97.html.

Plethodon vandykei (Van Dyke's salamander) is a seep- or stream-dwelling plethodontid restricted to three areas of Washington. Specimen from Mt. Saint Helens, Washington. Photo by William Leonard.

SSAR BUSINESS

1996 Annual Meeting: Lawrence, Kansas

The 39th annual meeting of SSAR occurred from 24–29 July, 1996 in Lawrence, Kansas. The University of Kansas, with Linda Trueb chairing the local committee, served as host to 398 attendees. Most of the meeting's events took place in the Kansas Union and the Natural History Museum.

The unofficial opening of the meetings, the annual meeting of the SSAR Board of Directors, took place on 24 July between 1005–1755 h. Unfinished business forced the Board to reconvene on 26 July from 1210–1320 h. In attendance for most of the Board meeting were Elected Officers: Lou Guillette, Henry Mushinsky, Karen Toepfer, Ellen Censky, Paul Moler, Jim Bogart, Don Forester, Jan Caldwell, Al Savitzky, Lyndon Ardell Mitchell; Appointed Officers and Editors: Bob Aldridge, Rich Seigel, Bob Powell, Joe Collins, Kraig Adler, Tom Tyning, Stephen Corn; Committee Chairs and Coordinators: George Pisani, Marty Crump; Members: Tom Fritts, Eric Juterbock, Douglas Taylor. Others attended to make presentations throughout the day. A summary of business conducted was presented at the Business Meeting (see below).

Presentations

The meetings officially began at 0900 h on 25 July in the Woodruff Auditorium with opening remarks and announcements from Linda Trueb. She introduced SSAR President Lou Guillette who called the meetings to order and announced the initiation of a "mentoring" program which was implemented at these meetings and consisted of informal student-mentor lunches. The next to take the podium was Leonard Krishtalka, Director of the Natural History Museum, University of Kansas, who welcomed SSAR members to the University. Zybnek Rocek was then introduced. He provided a preview for prospective attendees of the Third World Congress of Herpetology in Prague in 1997. He also announced that he had registration packets for the Prague meeting and these would be available throughout the meetings. The final address at the morning session was the Plenary address given by Michael J. Tyler (University of Adelaide, Australia) and entitled "New drugs from old frog skins."

A total of 191 presentations were made in 13 sessions and 3 symposia between 1300 h on 25 July and 1130 h on 29 July. The symposia were "A Tropical Natural History: Essays in Honor of William E. Duellman," "Diversity of Approaches to Amphibian and Reptilian Systematics," and "Population Status and Conservation of Amphibians." In addition, a workshop on Herpetological Collections: Funding, Growth, and Management was conducted along with tours of the new fluid collections facilities on 29 July. The Conservation Forum: Point-Counterpoint— "Relocation, Repatriation, and Translocation: Viable Options or Halfway Technologies"— was also held the morning of 29 July.

Immediate Past-President Al Savitzky called to order the 39th Annual Business Meeting of the SSAR at 1532 h on Monday, 29 July, in Alderson Auditorium of the Kansas Union. He noted first that since he was filling in for President Guillette, and Immediate Past-Secretary Eric Juterbock was filling in for Secretary Censky, it should be clear to everyone that the coup had been successful!

Savitzky relayed several items from President Guillette. Mentor lunches were established for this meeting; senior herpetologists made themselves available for lunch with students who signed up in advance. Although organized after we had gotten to Lawrence, these were very successful. Marty Crump reported at the Board Meeting for the Committee on International Cooperation, and suggested that SSAR should become significantly involved in same. Other business that Savitzky reported included: the SSAR Board approved $4000 for student travel to the Third World Congress in Prague, August 1997, as well as being part of the three-society grant application to NSF for additional funds; and, the Board is supporting the development of a booklet listing grants and awards available to herpetologists, this being compiled by Joan Milam.

The timing of the Business Meeting required that Juterbock report for many of the officers. The Society is in fine financial shape (see report elsewhere), and the Board approved a 1997 budget of $183,050. The *Journal of Herpetology* reports record submissions, with the down side being an increase in the lag time, a problem that the Board is addressing. *Herpetological Review* also faces the same situation; it and the *Catalogue of American Amphibians and Reptiles* have had some editorial changes during the year. *Contributions to Herpetology* will publish "Gecko Fauna of the USSR and Contiguous Regions," by N. N. Szczerbak and M. L. Golubev, in December 1996, and "Biology of the Reptilia, v. 19," edited by C. Gans and A. Gaunt, and "Lizards of Iran," by S. C. Anderson, in 1997. *Facsimile Reprints in Herpetology* will publish Stejneger's "Herpetology of Japan" in 1996 and Fitzinger's "Neue Classification der Reptilien" in 1997. *Herpetological Circulars* will publish No. 25, "Standard Common and Current Scientific Names for North American Amphibians and Reptiles, 4th edition" and No. 26, "Lineages of Zoo Herpetologists in the United States," by W. Card and J. B. Murphy, during the next year. In early 1997, *Herpetological Conservation* will issue No. 1, "Amphibians in Decline," edited by D. Green.

The Conservation Committee is investigating the production of a conservation brochure; Chair Ken Dodd asked that suggestions regarding content should be sent to him. Grants-in-Herpetology and the Kennedy Award are announced elsewhere, as are the Resolutions, which were read by John Moriarty; the resolutions were adopted unanimously by the membership. David Auth noted that the Seibert Award competition was extremely competitive this year; there were 31 students entered (see announcement below). The Student Travel Committee awarded three $200 travel awards this year; their silent auction of materials from 20 donors netted $1922.

Nominations for election to SSAR office for 1997 were announced. President-elect: Darrel Frost and Justin Congdon; Secretary: Ellen J. Censky; Treasurer: Robert Aldridge; Director (Class of 1999): David Sever and Wayne Van Devender; Director (Regional Societies): Dale Belcher, Charles W. Painter and John Moriarty.

Social Program

Special events and social programs were numerous and well-attended. The welcoming social, held in the Kansas Union Ballroom on the evening of the 24th took on special significance as it honored some of our premier herpetologists: Roger Conant, Henry S. Fitch, Hobart M. Smith, Robert C. Stebbins, and Ernest E. Williams. Conant, Fitch, and Smith were in attendance. The rain held off and the weather cooled down for the SSAR barbeque which was held at Clinton Lake on Friday, 26 July. Students were treated to a social on Saturday which featured not only snacks and beverages, but also a reprint scavenge.

The SSAR Student Travel Awards Auction, with scheduled viewing and silent bidding for one day only, on the fifth floor of the Kansas Union, was extended for a second day. This activity,

organized and conducted solely by students, has proven to be a very successful endeavor at raising money for student travel to meetings. Also on the fifth floor, The Jayhawk Room housed the numerous exhibitors and vendors selling books, t-shirts, art work, and research equipment, among other things. A Herpetological Art Exhibit was displayed throughout the meetings in the Kansas Union Gallery. A prize of $100.00 was presented to Dale Johnson as best entry for her drawing of a marbled salamander. The live animal exhibit, prepared by members of the Kansas Herpetological Society, featured herps of the region and provided photo opportunities between Saturday and Monday. "Snakes in Kansas," another live exhibit, was also available for daily viewing in the Natural History Museum.

For the bibliophiles in the crowd, a special book exhibit opened to coincide with the SSAR Meeting. The spectacular exhibit, entitled *"Slithy toves: Herpetological Books in Kansas"* (Department of Special Collections in the Spencer Research Library), displayed about 80 illustrated books spanning five centuries (16th–19th centuries). In addition, a roundtable on Herpetological Book Collecting was held. This special discussion group included Kraig Adler, Aaron Bauer, Adrian Crane, Ronald Javitch, Ernie Liner, and Richard Wahlgren, and convened to offer advice to those interested in book collecting.

The traditional events, the SSAR Auction and the Multimedia Presentation, were not a disappointment. The Auction, with many items donated and long-time auctioneer Joe Collins at the helm, progressed into the wee hours of the night and raised over $4,000.00. Later in the week, a full house viewed the multimedia presentations: "Herps of the West" and "Amphibians of the Appalachians" by David Dennis and Eric Juterbock, and "Namesakes of North American Amphibians and Reptiles" by Kraig Adler and David Dennis. Other slide shows included "Exotic Places, Exotic Herps," an event organized by graduate students to provide an opportunity to share their field experiences with fellow students, and the SSAR President's Travelogue, which featured presentations by William Lamar and Lou Guillette.

Some members were able to partake in tours of the Fitch Natural History Reservation on 29 July and received the special treat of being guided by Henry Fitch and George Pisani.

—Respectfully submitted by Ellen J. Censky, SSAR Secretary, and J. Eric Juterbock.

About Our Cover: *Phrynohyas resinifictrix*

Among the frogs of the family Hylidae, *Phrynohyas resinifictrix* is one of only three species known to utilize water-filled tree cavities for egg deposition and development. The genus *Phrynohyas*, described by Fitzinger in 1843, includes five species of robust anurans ranging collectively from northern México to Argentina. The species *P. resinifictrix* was only recently re-discovered, having long been thought to be conspecific with the ubiquitous and well-known *P. venulosa*. Like its congeners, *P. resinifictrix* is large (up to 76 mm), and bears a thick, probably toxic, glandular skin festooned with big, rounded tubercles.

A denizen of the great equatorial forests from French Guiana and Brazil westward to Colombia, Ecuador, and Peru, this impressive amphibian seems to occur in low densities, perhaps a single male per several hectares. Seldom descending to the ground from the tree cavities in which they live and breed (is it a glider?), this species may produce in excess of 1000 eggs at a time. The male's honking, barklike call, one to three notes long, is amplified by its tree hole. Typically, finding this frog requires a painstaking nocturnal stalk, a considerable climb, and insertion of the hand or arm into the stagnant, murky ooze in which these creatures live.

The specimen on the cover is an adult male, seen *in situ* as it emerged from its lair near the Ucayali River, Department of Loreto, Peru. It was photographed in late afternoon, using available light with a Pentax LX 35mm camera, 20mm lens, and Fujichrome Velvia film. The photographer is **William W. Lamar**, Adjunct Professor of Biology at the University of Texas in Tyler. A connoisseur of remote rainforests, Lamar has spent over twenty years in the neotropics. He worked for many years on Colombian crocodilians and turtles with renowned authority Federico Medem. Author of numerous herpetological publications, and co-author (with Jon Campbell) of the immensely popular book, *The Venomous Reptiles of Latin America*, Bill is a Research Associate at two of our best museums: The Collection of Vertebrates at the University of Texas at Arlington, and the Natural History Museum at the University of Kansas. Currently involved in long-range projects in Peru and Costa Rica, Lamar, with colleagues George Gorman and George Ledvina, also runs GreenTracks, Inc., an ecotour company providing natural history trips to the tropics for both specialists and the general public.

Separation and imaging of Lamar's photograph is the work of **Jim Bridges** of Herpeto Inc., Hollywood, Florida, USA.

1996 SSAR Resolutions

Honoring Outgoing SSAR Officers and Editors

WHEREAS the following individuals have given freely of their time, skills, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year; and,

WHEREAS they have been therefore instrumental in advancing the Society's goals and furthering its growth as an international scientific society; and,

WHEREAS SSAR is dependent upon the generosity of these persons and those who have gone before them, and is greatly indebted to them for their fine efforts in its behalf;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles urges these persons not to ride off into the sunset, but rather to continue to be available, with or without official titles, as resources to guide those who follow; and,

RESOLVED FURTHER that the Society offers its most sincere thanks to the following persons who have served in these capacities:

WAYNE VAN DEVENDER—CAAR Section Editor and Chair, 1995 Local Committee
ALAN H. SAVITZKY—President
DAVID M. GREEN—Director
GREGORY K. PREGILL—Director
STEVE REILLY—Chair, 1995 Nominating Committee
ROBIN ANDREWS—Member, 1995 Nominating Committee
STEVEN BEAUPRE—Member, 1995 Nominating Committee
WILLEM ROOSENBURG—Member, 1995 Nominating Committee

RALPH AXTELL—*Herpetological Review* Section Editor
HENRY MUSHINSKY—*Journal of Herpetology* Associate Editor
JIM PETRANKA—*Journal of Herpetology* Associate Editor

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 29 July 1996 at its Annual Business Meeting.

Thanking The Local Committee

WHEREAS a majority of the people at the Meeting were products of, or influenced by, the KU Herpetology Program; and,

WHEREAS some of those people still seem to be on speaking terms with their mentor, who successfully assembled them for a group mug shot; and,

WHEREAS the quaint alcohol regulations of the Kansas Union tested the adaptive ability of the Society's talented members to define a new optimal foraging strategy at the auction; and,

WHEREAS the selection of dormitory and paper sites has done much to improve the cardiovascular fitness and test the critical thermal maximum of participants; and,

WHEREAS the lack of firmness in dormitory beds has created a new class of herpetologists, hereafter to be referred to as posturally challenged; and,

WHEREAS the opportunity to visit with and benefit from the wisdom and experience of those distinguished herpetologists, who so kindly gave us their time is deeply appreciated; and,

WHEREAS overall this meeting of the Society has been without incident, a tribute both to the organizational skills of the Local Committee and to the advancing placidity of our members,

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles extends its most sincere thanks to the 1996 Local Committee and others whose assistance contributed to the success of this meeting: Linda Trueb (Co-Chair), William E. Duellman (Co-Chair), Patricia Burrowes, Joseph T. Collins, Luis A. Coloma, Cathy Dwigans, Sarah E. Haines, Rafael Joglar, Brad Knauss, John Lee, Anne Maglia, Dan Meinhardt, Joe Mendelson III, Malcolm Neeley, Jeff Parmelee, George Pisani, Jenny Pramuk, Analia Pugener, Eric Rundquist, Nancy Schwarting, Christopher Sheil, Helio da Silva, John Simmons, Amy Sproston, Yuan Wang, Erik Wild, and CellularOne Digital Network.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 29 July 1996 at its Annual Business Meeting.

Honoring Robert Gordon

WHEREAS Robert Gordon was an exceptionally valued friend and mentor to many in the herpetological community; and,

WHEREAS Robert Gordon devoted much time and effort to advancing the goals and stature of the Society for the Study of Amphibians and Reptiles in its formative years; and,

WHEREAS Robert Gordon's death in June 1996 has saddened his many friends and associates;

THEREFORE, be it
RESOLVED that the SSAR hereby expresses its sense of loss of a friend and colleague, and expresses its condolences to the Gordon family.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 29 July 1996 at its Annual Business Meeting.

Herp Art Winners

A Herpetological Art Exhibit was held at the SSAR annual meeting in Lawrence. It was a particularly well-displayed show, with about 30 pieces of art vying for recognition. Judges David Dennis and Kraig Adler announced the following results:

1st Prize ($100)—Dale Johnson, University of Florida; color pencil drawing of a marbled salamander (*Ambystoma opacum*).

Honorable Mentions—Erik Wild, University of Kansas; watercolor drawing of a glass frog (*Centrolene geckoideum*). John Lokke, University of Nebraska at Omaha; series of pencil drawings depicting the decline of the timber rattlesnake (*Crotalus horridus*) in Nebraska.

Kennedy Student Award Committee Annual Report—1996

The Kennedy Award Committee has completed its work for Volume 29 of the *Journal of Herpetology*. The Committee has selected "Ecology and Energetics of Three Sympatric Rattlesnake Species in the Sonoran Desert" by Daniel D. Beck (29:211–223) as the best student-authored paper. Mr. Beck carried out this work as a doctoral candidate in the Department of Ecology and Evolutionary Biology at the University of Arizona. The research was mentored by Charles H. Lowe and was partially supported by the Graduate Student Program Development Fund of the University of Arizona. Daniel Beck currently resides in the Department of Biological Sciences, Central Washington University, Ellensberg, Washington, USA.

Ten manuscripts were in competition this year. The Committee noted the high quality of the submitted papers. Committee members were Robin Andrews (Virginia Polytechnic Institute & State University), David Duvall (Arizona State University), Robert E. Gatten, Jr. (University of North Carolina), Terry D. Schwaner (Southern Utah University), and Ken R. Marion (Chair, University of Alabama at Birmingham).

Seibert Award Winners for 1996 Announced

The fifth annual Seibert Awards were presented at the 39th Annual Meeting of the SSAR in Lawrence. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). The awards recognize outstanding student presentations at the annual meeting. There were 31 presentations eligible.

The winners.—J. R. Mendelson, III (First Award), Natural History Museum and Department of Systematics and Ecology, University of Kansas ("Taxonomy of the Mexican toads referred to *Bufo cavifrons* and *Bufo cristatus*"); Paul T. Andreadis (Second Award–tie), Ecology and Evolutionary Biology, University of Tennessee ("Circadian and lunar influences on feeding activity of

water snakes"); John R. Lee, (Second Award–tie), Department of Zoology, University of Georgia and Savannah River Ecology Laboratory ("Spatial ecology of cottonmouths (*Agkistrodon piscivorus*) in South Carolina: activity ranges, movement rates, and overwintering sites").

Honorable Mention (in no particular order).—M. J. Komoroski, Savannah River Ecology Laboratory ("Relationships of lipids to ovum size in the mole salamander, *Ambystoma talpoideum*"); B. Moon, Department of Biology, University of Michigan ("The effects of different prey movements on the duration and force of constriction by gopher snakes"); G. M. Correa, Departamento de Biologia, Pontificia Universidad Catolica del Ecuador ("Behavior, vocalization and reproductive characteristics of *Colostethus awa* and *C. machalilla* (Anura: Dendrobatidae)").

The judges were Oscar Flores-Villela, co-chair (UNAM), David Auth, co-chair (Florda State Museum, Gainesville), David Chiszar (University of Colorado), Anna Graybeal (University of Texas at Austin), James Dixon (Texas A&M University), Neil Ford (University of Texas at Tyler), Hinrich Kaiser (Universität Würzburg).

Name Guide for Group Photo

Persons who bought the SSAR group photo at the Lawrence meeting may obtain an identification guide by sending a stamped, self-addressed envelope to: *George R. Pisani, Biological Sciences, University of Kansas, Lawrence, Kansas 66045-2106, USA.*

Items Needed for SSAR Auction in Seattle

Joe Collins will be conducting the SSAR auction during the annual meeting at the University of Washington in June 1997. All proceeds from the auction go to the SSAR treasury, and help to continue the production of diverse publications and services for which SSAR is known. Items of value as well as those that lend themselves to humor are always welcome. Joe is skilled at removing large quantities of cash from auction participants through the judicious use of beer and plastic. Auction items may be brought directly to the meeting or sent in advance (clearly marked "Herp Auction") to: *Ted Pietsch, School of Fisheries, 1140 Boat Street, University of Washington, Box 355100, Seattle, Washington 98195-5100, USA.*

SSAR Student Travel Awards Fund-Raiser: 1996 Results and Call For 1997 Donations

The SSAR Student Travel Awards Committee (SSAR STAC) conducted the Third Annual SSAR Student Travel Awards Frameable Art Silent Auction and presented the Second Annual SSAR Student Travel Awards at the SSAR meeting in Lawrence, Kansas. The winners were Laura Monti, Debra Moore, and Rick Owen. Congratulations to all. The SSAR STAC wishes to thank the following for their donations to the Third Annual Frameable Art Silent Auction: Kraig Adler, Robert Aldridge (SSAR), Mark Bailey, Bern and Betty Bechtel, Janalee Caldwell, Joe Collins, David Dennis, Bill Duellman, Stephen Goldberg, Carole Hom, John Jensen, University of Kansas Herpetology Division, Michael J. Lanoo, Ernie Liner, Anne Meylan, Mark and Louise Mills, Ramus Publishing, David Scott, Jeffrey Tamplin, Linda Trueb, Laurie Vitt, and Richard Vogt. The Third Annual Frameable Art Silent Auction raised over $1900 for students attending and presenting papers at the 1997 meeting in Seattle. On behalf of SSAR and the SSAR STAC Chairman, John R. Lee, thanks to all who helped, including Joe Mendelson, Mark Mills, Jeff Demuth, Jenny Pramuk, Susan Lee, and Karen Toepfer. Continuing a successful tradition, the SSAR STAC proudly announces the Fourth Annual Frameable Art Silent Auction to be held at the 1997 SSAR meeting in Seattle. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please contact: *John Lee, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA; tel. 803-725-5873; e-mail: LEE@SREL.EDU.*

SSAR Student Travel Awards Call for Applications

Ten awards of $200 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author (or co-author, see below) of a paper or poster to be presented. An applicant must include in the application package: 1) a letter signed by his/her major advisor or department chair that states: he/she is currently an undergraduate or graduate student and that he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Student Travel Awards Committee are excluded from applying for a travel award. APPLICATIONS MUST BE POSTMARKED BY 15 MAY 1997. Award recipients will be notified by 1 June 1997 and award checks will be disbursed at the meeting. Requests for information on making donations and applications for awards should be sent to: *John Lee, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA; tel. 803-725-5873; e-mail: LEE@SREL.EDU.*

HR's Techniques Editor Resigns

Stephen D. Busack, having served as our first-ever section editor for Techniques during the last two years, has resigned due to the demands of a new position. Effective 1 November 1996, he became Director of Research and Collections at the North Carolina State Museum of Natural Sciences (102 North Salisbury Street, Raleigh, North Carolina 27603, USA). A new museum building, scheduled for opening in late 1999, is under construction at a cost of ca. $31 million. We thank Steve for his service to colleagues and to SSAR, and wish him well in his new position. Authors of techniques manuscripts should send these directly to the editor.

Announcement of SSAR International Cooperation Project (ICP): A Call for Help

Anyone who has carried out herpetological research in a developing country no doubt has felt the frustration expressed by colleagues in that country regarding the inaccessibility of scientific resources. Scientists often are hesitant to publish because they don't have access to the literature—they fear their study may already have been done! Commonplace field supplies such as flagging tape and waterproof paper are either unavailable locally or are too expensive to order from the U.S.

In August 1995, Alan Savitzky, then-President of SSAR, appointed me as Chair of a one-year International Cooperation Committee. Other committee members included Oscar Flores, Tyrone Hayes, and Ted Papenfuss. Our charge was to consider the appropriate nature of international services that could be provided by SSAR. I presented our suggestions to the SSAR Board at the annual meeting in Lawrence, Kansas, on 24 July 1996. Members of the Board were enthusiastic about the ideas, and President Lou Guillette asked if I would coordinate efforts to get an international cooperation program underway. I have agreed to do so, but I need your help.

I propose that, through the International Cooperation Project (ICP), we as a society reach out a collective hand to our international colleagues. The more people involved, the more successful the project will be. Below is a description of various aspects of the proposed project, as we currently envision it, followed by a call for your help. Let's show that SSAR is truly an international society.

ICP Currently Consists of Six Aspects

1. *Internet Service.*—George Pisani (U. Kansas) manages the SSAR web site at http://falcon.cc.ukans.edu/~gpisani/SSAR.html. As part of ICP, George will provide a page on the web site of special interest to non-U.S. herpetologists.

2. *SSAR Grants-In-Herpetology (GIH).*—One grant will be earmarked each year for a non-U.S. applicant from a country where herpetological research historically has been underfunded, and where alternative sources of funding are difficult to secure. Successful proposals must meet the same high standards currently required of all proposals. At the SSAR Board meeting in Lawrence, the Board authorized additional funds for the SSAR Grants-in-Herpetology program.

3. *International Sponsorship.*—As part of ICP, SSAR will establish an International Membership Fund. Donations to the Fund will be used to defray the SSAR membership dues of non-U.S. institutions and/or individuals eligible to apply for GIH funding as above. Donations may be designated as being in support of a particular institution or individual if desired. The SSAR Board has agreed to make ICP-donated international institutional memberships available at the individual amount (currently $40) instead of the usual institution rate (currently $70) as a Society contribution, thus allowing more memberships to be purchased from the Fund. In this way we hope to provide *Journal of Herpetology* and *Herpetological Review* to libraries that otherwise could not afford these publications.

4. *Graduate Program Information.*—Non-U.S. students who wish to come to the U.S. to do graduate study often have difficulty choosing an appropriate institution to match their interests and finding out how to apply. The goal of this aspect of ICP will be to gather information regarding U.S. graduate programs in herpetology (which herpetologists are working at which institutions and where to go for specific emphases), application procedures (e.g., required GRE's and language exams, transcripts, letters of recommendation), and estimated costs of graduate work and potential financial assistance. These materials will be distributed to potential international students and interested institutions.

5. *Funding Source Information.*—All of us are experiencing greater difficulty securing funds for our research as funding agencies have less to offer. Non-U.S. herpetologists often have even greater difficulty securing funds for their research because even less money is committed to research by their own countries. Some U.S. agencies not only are willing to fund research projects submitted by non-U.S. scientists, but actually encourage and prefer such proposals, especially in the field of conservation. The goal of this aspect of ICP will be to write a pamphlet that provides information on how and where non-U.S. researchers can apply for these funds. Availability of this pamphlet will be announced on the SSAR web site and in *Herpetological Review*, and will be distributed to interested persons and institutions.

6. *Preparation of Grant Proposals.*—The SSAR Board authorized an allocation of funds to begin the Committee's work. These funds will be used to pay for postage, long distance phone calls, and faxes associated with organizing the project. In order to expand the project, we need to secure outside funding. Thus, the most time-consuming aspect of ICP at this point will be preparation of grant proposals to be submitted to appropriate agencies and foundations. The project to be included in the first round of proposals involves distribution of donated library materials (journals and reprints) and surplus/gently-used laboratory and field supplies to institutions in Latin America that have expressed need for such items. We plan to initiate the distribution project in Latin America, and later expand to other geographical areas. In the future, proposals may be written to cover expenses for exchange programs and for courses and workshops.

So, How Can You Get Involved?

Every SSAR member is encouraged to become involved in ICP. At this point, the major ways you can help are: 1. Donate to the International Membership Fund, which will provide SSAR memberships to international colleagues and institutions. We will announce details of this program at a later date. 2. Volunteer to coordinate one of the following major projects: a) Graduate Program Information, b) Funding Source Information, c) Distribution Project (library material and supplies)—although this program will not begin until outside funding has been secured, we need to organize the project, d) Preparation of Grant Proposals. The coordinators for these four major projects will join me as members of the ICP committee. 3. Volunteer to help (i.e., work with the coordinator—#2 above) on one or more of the four major activities listed in #2 above.

PLEASE get involved. If you are interested in either helping with or coordinating a major project of ICP, please contact me as soon as possible so that we can form the Committee and begin to work.

NEWSNOTES

Third World Congress of Herpetology 2–10 August 1997, Prague, Czech Republic

The Second Announcement, which includes the Call for Papers and Registration Forms, was published in July and since then, it has been distributed to all respondees to the First Announcement. By the end of September, about 980 persons were preliminarily registered, both neo- and paleoherpetologists, from 71 countries. The Congress will include a rich social program, activities for accompanying persons, 12 possibilities for professional excursions, and three post-Congress tours (including one to Central Asia). The Second Announcement is still available, on request, from the Congress Secretariat (Third World Congress of Herpetology, Congress Secretariat, c/o Czech Medical Association J.E. Purkyne, P.O. Box 88, Sokolovska 31, CZ-120 26, Praha 2, Czech Republic; Fax: ++42-2-24216836; E-mail: LON@CZECHMED.ANET.CZ). Preliminarily registered persons receive the Announcement automatically.

The Congress is open to anybody who works in any field of herpetology or is interested in herpetology. The deadline for submitting abstracts is December 31, 1996 (postmarked). Abstracts sent after this date will be accepted only for poster presentations, but there is no guarantee that they will be included in the printed abstracts or will be distributed to delegates. There are no program limits except that all contributions must present new information.

Message from the Secretary-General

It is time to think about candidates for membership on the Executive Committee and the International Herpetological Committee for the World Congress of Herpetology. Nominations can be advanced either by individuals or affiliated organizations, as appropriate. Our constitution states that "All nominations for membership of these Committees must be received by the Secretary-General at least four months prior to a Congress and must be seconded either by any two members of either the Executive or International Herpetological Committees, or, in the case of the International Herpetological Committee, by the governing body of an Affiliated Organization." I shall be pleased to receive any and all nominations by **MARCH 31, 1997**.

The Travel Subsidy Committee will have many deserving applicants for funding to help defray costs of attending the Congress in Prague. Funds for this purpose are extremely limited, despite efforts to raise additional support. I urge both individuals and societies to consider donating to this important fund. It is to the advantage of all present, and to our science in general, to have as widely representative a body of participants in the Congress as possible. Donations to the Travel Subsidy Fund can be sent to Roger A. Avery, Treasurer, World Congress of Herpetology, Department of Zoology, University of Bristol, Woodland Road, Bristol BS8 1UG, United Kingdom. Thank you!

MARVALEE H. WAKE
Secretary-General, World Congress of Herpetology
Department of Integrative Biology, 3060 VLSB
University of California, Berkeley, California 94720-3140, USA

WCH III Mini-Symposium

As part of the proceedings of the 3rd WCH, the following one-day symposium has been proposed: "Africa—The Neglected Continent: Biodiversity and Biology of the African Herpetofauna." Convenor: *Dr. W. R. Branch, Curator Herpetology, Port Elizabeth Museum, P.O. Box 13147, Humewood 6013, South Africa. Tel. 041 561051; Fax 041 562175; e-mail, pemwrb@zoo.upe.ac.za.*

Africa remains the neglected continent. Containing the majority of the world's poorest countries, indigenous research is severely curtailed by financial constraints, regional conflicts, and a deteriorating infrastructure. Pressure from the burgeoning human population has led to land-use conflicts and has resulted in widespread habitat destruction. The rapid decline of mega-mammals preoccupies world and African conservation bodies, with the consequent neglect of the herpetofauna. The diverse and largely unique herpetofauna remains relatively unknown and unmapped. The aims of the proposed symposium are to: synthesize existing knowledge on the composition, distribution, and biology of the continent's herpetofauna; to identify and prioritize areas and taxa in need of study and conservation; and to stimulate international collaboration between herpetologists and other interested groups.

Anyone interested in participating in this symposium is asked to contact the convenor (address and contact numbers listed above) as soon as possible. Due to limited time, talks should review aspects of relevance to the broad theme of the symposium.

Southwestern Research Station Positions And Grants For 1997

VOLUNTEERS—Approximately 30 volunteer positions are open in 1997 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. Application due date: February 15, 1997. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reservations, answering phones, greeting guests, supervising volunteers, etc. Begin March 15, 1997, through September 1997. Five-day week; salary $210/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. tel. and fax: 520-558-2396.*

Garter Snake Book Correction

Purchasers of *The Garter Snakes: Evolution and Ecology* (University of Oklahoma Press, 1996) by Rossman, Ford, and Seigel, need to be aware of a typesetter's error on page 41 that affects the key. In couplet 3 the first line reads "Maxillary teeth$^3\leq$" and it should read "Maxillary teeth$^3\geq$27"—the number was omitted and the sign reversed. The authors regret the inconvenience, but the error was beyond their control.

Graduate and Post-Graduate Research Grants

The Biological Research Station of the Edmund Niles Huyck Preserve offers grants (max. = $2500) to support biological research which utilizes the resources of the Preserve. Among the research areas supported are basic and applied ecology, animal behavior, systematics, evolution, and conservation. The 2000 acre Preserve is located on the Helderberg Plateau, 30 miles southwest of Albany, New York. Habitats include northeast hardwood-hemlock forests, conifer plantations, old fields, permanent and intermittent streams, 10 and 100 acre lakes, and several waterfalls. Facilities include a wet and dry lab, library, and houses/cabins for researchers. Deadline = 1 February 1997. Application material: *Dr. Richard L. Wyman, Executive Director, E.N. Huyck Preserve and Biological Research Station, P.O. Box 189, Rensselaerville, New York 12147, USA.*

Summer Course on Larval Amphibian Biology at Highlands Biological Station

A course on Larval Amphibian Biology will be taught at Highlands Biological Station June 2–13, 1997. Instructors are Richard Wassersug, Ray Semlitsch, Richard Bruce, and Travis Ryan. This is a lecture, laboratory, and field course addressing a variety of topics on the biology of amphibian larvae. Three semester hours credit at the advanced undergraduate/graduate level is available through either Western Carolina University or the University of North Carolina at Chapel Hill. For further information contact: *Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA. Tel. (704) 526-2602, FAX (704) 526-2797, e-mail: bruce@wcu.edu.*

Kaplan Named U.S. Professor of the Year

SSAR member Robert Kaplan, a professor of biology at Reed College (Portland, Oregon), was selected as a 1996-97 U.S. Professor of the Year by the Carnegie Foundation for the Advancement of Teaching. Kaplan is the first winner from the Pacific Northwest in the history of the national awards program. He was chosen from among nearly 600 nominees from throughout the country. Kaplan received his award, which included a $5,000 cash prize, at a reception in Washington, D.C. on October 10.

Kaplan is well known to herpetologists for his many publications on the developmental biology and ecology of frogs and salamanders. Much of his research is carried out in collaboration with his undergraduate students. In addition to teaching, research, and other professional duties, Kaplan is working with public school teachers to design a hands-on biology curriculum for elementary and middle school students.

SSAR congratulates Bob Kaplan for this singular achievement.

MEETINGS

Meetings Calendar

13–18 January 1997—IUCN Northern Indian Ocean Marine Turtle Workshop, Bhubaneswar, Orissa, India. Contact: Dr. Priyambada Mohanty-Hejmadi, Vice Chancellor, Sambalpur University, JYOTIVIHAR, Sambalpur 768019, Orissa, India (tel. 91-663-430158; fax 91-674-481418) or Dr. Pamela Plotkin, Drexel University, Department of Bioscience & Biotechnology, 32nd and Chestnut Streets, Philadelphia, Pennsylvania 19104, USA (tel. 215-895-1436; fax 215-895-1273; e-mail: Plotkipt@post.drexel.edu).

29–30 January 1997—Federal and International Scientific Permits: A Workshop for Natural History Museums and Collectors. Presented by the San Diego Natural History Museum and co-sponsored by the Association of Systematics Collections. San Diego, California, USA. Contact: Director, Collections Care and Conservation, San Diego Natural History Museum, P.O. Box 1390, San Diego, California 92112, USA; tel. (619) 232-3821, ext. 226; fax (619) 232-0248; e-mail: LIBSDNHM@CLASS.ORG.

24–26 April 1997—Association of Systematics Collections (ASC) Annual Meeting. Atlanta, Georgia, USA. Theme: "The Collections-Based Mission of Natural History Collections." Contact: ASC, 1725 K Street NW, Suite 601, Washington, D.C. 20006-1401, USA; WWW: http://www.ascoll.org/ or e-mail: asc@ascoll.org.

25 June–2 July 1997—40th Annual Meeting, Society for the Study of Amphibians and Reptiles; 45th Annual Meeting of The Herpetologists' League; 77th Annual Meeting, American Society of Ichthyologists and Herpetologists. Hosted by the University of Washington, Seattle, Washington, USA. *Refer to meeting announcement in this issue for details.*

2–10 August 1997—Third World Congress of Herpetology, Prague, Czech Republic. Contact: Zbynek Rocek, Congress Director, Department of Paleontology, Geological Institute, Academy of Sciences, Rozvojová 135, 165 00 Praha 6 – Suchdol, Czech Republic. Tel. (++42-2) 24311421; Fax (++42-2) 24311578; e-mail: rocek@gli.cas.cz. *Refer to meeting announcement in* Herpetological Review *27(1):4–5, March 1996 for details.*

CURRENT RESEARCH

The purpose of **Current Research** is to present basic summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA; e-mail: herpbooks@sisna.com. Comments and suggestions are also welcome.

The current contents of several herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are being listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Advances in Zoo Herpetology

Clay Garrett and David Chiszar recently edited a special issue of *Zoo Biology* which focuses on advances in zoo herpetology.

SCHUETT, G. W. 1996. Fighting dynamics of male copperheads, *Agkistrodon contortrix* (Serpentes, Viperidae): Stress-induced inhibition of sexual behavior in losers. Zoo Biol. 15(3):209–221.

BURGHARDT, G. M., B. WOOD, AND R. ROSSCOE. 1996. Problem of reptile play: environmental enrichment and play behavior in a captive Nile soft-shelled turtle, *Trionyx triunguis*. Zoo Biol. 15(3):223–238.

COOPER, W. E., JR., C. S. DEPERNO, AND S. F. FOX. 1996. Prey chemical discrimination and strike-induced chemosensory searching in lizards: their absence in a crotaphytid lizard (*Crotaphytus collaris*) and a proposal for research in zoos. Zoo Biol. 15(3):239–253.

GARRETT, C. M., et al. 1996. Comparison of chemosensory behavior and prey trail-following in the varanoid lizards *Varanus gouldii* and *Heloderma suspectum*. Zoo Biol. 15(3):255–265.

KARDONG, K. V. 1996. Evolution of aging: theoretical and practical implications from rattlesnakes. Zoo Biol. 15(3):267–277.

FERGUSON, G. W., et al. 1996. Indoor husbandry of the panther chameleon *Chamaeleo [Furcifer] pardalis*: effects of dietary vitamins A and D and ultraviolet irradiation on pathology and life-history traits. Zoo Biol. 15(3):279–299.

REICHLING, S. B., AND W. H. N. GUTZKE. 1996. Phenotypic consequences of incubation environment in the African elapid genus *Aspidelaps*. Zoo Biol. 15(3):301–308.

VALLARINO, O., AND P. J. WELDON. 1996. Reproduction in the yellow-bellied sea snake (*Pelamis platurus*) from Panama: field and laboratory observations. Zoo Biol. 15(3):309–314.

LILLYWHITE, H. B. 1996. Husbandry of the little file snake, *Acrochordus granulatus*. Zoo Biol. 15(3):315–327.

JACOBSON, E. R. 1996. Metabolic scaling of antibiotics in reptiles: basis and limitations. Zoo Biol. 15(3):329–339.

MORRIS, P. J., L. A. JACKINTELL, AND A. C. ALBERTS. 1996. Predicting the gender of subadult Komodo dragons (*Varanus komodoensis*) using two-dimensional ultrasound imaging and plasma testosterone concentration. Zoo Biol. 15(3):341–347.

Thermoregulation

Thermal ecology of four species of *Varanus* occupying a range of habitats and climatic regions is compared to assess the efficacy of methods for evaluating the extent to which animals exploit their thermal environments. Several indices of thermoregulation are evaluated and discussed.

CHRISTIAN, K. A., AND B. W. WEAVERS. 1996. Thermoregulation of monitor lizards in Australia: an evaluation of methods in thermal biology. Ecol. Monogr. 66(2):139–157.

Snake Life History

Richard Shine uses multivariate analysis to examine life-history evolution in 103 species of Australian snakes. Two separate analyses were conducted: one treated each species as an independent unit and the other based on independent phylogenetic contrasts. Path coefficients from the two types of analyses were similar in magnitude, and highly correlated with each other, suggesting that most interspecific patterns among traits may reflect functional association rather than phylogenetic conservatism.

SHINE, R. 1996. Life-history evolution in Australian snakes: a path analysis. Oecologia 107:484–489.

Shine and Richard Seigel survey clutch-size variance among snakes, finding that the coefficient of variation did not vary significantly with maternal body size or over time within single populations. Further, clutch-size variances did not differ between viviparous and oviparous snakes, but were dependent upon allometric relationships involving maternal body size and the relationship between clutch size and body size.

SHINE, R., AND R. A. SEIGEL. 1996. A neglected life-history trait: clutch-size variance in snakes. J. Zool. 239:209–223.

Crocodilian Biology

Two recent papers by Kate Jackson and colleagues examine differences between crocodiles and alligators. In one paper the morphology of integumentary sense organs (ISOs), found in Crocodylidae and Gavialidae but not Alligatoridae, was studied using light microscopy and scanning and transmission electron microscopy. Possible functional interpretations of ISOs are discussed. A second paper studied the ability of crocodylids and alligatorids to discriminate between hyper- and hypo-osmotic salinities. The authors discuss differences in salinity discrimination as well as the historical biogeography of the Crocodilia.

JACKSON, K., D.G. BUTLER, AND J.H. YOUSON. 1996. Morphology and ultrastructure of possible integumentary sense organs in the estuarine crocodile (*Crocodylus porosus*). J. Morph. 229:315–324.

JACKSON, K., D.G. BUTLER, AND D.R. BROOKS. 1996. Habitat and phylogeny influence salinity discrimination in crocodilians: implications for osmoregulatory physiology and historical biogeography. Biol. J. Linn. Soc. 58:371–383.

Facultative Paedomorphosis

Whiteman et al. studied a montane population of *Ambystoma tigrinum nebulosum*, and measured the adult growth rate and body condition across three growing seasons to assess the relative costs and benefits of each morph. Their results suggest that paedomorphs should have decreased fitness relative to metamorphs, primarily because metamorphs can move into the best habitats for growth. The net fitness effects of morph-specific differences in dispersal depend on whether there are trade-offs with other life history traits.

WHITEMAN, H. H., S. A. WISSINGER, AND W. S. BROWN. 1996. Growth and foraging consequences of facultative paedomorphosis in the tiger salamander, *Ambystoma tigrinum nebulosum*. Evol. Ecol. 10:433–446.

Costa Rican Tadpoles

Karen Lips and Jay Savage present a key to distinguish among the described tadpoles of Costa Rican frogs and toads, summarize the reproductive modes present in this group, and present a bibliography of the published illustrations of those tadpoles.

LIPS, K. R., AND J. M. SAVAGE. 1996. Key to the known tadpoles (Amphibia: Anura) of Costa Rica. Stud. Neotrop. Fauna & Environm. 31:17–26.

Forest Management and Amphibian Ecology

Questions about the compatibility of timber harvest practices and conservation of biological diversity are largely driven by concerns that habitat quality for many species may be degraded in intensively managed forest landscapes. DeMaynadier and Hunter reviewed the literature on relationships between common forest harvesting practices and the distribution and abundance of amphibians. The authors also discuss problems commonly encountered in the experimental design and measurement of forest amphibian populations and outline several aspects of amphibian–forest relationships in need of future research.

DEMAYNADIER, P. G., AND M. L. HUNTER, JR. 1995. The relationship between forest management and amphibian ecology: a review of the North American literature. Environ. Rev. 3:230–261.

Systematics and Snakebite Treatment

The importance of a sound and explicit taxonomic framework to toxinological and clinical research and the production and use of antivenoms is discussed in a recent paper by Wüster and McCarthy. Using two species complexes as examples, the authors explore the implications of taxonomic developments for toxinology and clinical science.

WÜSTER, W., AND C. J. MCCARTHY. 1996. Venomous snake systematics: implications for snake bite treatment and toxinology. *In* C. Bon and M. Goyffon (Eds.), Envenomings and Their Treatments, pp. 13–23. Fondation Marcel Mérieux.

Molecular Systematics

Forstner et al. use mtDNA sequence data to re-examine the hypothesis of an anguimorph origin for snakes. Their results affirm earlier studies suggesting that the suborder Serpentes arose within the lizard clade and that snakes are clearly allied with anguimorph lizards (e.g., varanids). Blind snakes (Leptotyphlopidae and Typhlopidae) represent extant ancestral lineages but do not appear to be sister groups. Molecular evidence supports a fossorial or nearly fossorial origin for limblessness in snakes.

FORSTNER, M. R. J., S. K. DAVIS, AND E. ARÉVALO. 1995. Support for the hypothesis of anguimorph ancestry for the Suborder Serpentes from phylogenetic analysis of mitochondrial DNA sequences. Mol. Phyl. Evol. 4(1):93–102.

Corallus enydris (tree boa) has an extremely wide mainland distribution from southern Costa Rica to southeastern Brazil, and is one of only two boines to occur in the Lesser Antilles. Henderson and Hedges apply mtDNA sequence data to examine relationships among geographic units. These data confirm the monophyly of *C. enydris*, and reveal that the Lesser Antillean populations cluster with the southern mainland samples (e.g., Guyana, Peru, southeastern Brazil) rather than the geographically closer northern samples (e.g., Trinidad). The results suggest a recent Guianan-Amazonian origin of West Indian populations.

HENDERSON, R. W., AND S. B. HEDGES. 1995. Origin of West Indian populations of the geographically widespread boa *Corallus enydris* inferred from mitochondrial DNA sequences. Mol. Phyl. Evol. 4(1):88–92.

Reeder examines the North American phrynosomatid radiation from a molecular perspective. A cladistic analysis of mtDNA sequence data was largely incongruent with recent morphology-based analyses. The sand lizards (*Callisaurus, Cophosaurus, Holbrookia,* and *Uma*) together with *Petrosaurus, Phrynosoma, Urosaurus,* and *Uta* form a natural group. All species of *Sceloporus*, except *S. variabilis* and *S. chrysostictus*, formed a clade.

REEDER, T. W. 1995. Phylogenetic relationships among phrynosomatid lizards as inferred from mitochondrial ribosomal DNA sequences: substitutional bias and information content of transitions relative to transversions. Mol. Phyl. Evol. 4(2):203–222.

LETTERS TO THE EDITOR

Current Subspecific Names for Western *Thamnophis sirtalis*

SEAN J. BARRY
Section of Evolution and Ecology and The Rowe Program in Genetics
University of California, Davis, California 95616, USA
e-mail: sjbarry@ucdavis.edu

MARK R. JENNINGS
National Biological Service, California Science Center
Piedras Blancas Research Station
P.O. Box 70, San Simeon, California 93452, USA
and
Research Associate, Department of Herpetology
California Academy of Sciences
San Francisco, California 94118, USA
e-mail: mark_jennings@nbs.gov

and
HOBART M. SMITH
Department of Environmental, Population, and Organismal Biology
University of Colorado, Boulder, Colorado 80309-0334, USA
e-mail: hsmith@spot.colorado.edu

The taxonomy of the western subspecies of *Thamnophis sirtalis* has been resolved and well-accepted for 45 years (cf. Fox 1951). However, Boundy and Rossman (1995) suggest that the senior name for the San Francisco Peninsula *T. sirtalis* (currently named *T. s. tetrataenia*) is *T. s. infernalis*, and that *T. s. tetrataenia* should be suppressed. They suggest further that the subspecies known currently as *T. s. infernalis* (the California red-sided garter snake) should be united with *T. s. concinnus* (the red-spotted garter snake), a disjunct subspecies, but they present no systematic evidence to justify such a union.

In our view, adoption of the arrangement proposed by Boundy and Rossman will result in major and unwarranted disruption of western garter snake taxonomy. Further, the impact of this new arrangement on the conservation efforts on behalf of *T. s. tetrataenia* (the endangered San Francisco garter snake) is potentially disastrous. Well over half of the 125+ citations of "*T. s. tetrataenia*" since 1951 have appeared in the conservation literature, and this snake appears under only that name in all of the

numerous government documents concerned with endangered wildlife. To change the subspecific designation to "*T. s. infernalis*" after so many years of stability is to invite serious confusion in the lay, conservation, and governmental communities, particularly because that name is in current usage for another form.

Accordingly, Barry and Jennings (*in press*) have petitioned the International Commission on Zoological Nomenclature to conserve the accepted usage and suppress the changes proposed by Boundy and Rossman (1995). The notice of the receipt of this petition appeared on 28 June 1996 as Case 3012 in the *Bulletin of Zoological Nomenclature*, Volume 53 Part 2, page 77. Under Article 80 of the Code, previous accepted usage is to be maintained until the Commission ruling has been published. We offer this special notice of the petition because the nomenclature proposed by Boundy and Rossman has already been used in at least one further publication (Rossman et al. 1996). In light of the great potential for confusion if the Boundy and Rossman names continue to be used, we remind workers who cite the names for the San Francisco garter snake, the California red-sided garter snake, and the red-spotted garter snake that they should maintain the established, pre-1995 nomenclature, as required by Article 80 of the International Code of Zoological Nomenclature, until the ruling of the Commission is published.

and

WILLIAM G. DEGENHARDT
Department of Biology
The Unviersity of New Mexico, Albuquerque, New Mexico 87131, USA

We have discovered a number of unfortunate errors in our book since its publication. Although most are of an editorial nature and insufficient to detract substantially from the overall quality of the book, there are enough to warrant the issuing of a corrigenda. The University of New Mexico Press has elected not to do so; therefore, we have taken it upon ourselves. Following are the errors we believe are noteworthy:

p. 12 The correct citation for the Roundtail Horned Lizard is *Phrynosoma modestum* Girard *in* Baird and Girard, 1852.

p. 65 The reference to Smith et al. (1995a) in line 9, column 1 should be Smith et al. (1995b).

p. 83 The photographic reference should be to plate 23.

p. 114 The reference by Christiansen and Iverson (1993) in lines 7–8, column 2 should read "Christiansen and Iverson (in press)."

p. 116 The reference by Christiansen and Iverson (1993) in lines 7–8 and 11–12, column 2 should read "Christiansen and Iverson (in press)."

p. 127 Figure 18a is incorrect; it should be as follows:

Figure 18a

p. 154 The correct citation for the Roundtail Horned Lizard is *Phrynosoma modestum* Girard *in* Baird and Girard, 1852.

p. 203 The acronyms "GAB" and "GBPS" in Table 2 are not defined. GAB = granular scales around the body, measured at midbody; GBPS = granular scales between the paravertebral stripes.

p. 204 The lefthand column heading should read "vertebral," not "veterbral."

Fig. 2 The scale should read "900–2200," not "2000–12500," and the contour intervals are 100 m, not 500 m.

Fig. 3 The order of the color rectangles should be blue-green-yellow-brown, not blue-yellow-brown-green.

Pl. 82 The animal pictured is from Socorro County, not Otero County.

Pl. 84 The animal pictured is from Eddy County, not Otero County.

Pl. 99 & 100 The legends for these two photographs have been transposed; plate 99 is a *Salvadora deserticola* and plate 100 is a *Salvadora grahamiae*.

p. 238 Substitute "*Liochlorophis*" for "*Opheodrys*" in line 10, column 2.

p. 315 Insert "a" following "1853" in line 18, column 1.

p. 370 Read "oviductal" instead of "oviducal."

p. 370 Under the definition of the word 'paralectotype,' read "syntypic" or "type" instead of "syntopic."

p. 380 The reference by Christiansen and Iverson is in press.

p. 382 The following reference, cited in the *Masticophis flagellum* account, is missing: Cope, E.D. 1875. Checklist of North American Batrachia and Reptilia; with a systematic list of the higher groups, and an essay on geographical distribution. Based on the specimens contained in the U.S. National Museum. Bull. U.S. Natl. Mus. (1):1–104 p.

p. 387 The paper by Ford and Cobb (1992) is cited incorrectly; the correct reference is: "Timing of courtship in two colubrid snakes of the southern United States. Copeia 1992(2):573–577."

p. 393 Under the reference by Iverson (1981), remove the word "group" contained within the parentheses, and insert the abbreviation "Bot." following "Zool." in the name of the periodical.

p. 409 The citation by H.M. Smith (1937) should have the word "synopsis" substituted for the words "new subspecies."

The EMBL/EBI Reptile Database

Several million species of living organisms inhabit the Earth. Among them are about 8000 reptiles. Several attempts have been made to put some order into this vast diversity, most notably by the series "Das Tierreich" which was published originally by the German Zoological Society. Besides listing all animal species, the "Tierreich" also aimed to list all synonyms for a given taxon, an indispensable feature in order to avoid complete confusion among the several scientific names most species have received since their first description. For example, the recent list of Australian and Oceanian geckos by Bauer (1994) revealed more than 800 different names for about 170 geckos of this region!

Species:
Vipera monticola
Synonyms:
1953 Vipera latastei montana Saint Girons
1954 Vipera latastei monticola Saint Girons

FIG. 1. Sample entry from species database.

A comprehensive taxonomy of reptiles and amphibians is the basis for both systematic and all other aspects of herpetology, hence it should be widely available and constantly up-to-date. In contrast to books and journals these two criteria are only met by electronic databases on the Internet. To our knowledge there is no online database on reptile species available so far. The only comprehensive Internet database on vertebrate species to date is an online version of the venerable *Mammal Species of the World* (Wilson and Reeder 1993). For this reason we set up a prototype database which is based on the Sequence Retrieval System (SRS), originally developed for the access of DNA and protein sequence data over the internet (Etzold et al. 1996).

The aim of the database is the collection and dissemination of taxonomic data on all living reptiles. For this purpose the database is split into two parts, a species database and a database on higher taxa. Currently the **species database** contains about 7600 species, of which about 6300 have some information on distribution associated. More than 3000 species entries contain references to more detailed sources (which in most cases also include pictures). An entry consists of six data fields, although additional fields may be added later (Fig. 1).

The species entries currently contain little information apart from some data on the distribution of particular species. Hence, we welcome submission of such data (including detailed descriptions) from the herpetological community. For the time being, only data that have been published regularly will be entered until a scientific advisory board has been established that might review direct submissions. Technically, it is no problem to include pictures and distribution maps as well, although the short-term goal of the database is a text-based catalog of all reptile taxa.

Entries of the **higher taxa** database (Fig. 2) are similar to the species entries:

ID:
Taxon:
Tropidurinae
Synonyms:
1843 Tropidurinae Bell
1843 Ptychosauri Fitzinger
1843 Steirolepides Fitzinger
1843 Heterotropides Fitzinger
Category:
Subfamily
Up:
Tropiduridae
Status:
valid
Description:
premaxillary spine not overlapped by nasals
parietal table not Y- or V-shaped
no labial blade or coronoid
splenial extending anteriorly no more than 1/6 length of precoronoid length of mandible
anterior process of interclavicle poorly developed or absent
interparietal scale enlarged
no preanal pores
nasal concha fused to roof of nasal chamber
nasal vestibule relatively short and straight
bisulcate, weakly to strongly bicapitate hemipenes
Comment:
Bell's Tropiduridae seems to have priority over Fitzinger's Steirolepides, Ptychosauri, and Heterotropides

FIG. 2. Higher taxon sample entry.

The higher taxon database is currently under development and not yet available to the public. We expect release in January 1997. It will allow automatic reconstruction of taxonomic hierarchies by means of the "Up" data field, e.g., all lower taxa of a family or all higher taxa pertaining to a species.

The database can be accessed easily on the World Wide Web. A form allows for quick searching of different data fields (e.g., species or distribution). Logical combinations are possible (e.g., "*Tantilla*" OR "*Coluber*" combined with "USA" OR "Mexico" searches for all *Tantilla* and *Coluber* species in both Mexico and the USA).

Alternatively, the database can be browsed via hierarchically organized web pages starting with a taxonomic overview (subclasses, orders, suborders). From there, infraorders/superfamilies, families, and genera can be accessed. Clicking on a single genus

eventually activates the search engine and retrieves all species of a particular genus.

A major advantage of the SRS system is its ability to be linked to other databases. So far, we have implemented a link to the GenBank DNA sequence database. Thereby, it is possible to search for all species of, say, *Anolis* and list all available sequence data alongside. In the future it is expected that other areas of biology will be made available as databases as well. It can easily be conceived that databases of taxonomy and molecular biology, and eventually of morphology, ethology, and other disciplines will be flexibly intertwined as they deserve to be from a biological viewpoint.

In the long run, newly described species should be entered into the database in addition to regular publication. We encourage herpetological journals to adopt a policy similar to molecular biology journals, requiring parallel submission of manuscripts to the journal and primary data to the database. (Note that many molecular biology journals do not print DNA sequence data anymore but refer readers to an accession number in a public DNA database.) For instance, *Herpetological Review* might ask authors for submission of new distribution data to the database before publication. The database would then also serve as a public repository for all these data.

The database should be considered as an experiment for the time being. We are well aware of the fact that the data are incomplete, and some may be outdated or even wrong. The success and usability therefore depend on the contributions of external experts. In particular, we are seeking specialists interested in serving as coordinators (or "reviewers") for higher taxa. Additional information for contributors may be found on our web page.

We are in great debt to people who provided species lists or other information, in particular Petr Neças (Chamaeleonidae), Klaus Adolphs (Gerrhosauridae, Cordylidae), Hermann Seufer (Gekkonidae), Wolfgang Bischoff (Lacertidae), and Adam Britton (Crocodylia). Drs. Stephen Brown, Wolfgang Wüster, and Scott Moody made helpful comments on this note.

INSTITUTIONAL PROFILE

The Early Collections and Curators, Division of Reptiles and Amphibians, Museum of Zoology, University of Michigan

ARNOLD G. KLUGE
Museum of Zoology, University of Michigan
Ann Arbor, Michigan 48109-1079, USA

A large number of amphibians and reptiles had accumulated in the Museum of Zoology by the time the Division of Reptiles and Amphibians was officially recognized in 1917 (H. T. Gaige 1920; Rogers 1956; Ruthven 1920). Actually, the history of the Museum's collections can be traced to June 21, 1837[1] when the Michigan State Legislature budgeted for a Cabinet of Natural History, renamed the Museum of Natural History in 1881 (Ruthven 1910). Among the earliest specimens acquired by the University was a *Bufo americanus* (UMMZ 20), contributed by Professor Abram Sager in 1837, from the southeast part of the state. As early as 1863, there were 81 amphibian entries representing 212 specimens, and 290 reptile entries representing 336 specimens (Winchell 1864:17). Many of these early specimens were part of the Trowbridge Collection, which was donated by the Smithsonian Institution in 1859. Much of that collection was obtained by Lieutenant William Petit Trowbridge, a University of Michigan professor, while in the United States Army during his tour of duty along the Pacific Coast, from San Diego to Puget Sound (1853–1856). Other significant early sources of materials were the Beal-Steere collections, which were made by Professor Joseph Beal Steere in South America and the Orient during his trip around the world in 1870–1875 (Winchell 1871, 1873) and subsequent expeditions in 1879 and 1887–1888 (F. M. Gaige 1932; Rogers 1956). Although most of the early catalogued amphibian and reptile material is no longer available, there are some interesting exceptions. For example, there remain two well preserved *Ambystoma tigrinum* (UMMZ 150) collected by W. J. Beal in 1857 from Lenawee County, Michigan, and two *Nerodia sipedon* (UMMZ 38) in equally good condition, collected by R. Frazer on May 2, 1858, from Ann Arbor. Unfortunately, very few of the Division's Trowbridge and Beal-Steere specimens can be located. In addition to the actual catalogues in which amphibians and reptiles are registered, details of the early accessions were published in University of Michigan, Museum of Zoology (1861) and Winchell (1864, 1866, 1867, 1868, 1870, 1871, 1873).

[1] The Museum of Comparative Zoology at Harvard University and the Peabody Museum of Natural History at Yale University were founded in 1852 and 1866, respectively (Guthe 1937).

Many science faculty had responsibility for the Museum collections in the early years, including Asa Gray (1838), Abram Sager (1842–1855), Alexander Winchell (1855–1873), Mark W. Harrington (1873–1876), Joseph B. Steere (1876–1894), Jacob E. Reighard (1894–1895), Dean C. Worcester (1895–1898), Herbert E. Sargeant (1898–1903), and Charles C. Adams (1903–1906). Alexander G. Ruthven (1906–1936) was the first professionally trained herpetologist to curate the amphibians and reptiles. He was ably assisted early in his curatorship by Helen Thompson (1912–1918) and Crystal Thompson (1914–1918), who were friends, but not related by birth (Fig. 1). Helen Gaige (née Thompson) was given an official curatorial title in 1919, a position she held until her retirement in 1945. More recent Divisional Curators (Figs. 2–4) were Norman E. Hartweg (1934–1964), Charles F. Walker (1947–1975), and Donald W. Tinkle (1965–1980). Other notable students of amphibian and reptile biology on the University of Michigan faculty, but who did not hold curatorships in the Division, include Reeve M. Bailey, Frank N. Blanchard, William R. Dawson, Carl Gans, Howard K. Gloyd, Nelson G. Hairston, George W. Nace, Laurence C. Stuart, and Frederick H. Test.

FIG. 1. A University of Michigan Museum of Zoology field trip to Schoolcraft County, Michigan, July–August, 1915. Crystal Thompson, Frederick M. and Helen T. Gaige, and Alexander G. and Florence H. Ruthven, from left to right. Crystal Thompson, Helen T. Gaige, and Alexander G. Ruthven curated the amphibian and reptile collections in the Museum of Zoology in the early part of this century, 1914–1918, 1912–1945, and 1906–1936, respectively.

Alexander Grant Ruthven is an extremely important figure in the history of the Division of Reptiles and Amphibians, as he is for the Museum of Zoology and the University of Michigan (Van de Water 1977). The large numbers of specimens acquired by the Division in the early part of this century were due to his field work and particular interest in the study of geographic variation with statistical methods, which led him to emphasize the acquisition of large local samples. He personally led 18 expeditions from the Museum of Zoology (F. M. Gaige 1930), which included major field excursions to the Porcupine Mountains, Ontonagon

County (1904), and Isle Royale (1904 and 1905), Michigan, Clay County and Palo Alto County, Iowa (1907 and 1909), Vera Cruz, México (1910), northeastern Nevada (1912), the Davis Mountains, Texas (1913 and 1915), the Santa Marta Mountains, Colombia (1913), Richland County, Illinois (1913), the Demerara River, British Guiana (1914), and the Pisgah Forest Reserve, North Carolina (1915). "To him museum collections and data were one of the essential tools for deciphering the course and much of the mechanism of evolution, and a *sine qua non* for the construction of a systematics that could aspire to an accurate presentation of taxonomical relationships" (Rogers 1956: 1503). In 1913, the Board of Regents of the University renamed the Museum of Natural History as the Museum of Zoology and appointed Ruthven as its first Director. Division of Reptiles and Amphibians, the official name for the collection of amphibians and reptiles in the Museum, stems from Ruthven (1917:6), although it has not been applied consistently (e.g., Ruthven 1920; H. T. Gaige 1920). It was with Ruthven's considerable effort, beginning in 1918, that funds were secured for the present Museums Building (Fig. 5), which opened in 1928 (Ruthven 1929). Although Ruthven resigned the directorship of the Museum of Zoology and accepted the presidency of the University in 1929, he did not give up his curatorship until 1936. Ruthven was a prolific researcher, with 160 authored or co-authored professional papers bearing his name. He was among the first to publish in the Museum's *Occasional Papers* (1913) and *Miscellaneous Publications* (1922), journal series which he initiated. Ruthven et al.'s (1912, 1928) "The Herpetology of Michigan" continues to serve as a model for state field guides, and his published doctoral thesis, "Variations and Genetic Relationships of the Garter-Snakes," remains a classic study of geographic variation (Ruthven 1908).

FIG. 2. Norman E. Hartweg, Curator (1934–1964), Division of Reptiles and Amphibians, University of Michigan Museum of Zoology.

FIG. 3. Charles F. Walker, Curator (1947–1975), Division of Reptiles and Amphibians, University of Michigan Museum of Zoology.

FIG. 4. Donald W. Tinkle, Curator (1965–1980), Division of Reptiles and Amphibians, University of Michigan Museum of Zoology.

All natural history acquisitions were registered in the same number series early in the Museum's history, and those nine bound volumes are now stored in the Museums Library security cage. In 1916, four separate vertebrate catalogues were initiated, each beginning with number 52001. Volume 11 started the amphibian and reptile series, which lasted until 1975 when volume 21 was completed, and when the Division switched to TAXIR, a mainframe computer database management system. The Division now uses FoxPro in a distributed computing environment to manage electronically all aspects of its collection records. During the last five years, collection growth has averaged more than 4400 specimens per annum. According to the most recent annual report (1994–1995), the Division's holdings have grown to more than 209,000 numbered lots, which represent nearly 400,000 specimens.

That significant herpetological research has been done at the University of Michigan from a very early date is indicated by the fact that of the two Doctor of Philosophy degrees first awarded by the University, in 1876, one was to William Henry Smith for his thesis entitled "The zoology of Anoura and Caecilia." Smith went on to publish his doctoral research (1877), as well as other works dealing with the herpetofauna of Michigan and Ohio (1879, 1882). According to Ruthven et al. (1928:185), Smith's Michigan catalogue (1879) was based in part on the specimens in the University of Michigan Museum. From the time of Alexander

FIG. 5. West end of the reptile range, Division of Reptiles and Amphibians, University of Michigan Museum of Zoology, at the completion of the new Museums building, 1928.

Ruthven well over 50 Ph.D. students have received their degrees under the guidance of curators in the Division of Reptiles and Amphibians.

Further details concerning the Division of Reptiles and Amphibians are available by the World Wide Web: http://www.ummz.lsa.umich.edu/herps/herpdiv.html. These include bibliographies for past curators, H. T. Gaige, N. E. Hartweg, A. G. Ruthven, C. Thompson, D. W. Tinkle, and C. F. Walker, a list of students earning Ph.D. degrees whose major professor was a Curator in the Division, annual reports, and various policy statements pertaining to the use of specimens and other materials in the Division's care.

Acknowledgments.—Kraig Adler, Richard Etheridge, and Ron Nussbaum offered critical comments on the manuscript. A great deal of gratitude is owed to the late Ted Hubbell, Curator of Insects and Director of the Museum of Zoology, for convincing me that an institution's history is both interesting and important.

Biology, Status, and Management of the

Timber Rattlesnake

(*Crotalus horridus*): A Guide for Conservation

William S. Brown

This timely work is once again available in a second printing, and continues to set the standard nationwide for conservation programs involving North America's pitvipers. Featuring sixteen stunning color photographs of Timber Rattlesnakes that demonstrate the extraordinary diversity of colors and patterns displayed by this variable species throughout its range, Brown's savvy approach to promoting the protection of this reptile is shown in the contents of this work, as follows: Introduction, Description, Distribution, Habitat, Ecology, Determination of Occurrence, Threats, Land Protection, Recovery Potential, Biological Monitoring Procedures, Biological Monitoring Programs, Research Needs, Research Programs, Management Procedures, Management Programs, Summary of Conservation Biology, Acknowledgments, and an extensive Bibliography. A must for anyone interested in venomous snakes and their conservation. Includes two exceptional line drawings by Donald G. Wheeler (cover) and John Lokke (frontispiece). vi + 78 pages. ISBN 0–916984–29–X. 1993. US $9.00 per copy.

"... a passionate and reasoned monograph that underscores the need for regulations to stop the 'shocking decline' and near extirpation ... of the Timber Rattlesnake."
Jane O'Connell, *Adirondac*

"The book is unique in being the first devoted to the conservation of a snake."
Henry S. Fitch, *University of Kansas*

"... a detailed compendium of what is currently known of the natural history of the [Timber Rattlesnake]"
Roger Avery, *Amphibia-Reptilia*

Orders may be sent to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA
(Include US $9.00 per book plus $1.00 for first copy and $0.50 for each additional copy to cover handling and postage)

ARTICLES

Daily Movements of Male *Phyllomedusa bicolor* in Brazil

SELVINO NECKEL DE OLIVEIRA
Departamento de Ecologia
Instituto Nacional de Pesquisas da Amazonia - INPA
C. P. 478, 69011-970 Manaus, Amazonas, Brasil

Calling sites of many anuran species are usually in close proximity to ponds or streams (Zimmerman and Rodrigues 1990). Little is known, however, concerning the location of daily retreat sites of arboreal species. These sites must certainly be sufficiently moist to prevent desiccation (Duellman and Trueb 1986) and offer some protection against predation. Neotropical frogs of the genus *Phyllomedusa* are arboreal and nocturnal. During breeding periods, males can be observed on perches near ponds and streams (Zimmerman and Rodrigues 1990). *Phyllomedusa bicolor*, the largest species in this genus, exhibits the common behavior of calling from perches, although it can be seen occasionally on the forest floor (pers. obs.). As with most anurans, no information exists as to the daily retreat sites of this species.

The objectives of this study were 1) to identify diurnal retreat sites of calling males of *P. bicolor*; 2) to measure the distance of the retreat site to the calling site; and 3) to compare distance traveled on the forest floor to distance in shrubs and trees.

Observations and marking of individuals were performed 23–30 May 1994 in the Adolfo Ducke Reserve, ca. 25 km north of Manaus, Amazonas, Brazil (3°8'S, 60°4'W). The reserve measures 100 km^2, and is covered in humid tropical rainforest not subjected to annual flooding (Kahn and Castro 1985). Work was carried out at four distinct sites within the reserve: one small pond (5 m wide by 11 m long) located close to a stream, and three ponds (0.3–3 m wide by 24–33 m long) formed by wheel ruts along an access road. Ponds were visited at night and nine males and one female were encountered at these sites and used in this study. All animals were measured (SVL) and weighed. To identify retreat sites of calling males and measure distance traveled from the calling perch to the retreat site, a small spool of fine nylon thread was attached to each calling male. Spools were encased in plastic and attached dorsally to males in a backpack fashion. The loose end of the thread was then tied to the perch and the animal was replaced on the perch where it had been calling. The female was replaced on the same branch where it had been taken. The entire apparatus weighed less than 3.5 g (ca. 4–7% of male body weight).

Retreat sites were identified by visiting the sites on mornings following nocturnal markings. The thread was followed for each marked animal and retreat sites identified. The distance between the retreat site and the calling perch (or observation locale for the female) was estimated by measuring the thread along its entire path. The proportion of the total distance that was traveled on the ground and above ground was calculated by following the thread.

Mean weight for males was 68 g (± 9 g), and mean SVL was 105.9 mm (± 4.4 mm). The lone female weighed 98 g and measured 115 mm. Overall daily movement distance varied considerably among males from 6.5–46.6 m (mean 26.1 ± 10.7 m) (Table 1). Distance traveled on the forest floor was highly variable (mean 8.3 ± 7.0 m) as was that on vegetation (mean 17.8 ± 8.1 m). Only two males did not travel on the forest floor. The lone female traveled 17.3 m on the forest floor and 21.3 m on vegetation.

Exact retreat site location was identified for only five males and the female. For the other marked animals, the thread could be seen in the tree, but I was unable to follow it entirely to the animal. The retreat site for these individuals was estimated by measuring the thread until it disappeared in the canopy. Therefore, the mean height of the retreat sites is an underestimation. Retreat site height for males varied from 1.5–9.0 m (mean 6.3 ± 2.6 m). The height of the female's retreat site was 5.3 m. All retreat sites were on small branches less than 1 cm in diameter.

Because of the loss of spools, only two males were observed on consecutive nights. Both animals used the same retreat site on both nights and the same route to get there.

TABLE 1. Daily movements (in m) of male *Phyllomedusa bicolor* from calling sites to retreat sites. Data for a single female also are included. Individuals 1 and 2 were observed on two consecutive nights and the values are reported here. An asterisk denotes males for which the exact retreat site could not be located. Values for these individuals were estimated on the position of the thread in the canopy.

	Distance Travelled					
	Forest Floor		Vegetation		Total	Retreat site
	m	%	m	%	m	m

Male *P. bicolor* were encountered resting on small branches high up in the vegetation during the day as suggested by Duellman and Trueb (1986). During daily resting, anurans must escape predation and prevent desiccation. Because *P. bicolor* individuals possess lipid glands in the epithelium whose secretions protect the animal from desiccation (Blaylock et al. 1976), this species probably can withstand unfavorable conditions better than others. My observations that two males used the exact same retreat sites suggests that these sites are not chosen randomly and that "good" sites are reused by the same individual. Schlesinger and Shine (1994) showed that the nocturnal lizard *Oedura lesueurii* was highly selective in its choice of diurnal retreat sites, behavior that decreases exposure to predation and allows thermoregulation.

The long distance traveled on the forest floor by individuals of *P. bicolor* remains to be explained. This species has very large toe pads and therefore would be expected to spend most of its time off the ground. The slow-moving behavior of this species and its relatively poor jumping ability (pers. obs.) may make a route to retreat sites that includes forest floor travel plausible.

Daily movement of anurans has been related to feeding, predator avoidance, reproduction, and physiological maintenance (Bayliss 1994; Breden 1987; Dole 1965; Woolbright 1985). Some species have been observed to migrate long distances in search of food, as shown for *Rana pipiens* (40–160 m; Dole 1965), *Bufo bufo* (45–75 m; Gittins 1980), and *B. marinus* (mean = 141 m per night; Bayliss 1994). Daily movements related to reproductive behavior are generally much shorter, as seen for *R. pipiens* (0–32 m; Dole 1965) and *Eleutherodactylus coqui* (3.0–4.5 m; Woolbright 1985). In this study, daily movements of *P. bicolor* suggest that individuals remain in close proximity to vocalization sites. However, few of the above-mentioned species are truly arboreal, and therefore comparisons of daily movements should be made with caution.

Acknowledgments.—This study was performed during the field course "Ecology of a Tropical Rainforest" offered by the Ecology Department of the National Institute for Amazonian Research. I wish to thank W. Magnusson, R. Vogt, and C. Gascon for their supervision and suggestions. A. S. B. De Faveri, A. Carvalhaes, and students from the Graduate Program in Ecology at INPA are thanked for helpful discussions and suggestions (G. Mourão, C. C. Durigan, J. Maco Garcia, M. A. Freitas, M. Gordo, and U. Galatti).

Interclutch Interval and Egg Aggregations in the Tropical House Gecko, *Hemidactylus mabouia*

BRIAN C. BOCK
Fundación Natura, AA 55402
Bogotá, Colombia

Present address: U.S. Man and the Biosphere Program
OES/ETC/MAB, Suite 107, SA-44c

e-mail: bbock@state.gov

Hemidactylus mabouia produces clutches of two eggs, which are deposited in crevices and under debris (Dixon and Soini 1986; Rivero 1978; Vitt 1986). Aggregations of up to 60 *H. mabouia* eggs have been interpreted as evidence for communal nesting in this species (FitzSimons 1943). In northeastern Brazil, Vitt (1986) encountered gravid *H. mabouia* throughout the year, some of which contained both vitellogenic follicles and oviductal eggs, implying that females may be capable of producing numerous clutches per year. Here I present additional data which suggest that annual fecundity in *H. mabouia* may be high, as well as evidence that some aggregations of eggs in this species are the result of repeated use of the same oviposition site by individual females, rather than communal nesting.

Hemidactylus mabouia occurs in association with human settlements throughout much of the Amazon basin (Dixon and Soini 1986; Kluge, 1969; Sánchez et al. 1995; Vitt 1986). This study was conducted in the town of La Pedrera, Amazonas Department, Colombia, located on the Caquetá river near the border with Brazil (1°18'S, 69°33'W). Unlike Vitt's (1986) Brazilian study site, this area lacks a well defined dry season, with average monthly rainfalls of at least 135 mm throughout the year (Duivenvoorden and Lips 1993). *Hemidactylus mabouia* is a good colonizer (Kluge 1969; Lawson et al. 1991; Meshaka et al. 1994) and probably dispersed to La Pedrera via cargo flights from Leticia. It apparently has not yet spread to any other nearby human settlements along the Caquetá river.

I encountered four aggregations of *H. mabouia* eggs while renovating an abandoned house in La Pedrera (Table 1). In one case, I encountered only intact eggs, but the other groups contained both incubating eggs and shell fragments from eggs that presumably had already hatched. It was possible to estimate the number of eggs that had already hatched in one of these aggregations. All aggregations were found during the months of September and October, but this should not be considered as evidence for seasonal nesting at this site. Rather, these months were periods of more intensive work on the house renovations. Juvenile *H. mabouia* were seen in the house throughout the year.

Eggs sizes (mean egg length = 9.8 mm, SD = 0.49; mean egg width = 8.7 mm, SD = 0.43; N = 14) were comparable to those reported for this species from other neotropical sites (Dixon and Soini 1986; Schwartz and Henderson 1991; Vitt 1986), but smaller than those reported from South Africa (FitzSimons 1943). I rolled intact eggs from each aggregation into pieces of tissue paper and enclosed them in inflated plastic bags. The eggs experienced ambient indoor temperatures which fluctuated between 25°C and 32°C. The bags were checked daily and any newly emerged

hatchlings were removed, measured, and released. Hatchling sizes (mean SVL = 23.4 mm, SD = 1.07; mean tail length = 25.3 mm, SD = 1.78; N = 18) were comparable to those reported for this species from other neotropical sites (Dixon and Soini 1986; Hoogmoed 1973; Schwartz and Henderson 1991; Vitt 1986), but smaller than those reported from South Africa (FitzSimons 1943).

TABLE 1. Summary of information on the four aggregations of *Hemidactylus mabouia* eggs encountered in this study. In two cases, shell fragments were too small to permit an accurate estimation of the number of eggs that had already hatched.

Group	Location	Number of eggs: estimated already hatched	found still incubating	to eventually hatch
1	in a cavity created within a wooden beam by termite activity	25	3	2
2	in a crevice under a flat rock	0	6	6
3	among coals and ashes in an abandoned stove	?	7	7
4	among coals and ashes in an abandoned stove	?	4	3

Two eggs from the smallest aggregation hatched on the same day and the third egg failed to hatch. In the other three groups, eggs also tended to hatch nearly simultaneously in pairs. The interval between hatching of pairs of eggs within these groups was approximately 16 days, or some multiple thereof (Fig. 1). The emergence of hatchlings in pairs suggests that female *H. mabouia* usually lay both eggs of a given clutch together. The regular periodicity of hatching of pairs of eggs within groups also suggests that females in this population produce clutches on average every 16 days and that they tend to return to the same oviposition site for successive clutches. In only one instance did a pair of eggs hatch out of synchrony with the other eggs with which they were associated (group 3b, Fig. 1). This probably resulted from true communal nesting (i.e., from a second female laying in a site where another female had already deposited several clutches).

Although the total incubation period for *H. mabouia* eggs in this population is not known, the maximum period between encountering an egg and its hatching in this study was 71 days. Dixon and Soini (1986) reported an encounter-to-hatching time for a *H. mabouia* egg in Perú of at least 77 days. Thus, with an interclutch interval of 16 days, any aggregation of up to ten incubating eggs could conceivably have all been laid by a single female. Larger aggregations of eggs in this species probably represent the occurrence of both communal nesting and repeated use of the same nesting site by individual females, as has been demonstrated also in *Ptyodactylus hasselquistii* (Werner 1986).

Hemidactylus mabouia appears to reproduce throughout the year, both at La Pedrera and at more seasonal sites (Butterfield et al. 1993; Vitt 1986). Thus, a female with a 16-day interclutch interval could conceivably lay up to 46 eggs annually. The aggregation of 28 eggs and egg shells documented by this study may well have been the result of repeated use of the same oviposition site by a single female rather than of communal nesting. Although

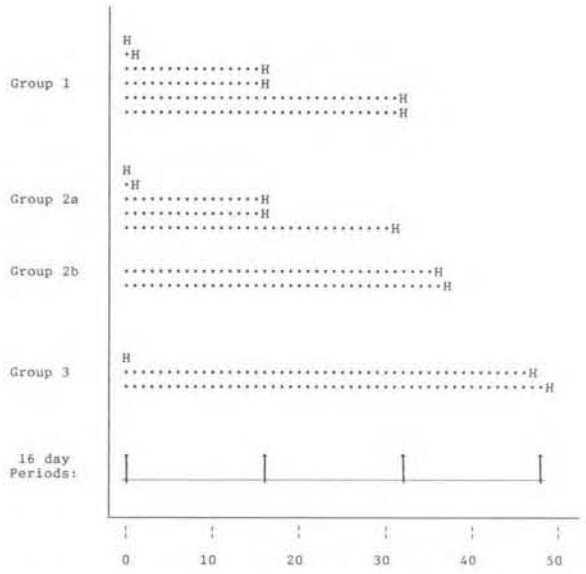

FIG. 1. Pattern of hatching (H) in the aggregations of *Hemidactylus mabouia* eggs, beginning with the day the first egg in each group hatched. Intervals of 16 days are indicated by the arrows. Eggs in group 3a were probably laid by one female and those in group 3b by another female at the same site.

H. mabouia may occasionally nest communally, not all aggregations of viable eggs and hatched egg shells should be interpreted as such. The pattern of inter-hatching intervals exhibited by the aggregations of eggs in this study suggests that when there is an abundance of oviposition sites, female *H. mabouia* may prefer to lay repeatedly in sites not in use by other females.

Three adult specimens of *H. mabouia* were deposited as vouchers (ICN 7252-54) in the collections of the Museo de Historia Natural, Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Bogotá.

Acknowledgments.—Field work in Colombia was financed by the Fondo Colombiano de Investigaciones Científicas y Proyectos Especiales "Francisco José de Caldas" – Colciencias and by the Wildlife Conservation Society. Special thanks to the Tortoise and Freshwater Turtle Recovery Program of the American Museum of Natural History and the Tortoise and Freshwater Turtle Specialist Group of the IUCN – World Conservation Union, as well as the Chicago Zoological Society, for funds for the purchase of the house as a field station. Olga Castaño helped with species identification. The manuscript benefited from the comments of an anonymous reviewer and Y. L. Werner.

Surveys for calling amphibians have become increasingly popular in recent years. Most North American programs are located in northern and eastern portions of the continent, where anurans call during their breeding season. In 1991, the Iowa Department of Natural Resources' (DNR) Wildlife Diversity Program initiated an annual Frog and Toad Survey to update species distribution maps and provide data for a long-term study on amphibian population trends. As of 1994, 69 of Iowa's 99 counties had at least one survey route. Survey participants are provided with an audio tape of the calls of Iowa anurans, and a copy of *The Salamanders and Frogs of Iowa* (Christiansen and Bailey 1991). Volunteers develop a route, consisting of five or more likely breeding sites within a single county. Observers are instructed to visit each site once during each of three time periods: 1–28 April, 7 May–4 June, and 13 June–10 July. Upon reaching a site, participants are to listen for five minutes after anurans begin calling and record all species heard. The present study is an examination of the benefits and difficulties associated with data from the Iowa Frog and Toad Survey based on our follow-up studies of reports of *Pseudacris crucifer* in central Iowa. It also reports a large range extension for the species in Iowa.

Since 1991, *P. crucifer* has been reported by survey participants from five central Iowa counties where the species was previously unknown. These include: the Des Moines River drainage counties of Boone and Hamilton; Marshall County in the Iowa River drainage; Sac County in the Raccoon River Drainage; and Ringgold County on the Iowa-Missouri border (Fig. 1). These locations range from 100–200 miles west of the previously known Iowa range of *P. crucifer* (Fig. 1). In April and May 1995, the authors visited these localities during peak calling time to verify the presence of *P. crucifer*. Aural surveys were conducted at each location on nights when the species was heard calling elsewhere. All anuran species heard calling at each location were recorded, and a single voucher specimen of each species was usually collected. The specimens were deposited in the Drake University Research Collection under DNR Permit # SC-255-9501.

The follow-up studies and collections verified the presence of *P. crucifer* at two locations in Boone County, but failed to support the existence of the species in Marshall, Ringgold, Hamilton, and Sac counties (Fig. 1, Table 1). While the possibility exists that *P. crucifer* is present at some of these sites, we believe that our multiple site visits reduce the risk of not detecting an extant population. Of the sites at which *P. crucifer* was found to be absent, only the Ringgold and Marshall County sites were visited a single time (Table 1), and the Ringgold County visit was under ideal conditions when the species was calling elsewhere. The Ringgold County site was isolated well away from a major water course and four other species were heard calling there (Table 1). It is more likely that an extant population was not detected at the Marshall County site. It is located close to the Iowa River and was visited in mid-April on a night when air temperatures were low (4–7°C).

The discovery of *P. crucifer* in Boone County suggested that they may be found farther north in the Des Moines River valley, and as such, we extended the survey north into Webster County. *Pseudacris crucifer* was subsequently found at two locations in that county along the Des Moines River (Fig. 1). The Boone and Webster County locations are new county records and constitute a significant northwestward extension of the previously known range in Iowa (Christiansen and Bailey 1991). Additionally, Fig. 1 shows a new locality established for this species in Appanoose County, where neither Iowa Frog and Toad Survey participants nor previous surveys had found them.

This study demonstrates one of the most valuable aspects of the DNR survey, that of calling attention to previously unknown localities. While *P. crucifer* was not found at all of the locations, by following leads provided by the DNR survey, we were able to extend the known range of the species approximately 100 miles northwest in the Des Moines River drainage, and slightly over 100 miles west of all previously known Iowa *P. crucifer* populations. The study also illustrates some apparent problems with volunteer-based surveys. Other authors have also addressed the advantages and disadvantages of calling surveys (Bishop et al. 1996; Scott and Woodward 1994).

The potential for species misidentification arises when relatively untrained individuals provide locality records without expert, specimen, or photographic verification. It is clear from at least one instance that an observer confused the call of *P. crucifer* with that of *Acris crepitans*. The authors visited the Sac County sites with the volunteer observer and asked the observer to identify the *P. crucifer* call. The call identified by the observer turned out to be that of *A. crepitans*. A specimen was subsequently collected and shown to the observer. It is also likely that some observers may have confused the call of *P. crucifer* with that of *Pseudacris triseriata*, because *P. crucifer* and *P. triseriata* are heard calling in a mixed chorus on the species identification tape sent to volunteers. Many participants in the survey are elderly, and evidence suggests that for those who have lost the upper range of

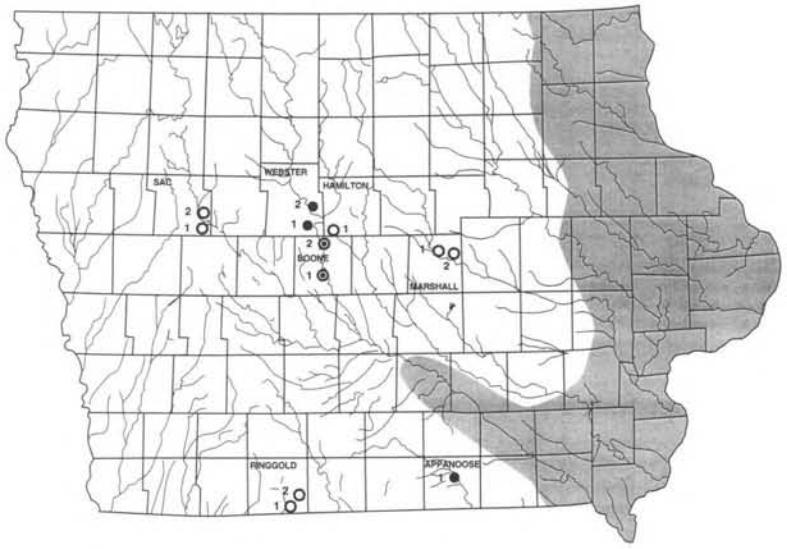

FIG. 1. Reported localities and previously known range of *Pseudacris crucifer* in Iowa. Open circles = localities reported by Iowa Frog and Toad Survey participants for which repeated visits failed to yield evidence of *P. crucifer*. Open circles with centered dots = localities reported by Iowa Frog and Toad Survey participants that yielded *P. crucifer* and prompted further studies of the Des Moines River valley. Closed circles = new *P. crucifer* localities discovered during the present study. Shaded area = known range of *P. crucifer* at the time of Christiansen and Bailey (1991).

their hearing, only *P. triseriata* can be heard on the DNR tape, and possibly in the field. The potential for inter-observer variation is illustrated by the Hamilton County site. *Pseudacris crucifer* was reported from the site by an observer in 1994, but another pair of observers have not reported the species during surveys of the same site from 1991–1994.

At a time when amphibian populations are thought to be declining worldwide, annual regional surveys, such as the Iowa DNR Frog and Toad Survey, are an inexpensive way of collecting information regarding anuran distribution and relative abundance. All calling amphibian surveys suffer from statistical problems similar to those experienced by ornithologists in programs such as the North American Breeding Bird Survey. Currently, the North American Amphibian Monitoring Program is attempting to develop a statistically defensible means of detecting changes in

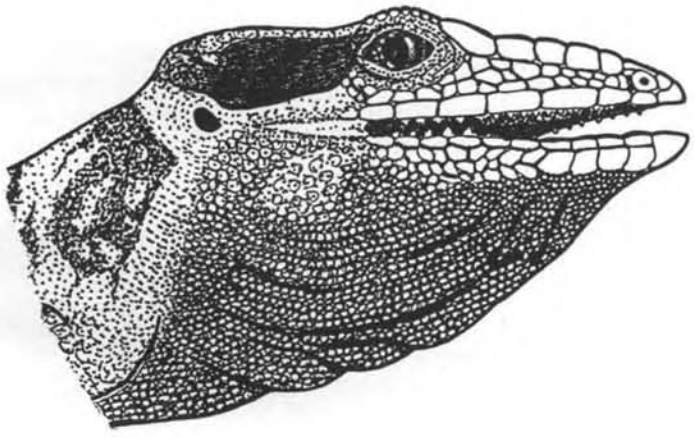
anuran distributions and populations. Volunteers trained to identify anuran calls are essential to these programs, and the present study clearly shows the value of their work. It also shows the need for verification by professionals.

Accuracy of data obtained from the Iowa DNR survey could be increased with improvement in three areas. At present, volunteers are not provided with any formal training in identifying anuran calls. Implementing an annual or biannual training program would increase observer accuracy, help with volunteer recruitment efforts, and may keep volunteers active from year to year. Improving the species identification tape may also increase observer accuracy. Most species on the tape are heard calling in mixed choruses of two or three species. Changing the tape so that species are heard individually would help observers identify specific calls. Lastly, species are often reported from outside their known range. Verification of the most reliable of these reports by professional herpetologists may lead to the discovery of previously unknown breeding sites, as demonstrated by the present study.



Acknowledgments.—We thank Dr. Terry Little and Lisa Hemesath of the Iowa Department of Natural Resources for permission to use their data and for reviewing the manuscript.

Regurgitation by the American Alligator

ROBERT H. CHABRECK

Baton Rouge, Louisiana 70803, USA

The presence of gastroliths in stomachs of American alligators (*Alligator mississippiensis*) has been a subject of much discussion. Non-food items such as wood, glass, plastic, and stones are often ingested incidental to prey capture (Kellogg 1929, Neill 1971). Some items also may be deliberately ingested and retained in the stomach as gastroliths (Brazaitis 1969, Peaker 1969). Cott (1961) believed that gastroliths retained in the stomach of the Nile crocodile (*Crocodilus niloticus*) functioned as ballast that made it easier for the animals to remain submerged. Some writers believed that gastroliths served as grinding tools in the stomach and aided in digestion (Grenard 1991; Neill 1971).

Large amounts of non-food items and other undigestible material such as hair and scales have been found in alligator stomachs and have lead some writers to believe that the items accumulated in the stomach because of the inability of alligators to regurgitate. McIlhenny (1935) believed that everything consumed by *A. mississippiensis* including hair, scales, and feathers, plus wood and other foreign substances, was eventually digested and stated that nothing is rejected through the mouth. Evans (1970) discussed secondary poisoning of *A. mississippiensis* associated with a nutria (*Myocastor coypus*) control program and stated that alligators were unable to regurgitate even if an emetic was included with the poison.

During 1991 and 1992 while conducting an investigation of alligator movement and survival using radio telemetry, I documented regurgitation by *A. mississippiensis*. Radio collars were placed on 140 juvenile *A. mississippiensis* from 1.2–1.5 m total length (TL). The alligators were released in a freshwater marsh ca. 40 km southwest of New Orleans, Louisiana, USA. The radios had a normal signal pulse rate of 55–60 beats per minute and were equipped with a mortality sensor that increased the pulse rate to 100–110 beats per minute if the radio was motionless for a 24-h period.

During the study, mortality signals were received from 26 radios, and the radio collars were located with a directional antennae. All radio collars were recovered, and most were found on the bottoms of shallow ponds. The cause of mortality was cannibalism in 23 of 26 cases. Rootes and Chabreck (1993) reported that cannibalism is common in *A. mississippiensis*, and even adult alligators are occasionally taken as prey by larger alligators. Cannibalism was confirmed by the presence of tooth marks on the plastic portions of the radio units and nutria hair or other material commonly found in alligator stomachs imbedded in the collar. One alligator, 1.2 m TL, with a radio collar attached was recovered from the stomach of a 2.1 m TL male alligator taken during a harvest program in September 1991 (Addison 1993).

In all 23 cases, the radio collar remained in the stomach until digestion of the alligator was complete, then the radio collar was regurgitated. The radio collar could not be excreted with fecal material because of the size of the radio unit. The minimum diameter of the radio unit was 6 cm, which was almost twice the diameter of the small intestine of the largest alligator (3.2 m TL) taken during the harvest program. Radio collars were recovered within 24 h after the mortality signal was received, and no alligator remains were found attached to any of the collars. The amount

of time for the cannibalized alligator to be digested could not be determined because the time of predation was unknown. The radios transmitted at a normal pulse rate within the stomach of the predator, and the mortality sensor was not activated until the radio collar was regurgitated.

Stomachs of some wild alligators contain an abundance of undigestible items (Delany and Abercrombie 1986, Wolfe et al. 1987), and the animals must periodically regurgitate to move material that can not be digested. The ability of *A. mississippiensis* to regurgitate undigestible items is important for keeping intestinal space available for large prey items.

Acknowledgments.—The study was funded by the Louisiana Agricultural Experiment Station, Louisiana Sea Grant College Program, Gheens Foundation Inc., Louisiana Department of Wildlife and Fisheries, The Louisiana Land and Exploration Company, Williams Inc., McIlhenny Company, Avery Island Inc., E. A. McIlhenny Enterprises Inc., and Sweet Lake Land and Oil Company Inc. The assistance of B. Crain, C. Chance, H. Robichaux, R. Moertle, V. Wright, B. Addison, and D. Bossert is greatly appreciated.

Drift fences, pitfall traps, and spotlighting have long been used for amphibian censusing (Campbell and Christman 1982). Hylid frogs, however, can climb out of pitfall traps, climb over drift fences, and may escape visual detection because of their densely vegetated habitat (Dodd 1991, Jones 1986, Greenberg et al. 1994). Anecdotal accounts have reported treefrogs in PVC pipe or bamboo stalks, and we explored the use of PVC pipes for treefrog population assessments. Field studies in 1993 and 1994 addressed the following questions:

1. If a number of pipes were placed in randomly selected wetland habitat sites, would treefrogs use them as resting/hiding spots during the day?
2. Would it be possible to capture enough treefrogs in the PVC pipes to conduct mark-recapture population analysis?
3. Would different species, sizes and age classes of treefrogs use the pipes?
4. What design configuration would maximize trapping success?

Unless otherwise indicated, we used 1 m sections of opaque white PVC pipe (2 cm inside diameter) inserted upright in the ground. Frogs are not restrained or restricted in these pipes; they may climb freely in and out of the hollow opening at the top. During trapping sessions, we checked all pipes daily (between 0700 and 1700 h). When extremely overcast days and/or thick vegetative cover impaired visibility inside the pipe, we ran a flashlight along the outside of the pipe to see if a frog had taken refuge inside.

Trapping was conducted at the Pocosin Lakes National Wildlife Refuge (PLNWR), Washington County, North Carolina, USA, for 21 trapping days per site from June through August, 1993. Paired PVC pipes were placed at 10 m intervals along 250 m of ditch habitat, 1 and 2 m from the water's edge. At three of the 10 sites, we also placed ten 1 m length, 5 cm inside diameter, PVC pipes. We also surveyed each site twice per trapping session for nighttime frog calling. Night surveys entailed visiting each site (at least 30 minutes after sunset) for a 10 minute period. Each calling species was assigned a category of abundance as single (one individual), few (at least 2 but no more than 3), several (more than 3 individuals, with each call distinguishable from the other), or abundant (chorus; so many frogs calling that individual calls could not be distinguished).

From June through September, 1994, we conducted 12 trapping sessions totaling 33 trapping days at each of 9 sites. Pipes were set in an 80 point grid (9x9, excluding the middle point) around a round cattle trough (which served as an artificial breeding pool). Points were 1 m apart, with 2 pipes placed at each point. Along the ditch nearest to each trough (within 100 m), paired pipes were set at 1 m intervals for 25 m. Because we heard *H. femoralis* chorusing from a small natural breeding pond in June, we also set 50 pipes 1 m apart along the edge of this pond, and checked these pipes for 10 2-day trapping sessions.

In 1993, 62 individuals of 3 species (*Hyla cinerea*, *H. femoralis*, and *H. squirella*) were found in the PVC pipes. All frogs were of adult size (21 to 51 mm svl). Most captures occurred in the 2 cm diameter PVC, with only 2 of 133 total captures in the 5 cm diameter PVC. A definite relationship exists between call survey and PVC trap results. Where we heard a species calling, we caught that species in the pipes.

In 1994, we captured 78 individual *H. femoralis*, with 210 recaptures. We also caught newly emerged *H. femoralis* (8 mm SVL) and *Pseudacris ocularis* (15 mm SVL) in PVC pipes. We trapped between zero and six individuals per trough site per day, yet consistently trapped between four and eight frogs at the natural breeding pond site. After determining whether the pipe was in vegetative cover, partial cover, or no cover, we registered no significant difference in capture rates among the three categories of cover ($P<0.05$; $X^2=3.75$). Captures occurred in pipes without vegetative cover 109 times, in partially covered pipes 104 times, and in pipes covered by vegetation 70 times.

Using PVC pipes to trap adult and newly-emerged treefrogs for quantitative field studies appears to be a useful way to monitor hylids, and possibly other frogs as well. Site placement was important to our study. The only trough site where frogs were neither captured nor heard calling was located within 500 m of the natural breeding pond. However, hylids occupied and were trapped successfully at artificial breeding pool sites >1500 m from this natural pond. When designing field studies, the following criteria should be considered:

1. Pipes should be arranged near natural or artificial breeding areas.

2. Distances between pipes at small ponds or artificial pools should be small. Pipes may be placed further apart in large wetlands where breeding activity is more widespread. We recommend a 1–5 m interval to facilitate trapping and recapture success at small sites, and a 10 m (or more) interval at large sites.

3. Trapping sessions should be 2 or 3 days. Longer sessions increase site disruption, do not add significant numbers of individuals to the data set, and are more likely violate the assumption of a "closed population" necessary for some types of analyses.

Using PVC pipes to "trap" treefrogs eliminates trap mortality and allows movement for breeding and foraging activity. This trapping method is inexpensive and easy to use, set up and store. By using PVC pipes to trap treefrogs, quantitative field studies may serve to supplement call surveys, to assess effects of experimental treatments (e.g., pesticide applications), and to monitor population trends.

Acknowledgments.—We thank Cheryl Kelley and Kristen Lehman for their assistance in trapping and David Kitts for sharing his general knowledge of habitat on PLNWR and help in site selection. Many thanks go to Herman Berkhoff, Joe Phelps, and Paris Trail for recounting their experiences of finding treefrogs in pipes and bamboo. Kenneth H. Pollock, George Barthalmus, and Harold Heatwole provided useful guidance for the study design. Harold Heatwole and James D. Nichols kindly reviewed this manuscript.

Evaluation of a Radio-Belt for Ranid Frogs

GALEN B. RATHBUN

and

THOMAS G. MURPHEY

Although biologists have developed numerous ways of marking anurans (Heyer et al. 1994), there are relatively few reports regarding the performance of radio-tags attached successfully to frogs and toads (e.g., van Gelder et al. 1986). Because of the delicate nature of frog skin, most efforts to attach radios have involved harness devices made of plastic (silicon) tubing (Jon Loman, pers. comm.) or latex rubber straps and bands (Richards et al. 1994). We developed a simple waist-belt made of aluminum ball or beaded chain (size #3, Ball Chain Manufacturing Co., 471 South Fulton Avenue, Mt. Vernon, New York 10550, USA; tel. 914/664-7500; or Bead Industries, 110 Mt. Grove Street, Bridgeport, Connecticut 06605, USA; tel. 203/334-4124) to attach radio transmitters to free-ranging, adult California red-legged frogs (*Rana aurora draytonii*). The chain lacks sharp edges, is flexible, and rolls or slides easily over the skin, thus conforming to the contour of the frog with little friction.

We use gloss black enamel spray paint to reduce reflection of the shiny chain; flexibility is restored with gentle twisting after the paint is dry. Devcon two-ton epoxy serves to cement a #3 aluminum chain connector to the tip of a radio transmitter (model BD-2G, 8 mm wide x 6 mm deep x 17 mm long, 12 cm long whip antenna, 1.8 g without attachment, battery life about 140 days; Holohil Systems Ltd., 112 John Cavanagh Rd., Carp, Ontario, Canada K0A 1L0, tel. 613/839-0676). To accomplish this, we file a small hole in the back of the connector, clean the connector and transmitter attachment site with fine steel wool, and then apply epoxy and allow it to flow through the hole, being careful to prevent the inside of the connector from being fouled. We apply the epoxy in two stages; a small amount to position the connector followed by a larger amount to ensure a strong bond. Our radio-tag weighs about 2.0 g, but smaller assemblies weighing as little as 1.0 g (with a battery life of about 20 days) can be fabricated.

Two people are needed to radio-tag a frog: one to hold the animal, the second to fit the belt. To obtain a good fit, we slip representative chain/connector belts of different sizes, each labeled with the number of balls in the chain, over the extended rear legs of a

frog until we find the one that fits best. A perfect fit occurs when the belt slides snugly over the extended legs, and slightly compresses the upper leg muscles as it slips onto the waist. Once the belt of best fit is determined, the correct number of balls is cut from a painted length of chain, and a transmitter is attached. The fully assembled radio-belt is then slipped over the extended legs, making sure that the smoothest side of the transmitter faces the frog's skin (Fig. 1). The tagging process, from capture to release, takes about five minutes.

We release the frogs with the transmitter riding on the dorsum, but when they are recaptured the transmitter is often on the ventrum; transmitter position does not appear to affect the frogs. Because of corrosion and wear, a new chain is always fitted when frogs are recaptured for transmitter replacement. When the physical condition of a frog changes due to an increase or decrease in rear leg muscle mass, one or two balls are added to, or subtracted from, the belt to achieve an optimal fit. Belts too loose are sometimes shed, while those too tight sometimes cause indentations and small sores on the skin.

With an "H"-style receiving antenna (Telonics, Mesa, Arizona 85204, USA) connected to our radio receiver (model TX1000S, Wildlife Materials, Carbondale, Illinois 62901, USA), and under near-ideal field conditions, we routinely obtained a signal range of about 100 m when a frog was on land. Below clear, fresh water we usually received a signal from a distance of about 5 m.

We deployed 89 transmitters on 47 (24 males and 23 females) individual *Rana aurora draytonii* in coastal arroyos and lagoons of northern San Luis Obispo County, California, USA, from July 1992 through November 1995. Snout-urostyle lengths of these individuals ranged from 83 mm to 127 mm (three individuals were in the 80–89 mm size-class, 15 individuals in each of the 90–99 mm and 100–109 mm classes, 12 in the 110–119 mm class, and two in the 120–129 mm range). Twenty-two individuals were tagged once, 12 twice, 7 three times, 5 four times, and 1 five times. The 47 frogs were radio-tagged a total of 4155 days with a mean of 88.4 days/individual (SD = 73.2, range = 13–296).

We found about six cases where small (1–2 mm diam) skin sores developed from the chain belt passing over the sides of the waist. Early in the study we maintained a captive frog with skin sores; healing without a belt attached took two days. When subsequent cases of skin sores arose, we added one or two balls to the replacement chain and released the frogs. We recaptured some of these individuals and found that their wounds had healed in less than 14 days. We also assessed weight change between initial radio-tagging and recapture in 16 frogs. Two males and a female lost 2.0, 4.0, and 5.0 g after 42, 63, and 60 days, respectively. Average weight loss was 3.0% of mean initial weight. Five males and eight non-gravid females gained an average of 7.9 g over a mean of 61.6 days (SD = 19.5, range = 21–118). The average weight gain was 7.2% of their mean initial weight. These data suggest that the radio-belt did not significantly affect the frogs' weight.

Transmitter failure.—We lost radio contact with 23 frogs before the predicted exhaustion of their transmitter batteries. We recaptured seven of these with intact radio-belts, but dead transmitters. Water leakage probably caused the failure of some of these radios. The fate of the 16 missing radio-belts or frogs is unknown—the radio-belts may have been shed in salty lagoon water and lost due to signal attenuation, or the frogs may have left the study area after being ingested by herons or egrets. It is also possible that the frogs evaded recapture and are still in the population carrying failed transmitters. We believe it is unlikely that they traveled beyond the study area on their own.

Belt loss.—We recovered 24 functioning transmitters that had been shed by frogs; the belts failed in four of these early in the study while we were experimenting with different types of epoxy and chain. The remaining 20 radio-belts were recovered intact; some had tooth marks, suggesting raccoons or some other predator had removed the frogs from their belts. One intact radio-belt was found in a tree on a red-shouldered hawk roost. However, not all belt losses were due to predation; ten of the 23 frogs, identified by passive integrated transponder (PIT) tags, were recaptured. We speculate that these frogs shed their belts over their extended rear legs while moving through dense vegetation.

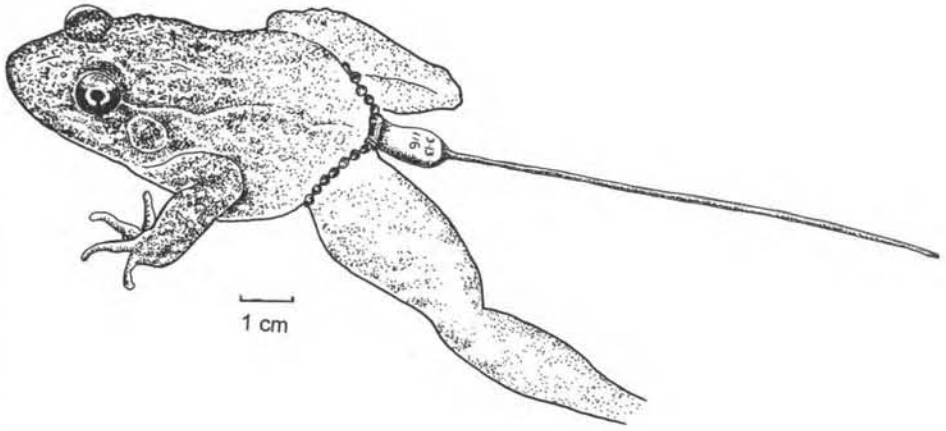

FIG. 1. Beaded chain radio-belt applied to an adult *Rana aurora draytonii*.

In any species, attaching radios with collars or belts has its risks (see Chapter 5 in Kenward 1987). During our study, we found four radio-tagged frogs dead in February and March when bulrushes send new growth up through the water column. In two cases, the frogs probably drowned when underwater bulrush shoots became threaded between the belt and the frog. We suspect the same happened to a third frog, but it was too decomposed to determine cause of death. The fourth frog had a broken mandible associated with a deep cut, suggesting that its death was unrelated to the radio-tag assembly. Despite these mortalities, we believe that attaching radios to large ranid frogs using a ball or beaded chain belt is relatively safe and effective, and represents an improvement over other radio-tagging techniques reported in the literature.

Acknowledgments.—We are grateful for the support of the California Department of Parks and Recreation and the California Department of Transportation. We thank San Simeon State Park and the Cambria Com-

munity Services District for permission to work on their properties. This work was done under permit from the California Department of Fish and Game. We appreciated the cooperation of the Ball Chain Manufacturing Company and Bead Industries. Fred Anderka of Holohil Systems provided helpful technical advice. We benefited from the comments of several reviewers of this paper, especially Norman J. Scott, Jr. and Samuel S. Sweet.

Note added in press.—We have confirmed that significant radio-belt loss and frog mortality may occur in bulrushes. In late September 1996, we radio-belted eight frogs in a pond dominated with bulrushes. Within 16 days one frog was lost to natural predation, two shed their belts among bulrush stems, and two died from entanglement on bulrush shoots. We removed the radio-belts from the three remaining frogs.

The "Skink Scooper:" A Device for Catching Leaf Litter Skinks

BAYARD H. BRATTSTROM
Department of Biology, California State University
Fullerton, California 92634, USA

In a study of a community of small, leaf litter and grass dwelling skinks in an Australian sclerophyll forest (Brattstrom, *in prep.*), my success at capturing live skinks by hand was only about 15%. Because frustration often leads to creative solutions, I discovered a method that raised my capture success for these small skinks to 95%.

The "Skink Scooper" is a square or rectangular, tan or brown, plastic waste basket or garbage can; brighter colors may startle the skinks. Square plastic pails with handles can be substituted. Baskets should have sufficient lips around them to facilitate holding. When a skink is sighted, the basket is held 15–30 cm away from the skink. With the other hand, leaf litter and, hopefully, the skink are brushed quickly into the basket (Fig. 1); then leaves can be removed carefully, leaving the skink at the bottom. Transfer the skink directly into a bag or pick it up in your hands. Not only was this method more effective than hand capture, but fewer specimens wound up with broken tails.

The basket technique was also used against small cliffs in gullies to catch one species (*Carlia storri*) that ran along the surface of the cliff. This species would drop to the ground or escape over the top edge of the cliff. By placing the basket below the lizard, and gently brushing the lizard downward, the lizard, more often than not, fell into the basket. With this basket technique, I was able to catch hundreds of skinks an hour where only a few captures an hour were possible with the hand grab.

Baskets can also be used to catch falling geckos; arboreal lizards (such as *Diporiphora australis*) that feed in small shrubs and drop to the ground to escape can also be caught in the basket during mid-drop.

and

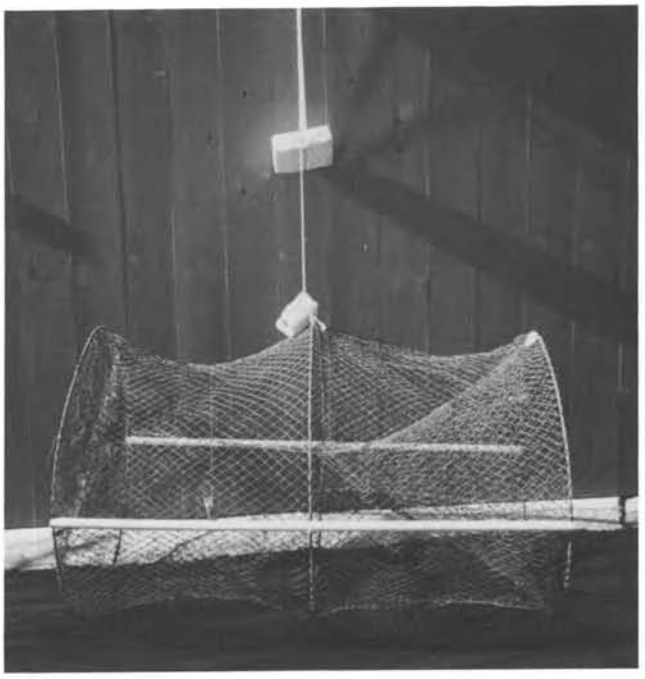
ARTHUR GEORGES
Applied Ecology Research Group and Centre for Freshwater Ecology
University of Canberra, P.O. Box 1
Belconnen, A.C.T. 2616, Australia
e-mail: georges@aerg.canberra.edu.au

Installing commercially available turtle hoop traps to steel fence posts driven into the substrate works reasonably well for shallow water, but is cumbersome and does not allow deep water sets. Legler (1960) described the use of a homemade funnel trap supported by four aluminum hoops; long wooden dowels (one on either side) with screw hooks kept his traps erect. Legler's technique has been used successfully in Australia (Georges, unpubl.), and we adapted it for setting hoop traps in deep water.

Inexpensive 3/4 inch (1.9 cm) white PVC pressure pipe was first cut to length (approx. 5 cm longer than the trap) and then a 1.5 cm deep notch was cut and filed into each end to grip the hoops of the trap. With the pipe slightly longer than the trap, tension (evidenced by a slight bowing of the pipe) helped keep the pipe tightly coupled to the trap ends. Once in place, the pipe on either side was secured to the center hoop by a nylon cable tie. This tie kept the pipes positioned during trap erection and also prevented their loss if the notched ends slipped off the hoops; the pipe was slipped out of the cable tie during disassembly and in-

serted back through it during reassembly. A refinement of pipe attachment which further reduces accidental pipe loss involves pipe insertion through the end mesh of the trap and the tie so that the entire strut is located inside the trap (R. Saumure, pers. comm.). Finally, braided nylon cord was tied firmly to the top of the center hoop and a short way (ca. 5 cm) up this cord a piece of styrofoam insulation (15 x 8 x 8 cm) was tied to keep these round-bottomed traps upright. A 20 x 15x 10 cm piece of foam was tied to the top (surface) end of the cord to serve as a buoy for trap retrieval. White pipe made traps more visible underwater and allowed us to adjust trap position.

With these modifications (Fig. 1), the standard commercial trap can be set up and taken down quickly. If traps are set at depths preventing entrapped turtles access to air, they must be tended on a frequent schedule to prevent drowning. The maximum permissible interval between trap checks will depend on prevailing temperature, but for most summer applications traps should not be left unattended for more than 90 minutes.



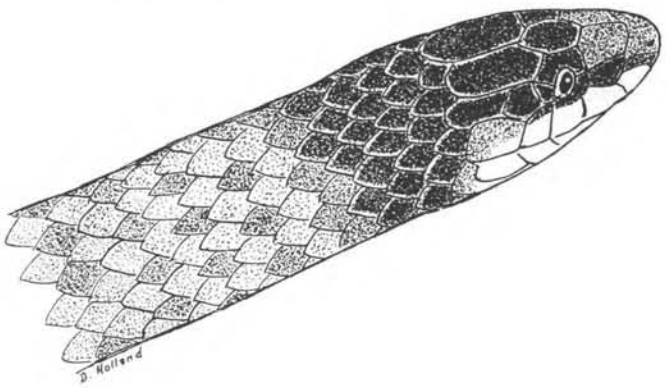


FIG. 1. Aquatic funnel trap modified for placement in deep water.

Effectiveness of Aquatic Funnel Traps for Sampling Amphibian Larvae

GEOFFREY R. SMITH*
and
JESSICA E. RETTIG
Kellogg Biological Station, 3700 East Gull Lake Drive
Hickory Corners, Michigan 49060, USA

Present Address: Biology Department, Earlham College, Richmond, Indiana 47374, USA. E-mail: smithge@earlham.edu

As increased attention is focused on studying amphibian populations, techniques that allow for rapid assessment of amphibian population status are needed (see Heyer et al. 1994). The use of aquatic funnel traps for the collection of amphibian larvae (Calef 1973; Shaffer et al. 1994) and adults (Griffiths 1985; Richter 1995) has been suggested. In this note, we describe three designs for aquatic funnel traps and present observations on the effectiveness of each.

DESIGN 1: This trap is made from a section of PVC pipe (5 cm diameter, 25–30 cm long), two plastic funnels of half-pint (4 oz) capacity, and a rubber band of appropriate length and width. The funnels are inserted into each end of the PVC pipe and held in place by the rubber band (Fig. 1). Traps are secured by attaching them to stakes driven into the ground. Funnel ends may become dislodged overnight because of rubberband slipping, but we solved this problem by filing notches into the funnels. Notches allow a much tighter fit of funnel ends to PVC pipe. Another solution is to permanently attach a funnel to one end and allow only one funnel to be removable. The cost of this trap is about US$2.00–4.00.

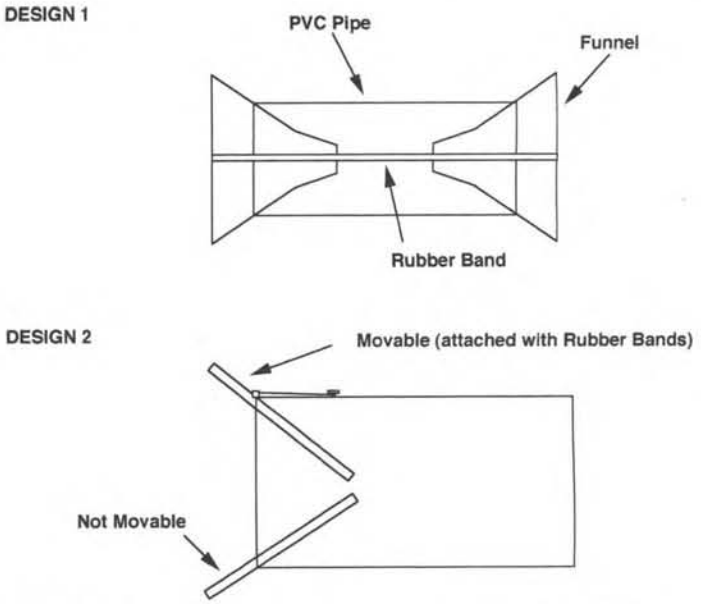

FIG. 1. Two aquatic funnel trap designs used for capturing amphibian larvae. See text for details.

DESIGN 2: Actually an ichthyoplankton sampling device for capturing fish larvae (Werner 1968), this trap resembles terrestrial funnel traps except that only one end is open, and it is made of 1/8 in. thick, clear acrylic (Fig. 1). The dimensions of our trap were 30.5 cm x 15.2 cm x 15.2 cm, with the guides being 45.6 cm

x 15.2 cm. We used IPS Weld-On #16 Cement for Acrylic Sheet (IPS Corporation, Gardena, California, USA) to glue the trap together. One of the two "guides" is left moveable (to facilitate removal of larvae) and should be able to be held in place by friction and a small rubberband. These traps are attached to anchors and floats and can be placed anywhere in the water column. The cost is US$10.00–15.00 per trap (depending on trap size and type of materials used).

DESIGN 3: This design requires a 2-liter plastic soft drink bottle and waterproof tape and is nearly identical to the design described by Griffiths (1985). The spout end of the bottle is cut off, reversed to form a funnel, and reattached to the bottle with tape. Holes are punched into the bottle to allow water to enter, and facilitate sinking. Traps were attached to floats. The cost of this trap would be < US$1.00.

We tested the capture ability of each trap at the Kellogg Biological Station Experimental Pond complex, placing traps in the ponds for a specific period of time, often 12 h overnight (2000–0800 h EDT). DESIGN 2 and 3 traps were placed in the center of the ponds at depths between 30 and 50 cm (1–2 m above the pond bottom), whereas DESIGN 1 traps were generally placed 1–2 m from the pond edge at a depth of 20–40 cm (resting on pond bottom).

All traps captured at least one tadpole, and trap effectiveness appeared to depend on time of year; fewer tadpoles were captured late in the season (Table 1). The most effective (numbers of tadpoles caught) were DESIGN 1 traps placed in the shallows, followed by DESIGN 2 traps placed in the middle of the ponds. DESIGN 3 traps did not catch many tadpoles, but they were tested late in the season, and their effectiveness may have been underestimated.

TABLE 1. Number of tadpoles caught per trap for each of three trap designs. Individual trap results separated by commas. Dash means that no trap of that type was placed. X indicates a failed trap.

	DESIGN 1		DESIGN 2		DESIGN 3	
	w/light	w/o light	w/light	w/o light	w/light	w/o light
June 28	51, 0	0, 0	14, 15	—	—	—
July 3	17, 0, X	1, 0, 0	—	—	—	—
July 5	1, 0, X	1, 0, X	—	—	—	—
July 10	—	—	3	1	1, 2	0

Neither DESIGN 1 nor DESIGN 2 was effective for catching aquatic adult red-spotted newts (*Notophthalmus viridescens*).

Glow sticks greatly increased the effectiveness of DESIGN 1 traps. When lighted and unlighted DESIGN 1 traps were placed within 2 m of one another, the lighted trap caught several tadpoles whereas the unlighted trap caught none. Lightsticks also increased captures in DESIGN 2 and DESIGN 3 traps. Care should be taken to ensure non-toxic light sources are used. Lightsticks available commercially are rather expensive (≈ US$2.00 each) and cost may limit the number of traps that can be used per night, or the number of nights that lightsticks can be used.

Our results suggest that these trap designs may be effective for collecting tadpoles to study natural growth rates. Placing traps in several habitat types and microhabitats would allow for the study of habitat and microhabitat use patterns by amphibian larvae in natural aquatic systems. We have no data on how effective these traps are at quickly assessing amphibian diversity (only one species was captured: *Rana catesbeiana*).

Ease of construction, low cost, and repeatability of construction render these funnel traps an excellent sampling technique for aquatic amphibian larvae.

Acknowledgments.—The comments of S. Busack greatly improved the manuscript. We thank G. Mittelbach for allowing us access to the KBS Experimental Pond Complex. Fish larvae trap construction and J.E.R. were supported by an NSF Research Training Grant at the Kellogg Biological Station, Michigan State University.

e-mail (EG): egodinez@servidor.unam.mx

Heloderma horridum has been succesfully maintained in captivity for decades. Captive specimens have been recorded as early as 1908 (Perry-Richardson and Ivanyi 1995), while captive reproduction was first reported in 1982 (Anstanding 1988). A review of the *Inventory of Live Reptiles and Amphibians in Captivity* (Slavens 1984–1994) revealed that over 50 institutions housed this species, with over 150 specimens represented. For this same period, only 18 reproductions were reported. Perry-Richardson and Ivanyi (1995) list 291 specimens maintained in captivity since 1908. A total of 40 reproductions are listed begining in 1983, with 111 hatchlings produced. We are documenting here the first captive reproduction of *Heloderma horridum* in México.

The "Laboratorio de Herpetología–Vivario" (located on the UNAM campus Iztacala in México City) received two *Heloderma horridum* from different sources in 1985. The sexes of both animals were unknown. On 5 August 1985 we observed courtship behavior and mating for the first time. No further activity was observed until a single egg was laid on 17 October 1986. It was artificially incubated until it began to decompose, when it was discarded. After this, no reproductive activity was observed for another four years.

TABLE 1. Hatching data for *Heloderma horridum* offspring. NA = natural absorption of yolk sac; C = yolk sac removed.

Hatch Date	Yolk Sac Presence	Hatch Weight (grams)	Juvenile Weight November 1995
November 29	+ (NA)	40.50	141.8
November 29	+ (NA)	42.16	161.1
December 02	+ (C)	21.40	124.6
December 02	—	43.11	131.1
December 02	+ (C)	41.41	133.5
December 06	+ (C)	37.26	—
December 08	+ (C)	42.19	—
December 10	+ (C)	—	—
December 15	+ (C)	27.69	—

The animals were hibernated during the winter of 1990–1991 for three months at a temperature of 23–26°C, a technique we have continued to use. On 24 May 1991 copulation was again observed. Motile sperm was found on the enclosure substrate. Courtship and mating were observed for five days until the pair were separated to avoid injury to the female. Three months later the pair were reintroduced, and courtship was again observed on 17 June 1992. No oviposition occurred from these matings.

From 26–28 April 1993, courtship and mating were again observed. On 26 July 1993, fifteen eggs were found buried in a sand nest at a depth of 18 cm. The eggs were removed from the enclosure, weighed (range 38.3–44.0 g), and artificially incubated at 29°C and 95–100% relative humidity. After six months the eggs showed no signs of development and were opened. There was no apparent embryonic development.

In April 1994 courtship was again observed. On 3 July 1994, eleven eggs were found on top of the soil in a corner of the enclosure. The eggs were removed and incubated at 29°C, 90–95% relative humidity in plastic boxes containing agrolite. Each box was opened daily and aired, but the eggs were not moved from their original position. Two eggs began to collapse and turned a yellowish color; when opened, one showed no embryonic development while the other had an advanced dead embryo. On 29 November the first hatchling emerged. By 15 December nine babies had emerged from the eggs (see Table 1 for data). Six of the young had trouble absorbing their yolk sac. They started showing signs of decline so the yolk sacs were removed with catgut. Four of these individuals died within the following two months. Necropsy of these four animals revealed that death was due to extensive septicemia originating in the yolk sac. The five surviving individuals, including two which had yolk sacs removed, are a year old at the time of writing, and are doing well.

There are few observations of varanid egg deposition recorded, even in detailed studies of reproduction of individual species (e.g., Carter 1992; Cowles 1930). The few observations where egg deposition has been seen, have largely been made during daylight hours. Bom and Bom (1989) observed captive *Varanus exanthematicus microstictus* nesting in the morning. A number of largely anecdotal records of varanids nesting are also presumed to be diurnal,

given the lack of any specific reference to the observation being carried out at night (e.g., Auffenberg 1983; Biswas and Kar 1981; Branch and Erasmus 1982; Deraniyagala 1957; Fleay 1960; Gaulke 1989; Riley et al. 1985; Smith 1931; Worrell 1963).

Varanid lizards are normally considered to be diurnal (Cogger et al. 1983) although some nocturnal activity, exclusively associated with feeding, has been recorded (Greer 1989). Christian (1977) recorded *V. glebopalma* foraging for food during the first couple of hours after sunset while Fyfe (1979, 1980) recorded *V. tristis* feeding near lights outside a building. A recent record of nocturnal activity of *V. spenceri* by Valentic (1995) may be due to retreat site disturbance.

Nocturnal nesting by captive varanids has been reported in several species: *V. varius* (Horn 1991), *V. exanthematicus* (Bayless and Huffaker 1992; Bayless and Reynolds 1992; Bayless 1994), and *V. albigularis* (Duinen 1983). Horn (pers. comm.) has observed nocturnal nesting in *V. varius* on three other occasions, as well as crepuscular laying in *V. salvator* and *V. mertensi*.

In this note, we report observations of nocturnal nesting in four species of captive varanids (*V. giganteus, V. indicus, V. keithhornei* Wells and Wellington 1985 (= *V. teriae* Sprackland 1991), *V. mertensi*) at the Queensland Reptile and Fauna Park, Beerwah (pers. obs.). Irwin et al. (in press) developed a strategy for the detection of egg-laying based on feeding behavior. This involves restricting food to suspected gravid females so that they are left hungry enough to eat a similar sized food portion the following day. As the animal approached the time of egg-deposition, her interest in food decreases with a corresponding decline in the amount being eaten. This has enabled a more effective targeting of observations and has resulted in multiple instances where nocturnal egg deposition has been witnessed. All nocturnal nesting episodes have been confirmed by direct observation or collection of eggs for incubation the next morning. One instance of nocturnal nesting by *V. giganteus* has been videotaped.

The four species that have been observed nesting at night have very different ecologies and distributions. *Varanus giganteus* frequents rocky outcrops, escarpments, and dry sandy country (Horn and Visser 1988; King et al. 1989; Pianka 1982); *V. indicus*, the mangrove and closed forests of northern Australia (Cogger et al. 1983); *V. keithhornei*, the canopy of forests in Cape York (Irwin 1994); and *V. mertensi* in a variety of habitats across northern Australia (Schürer and Horn 1976; Shine 1986). Nesting activities for these four species has only been observed at night. Four other species of varanids (*V. acanthurus, V. gouldii, V. spenceri,* and *V. varius*), which also have bred at the Park, have not been observed nesting at night.

This does not mean that nocturnal nesting by this second group of species does not occur. Rather, nesting activities, whether diurnal or nocturnal, are difficult to observe owing to cryptic behaviors, and can only be confirmed by the procedure outlined in Irwin et al. (in press).

While three of the varanids that nested at night are on public display, *V. keithhornei* specimens are permanently off-display and therefore their nocturnal nesting is not an aberrant response to human disturbance or interaction. This is further supported by the fact that courtship, mating, and agonistic behaviors are all undertaken during daylight hours. Given that all varanids are kept in open pits (except *V. keithhornei*, which is in a temperature controlled environment), and that the nesting has occurred in many different months and under diverse climatic conditions, it is unlikely that the nocturnal nestings have been triggered by environmental stimuli.

The recognition that *V. varius* nests both diurnally and nocturnally bears careful consideration. King and Green (1993) suggest that "egg-laying occupies a few hours." Horn (pers. comm.) has observed some varanids taking over ten hours to deposit a clutch. These extended laying periods may be associated with animals that are either infertile or in poor health (Horn, pers. comm.). Consequently, nocturnal nesting may occur as a result of an extended egg-deposition begun during the day. Alternatively, diurnal nesting may occur in a nocturnal-nesting species engaging in an extended nocturnal egg-deposition episode.

Acknowledgments.—We thank Georg Horn and Mark Bayless for their assistance in the preparation of this note.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in volume 27, number 2 (June 1996).

CAUDATA

AMBYSTOMA CALIFORNIENSE (California Tiger Salamander). **BURROWING ABILITY.** It is assumed that ambystomatid salamanders are generally poor burrowers and rely upon accessible rodent burrows for estivation habitats (see Semlitsch 1983. Can. J. Zool. 61:616–620). During an 18 February 1996 nocturnal survey for adult California tiger salamanders at a site ca. 2.25 km southeast of Calero Reservoir, Santa Clara County, California, USA, I observed an adult male *Ambystoma californiense* successfully dig through the plugged entrance of a valley pocket gopher (*Thomomys bottae*) burrow. The observation was made on a rainy night between 2131 and 2300 h. The salamander was first observed with its muddied head inserted into a pocket gopher mound. The salamander was then removed, examined, sexed, and placed back in its original position. Subsequent examinations at 15-min intervals revealed the salamander was able to successfully find the burrow entrance and then dig through the mound plug into the pocket gopher burrow. The salamander's digging efforts were aided by a constant steady rainfall, which materially softened the exposed soil of the pocket gopher mound. This observation is significant because it indicates that California tiger salamanders have the ability to burrow out of or into normally closed pocket gopher burrows given sufficiently moist soil conditions. Thus, potential estivation habitat for this salamander is not limited by the surface activities of California ground squirrels (*Spermophilus beecheyi*) or valley pocket gophers in keeping their burrows open at critical times of the year.

My thanks to Norman J. Scott, Jr. for reviewing the manuscript. Permits to conduct salamander surveys were provided by the California Department of Fish and Game.

Submitted by **MARK R. JENNINGS**, National Biological Service, California Science Center, Piedras Blancas Field Station, P.O. Box 70, San Simeon, California 93452-0070, USA, and Research Associate, Department of Herpetology, Califomia Academy of Sciences, Golden Gate Park, San Francisco, Califomia 94118-9961, USA.

PLETHODON CINEREUS (Redback Salamander). **PREDATION.** On 5 June 1993, we observed a *Turdus migratorius* (American robin) at the Mountain Lake Biological Station, Giles Co., Virginia, USA, with an adult *P. cinereus* in its beak. The bird flew ca. 30 m, settled to the ground, and began to peck vigorously at the wiggling, autotomized tail of the salamander. The salamander was less than a meter from the bird. When we approached, the bird flew off. The salamander died within the hour, presumably from injuries suffered while being carried by the bird. Although our intrusion prevented us from observing the culmination of the event, the bird was clearly distracted by the autotomized tail.

Avian predation is not believed to be an important factor in the population dynamics of terrestrial salamanders (Hairston 1980. Am. Nat. 115:354–366). With the exception of the eastern hermit thrush (*Hyloccichla guttata faxoni*), which has been observed feeding *P. cinereus* to its young, salamanders are not mentioned in the diets of thrashers, towhees, and thrushes that forage in the forest litter (Bent. 1964. Life Histories of North American Thrushes, Kinglets and their Allies. Dover Publ., Inc., New York; Hairston 1980, *op. cit.*).

Submitted by **THOMAS L. D. FENSTER**, 4103 Sheridan Street, University Park, Maryland 20781, USA, and Mountain Lake Biological Station, Route 1, Box 105a, Pembroke, Virginia, USA; and **CHARLES B. FENSTER**, Department of Plant Biology, University of Maryland, College Park, Maryland 20742-5815, USA.

PLETHODON DUNNI (Dunn's Salamander). **CANNIBALISM.** Cannibalism has been documented in many amphibians, including several families of salamanders (Crump 1992. *In* Elgar and Crespi, eds. Cannibalism: Ecology and Evolution Among Diverse Taxa, pp. 256–276. Oxford Univ. Press, New York). However, relatively little is known about cannibalism in terrestrial amphibians. Only anecdotal reports of cannibalism in *P. dunni* exist (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. of Idaho Press, Moscow, Idaho. 332 pp.). Herein we report cannibalism of juvenile *P. dunni* by adults under natural conditions.

During Fall 1995 at Fall Creek (Lincoln Co., Oregon, USA, 10 km W Alsea; 360 m) in the Coast Range we stomach flushed 21 adult *P. dunni* and found juvenile *P. dunni* in two (9.5%) gravid females . The first female (SVL 54.5 mm, mass 5.1 g, collected 14 October 1995) regurgitated a juvenile conspecific (SVL 20.6 mm, mass 0.12 g). The second female (SVL 71.4 mm, mass 5.64 g, collected 11 December 1995) also regurgitated a juvenile (SVL 28.5 mm, mass 0.51 g).

The large size difference that exists between juvenile and adult *P. dunni* may promote cannibalism . Cannibalistic individuals may find that conspecifics provide a food source that is easily assimilated and may increase growth and enhance reproduction.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in volume 27, number 2 (June 1996).

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). **COMMUNAL NESTING.** Communal nesting by marbled salamanders is infrequent and typically includes fewer than three females. Of 72 nests observed by Graham (1971. Ph.D. Diss., Rutgers Univ.), only nine (12.5%) were communal and included the clutches of two (N = 7), three (N = 1), and seven (N = 1) females; 16 (5.5%) of 292 nests observed by Petranka (1990. J. Herpetol. 24:229–234) contained eggs of two females and three (1.0%) contained eggs of three females.

I observed communal nesting by marbled salamanders on 6 and 12 October 1995 at a semi-permanent, 15 x 19 m, man-made pond in the Hoosier National Forest, Crawford County, Indiana, USA. The pond is within a second-growth pine-hardwood forest. Approximately 15% of the clay-mud base is sparsely covered with herbaceous vegetation; the remainder is bare mud sparsely covered with fallen leaves. When these observations were made, half the basin was covered with water, leaving a 2 m wide band of mud above the water level. Nests were considered communal if clutches in adjacent depressions constructed by females were indistinguishable, the number of eggs was two or more times greater than the average of single nests (mean = 110 eggs), or nests contained eggs in varying stages of development.

Of 29 nests found, 12 (41.4%) were single-female nests containing 51–169 eggs, nine (31.0%) contained 163–319 eggs of two females, four (13.8%) contained 323–413 eggs of three females, one (3.4%) contained 514 eggs of four females, two (6.9%) contained 771 and 796 eggs of seven females, and one (3.4%) contained 1813 eggs of 16 females.

Marbled salamanders typically nest beneath cover such as leaf litter, logs, roots, rocks, or vegetation (Graham, *op. cit.*; Jackson et al. 1989. Can J. Zool. 67:2277–2281; Noble and Brady 1933. Zoologica 11:89–132; Petranka, *op. cit.),* or in crayfish or small mammal tunnels (King 1935. Ohio J. Sci. 35:4–15). Nests are generally concentrated in areas with high total cover (Jackson et al., *op. cit.).* The Crawford County pond is devoid of accumulated leaf litter from previous years except at the basin edge. Only four nests were found in this zone, the remainder were located at middle or lower elevations where leaf litter was absent when females oviposited. Females may have been forced to nest communally due to the paucity of cover. Most nests were partially or completely exposed until covered with freshly fallen leaves. Although females may have oviposited simultaneously in some nests, embryos in several communal nests ranged from Harrison stage 19 to 37 (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York, pp. 131–132), suggesting that later arriving females may have used eggs of preceding females as cover.

Only three nests (10%), all communal, had a single female in attendance. Nest attendance, which increases embryo survival, is typically much higher than that observed at the Crawford County pond (e.g., 87.4%, Jackson et al., *op. cit.;* 75.5%, Petranka, *op. cit.).* Estimates of embryo mortality in five communal nests ranged from 0–90%. The largest communal nest was exposed to direct sunlight for one hour each morning. On 12 October, temperatures in this nest varied from 22°C at the bottom to 27°C at the top immediately after exposure to the sun, suggesting that high temperatures may have contributed to high (ca. 90%) embryo mortality (Anderson 1972. Herpetologica 28:126–130).

I thank J. Sean Doody for commenting on the manuscript.

Submitted by **JOHN G. PALIS**, Rural Route 1, Box 258, Tell City, Indiana 47586, USA.

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). **COLORATION.** A mottled *Amphiuma tridactylum* was brought to Northeast Louisiana University Museum of Zoology by an anonymous person during summer 1988. The specimen (NLU 70638) measured 34 cm SVL, pigmentation varied from dark brown to black circular blotches of assorted sizes with a leucistic body color (Fig. 1). The origin of the specimen is unknown, however it is believed to have been collected in Louisiana.

FIG. 1. Adult mottled (left) and albino (right) *Amphiuma tridactylum* from Louisiana.

A second specimen, an albino, was collected 20 July 1992 in a ditch approximately 8 rd km S of Thibodaux, in Lafourche Parish, Louisiana, USA, by Terry P. Guidroz. This specimen (NLU 70488), 243 cm SVL, lacks all pigmentation except for the coloration of its blood vessels and pink eyes (Fig. 1).

Although albinism has been reported for this species (Cagle 1947. Copeia 1947:210), and in the family Amphiumidae (Palmer and Braswell 1980. Brimleyana 3:49–51) and in other amphibians (Dyrkacz 1981. SSAR Herpetol. Circ. 11:131), this is the first published account of mottled coloration and second report of albinism for this species.

Submitted by **STEVEN G. GEORGE**, U.S Army Engineer Waterways Experiment Station ER-A Vicksburg, Mississippi 39180, USA.

ANEIDES LUGUBRIS (Arboreal Salamander). **PREDATION.** On 7 February 1994 at ca. 1130 h PST near Berkeley, Alameda Co., California, USA, after ca. 50 mm of rain I observed a California scrub jay (*Aphelocoma coerulescens*) attacking a juvenile *Aneides lugubris*. The jay carried the salamander from branch to branch, occasionally holding it down and hammering at it with a woodpecker-like motion. The time involved and the ineffectiveness of the feeding method suggest that *A. lugubris* is not common in the diet of *A. coerulescens*. The salamander's nocturnal habits make interactions with the scrub jay unusual. Mottland (1993. Unpubl. Master's thesis, Stanford University) reported a lack of records for *A. coerulescens* predation on amphibians. Marzluff et al. (1994. Stud. Avian Biol. 15:202–220) indicated that *A. coerulescens* populations are increasing in urban areas, especially during the winter months when *Aneides lugubris* is most active. An aggressive, opportunistic feeder, *A. coerulescens* is able to exploit new food resources, including amphibians.

I thank Jamie Reaser, Steve Rottenborn, and Alan Launer for their assistance.

Submitted by **DANIEL RUBINOFF**, Department of Environmental Science, Policy, and Management, 201 Wellman Hall #3112, University of California, Berkeley, California 94720-3112, USA.

CRYPTOBRANCHUS ALLEGANIENSIS ALLEGANIENSIS (Hellbender). **COLORATION.** Hellbenders are usually described as having a yellowish-brown to black dorsal coloration (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). However, reports of red *Cryptobranchus* are persistent in the herpetological literature. Holbrook (1842. North American Herpetology, 2nd Ed., Vol. 5, p. 99, J. Dobson, Philadelphia) described a red specimen from Buncombe County, North Carolina, USA, as a separate species, *Menopoma fusca*; Grote (1877. Amer. Assoc. Adv. Sci. Proc. 24:255–257) considered them a color variant; Reese (1903. Pop. Sci. Monthly 62:526–531) postulated that females became red "as a secondary sexual character, for the attraction of the males;" and Nickerson and Mays (1972. The Hellbenders: North American "Giant Salamanders." Pub. Biol. Geol. 1:vii+106 pp., Milwaukee Public Museum Press) described a reversible and "rather dramatic color change from an olive-brown background to a rather bright orange," which they considered a response to light and temperature cues. They reported that only one of almost 2000 Ozark hellbenders (*C. a. bishopi*) maintained this unusual background coloration.

On 24 May 1994, one of us (MJK) photographed a live adult *C. a. alleganiensis* with red coloration in Big Walker Creek, Giles Co., Virginia, USA. We observed, but did not photograph, a second large adult with similar red coloration and other reddish hellbenders have been observed at this locality in previous and subsequent years. One retained this coloration under various thermal and light conditions for a week in captivity, at which time it was released.

The color of the individual photographed (Univ. Georgia Mus. Nat. History 24860a,b: Eastman Kodak Color Film 5297 ISO 200), as matched to a Munsell soil color chart (Munsell Soil Color Charts, 1992 rev. ed., Macbeth Division of Kollmorgen Instrument Corp, Newburgh, New York) varied from 2.5YR7/8 (light red) on the innermost portions of the lateral folds to 10R3/3 (dusky red) on the dorsal surface. This coloration is similar to that depicted for *Menopoma fusca* in Holbrook (*op. cit.*, plate 33), which was 2.5YR5/8 (red) on the dorsum and 2.5Y8/8 (yellow) on the venter.

Our observations permit us to discriminate among several of the hypotheses previously offered for this coloration: 1) the observations were made outside the autumnal breeding season (Bishop 1943. Handbook of Salamanders. Comstock Publ. Co., New York) so it is unlikely that the bright coloration functions as a secondary sexual attractant; 2) the animals were outside the range of *Menopoma fusca,* as proposed by Holbrook (1842, *op. cit.).* Recent molecular investigations identify *C. a. alleganiensis* as a single taxon (Meckle et al. 1977. Copeia 1977:1016–1023; Routman 1993. Copeia 1993:407–416), further evidence against the existence of a red species of hellbender; 3) the coloration has been maintained for several days under various thermal and lighting regimes, suggesting that the color change is not a direct response to these conditions. We cannot rule out the possibility that the specimens we observed were simply color variants.

Alternatively, we suggest that the red coloration may be an indication of chronic physiological stress. This hypothesis is consistent with the observations of both Nickerson and Mays (*op. cit.*) and of Grote (*op. cit.*) who mentions that a hellbender that escaped from a tank was found three weeks later and had "changed color very decidedly, becoming a reddish-brown." As additional support for this hypothesis, we have not found sub-adult hellbenders in Big Walker Creek despite several searches, and adults are not active there in the summer months. Cold, rock-strewn streams are considered characteristic hellbender habitat; as a result of nearby deforestation and highway maintenance, however, the large pools in this area of Big Walker Creek are heavily silted. If our hypothesis is correct, the occurrence of reddish individuals in this creek may indicate that the hellbenders are physiologically stressed, possibly due to increased water temperature and decreased oxygen levels associated with sedimentation.

Recently, *C. alleganiensis* has been listed as a species of special concern in Virginia (Virginia Dept. of Game and Inland Fisheries, Richmond) and hellbenders are in decline elsewhere (e.g., in tributaries of the Ohio River; see Pfingsten 1990. Herpetol. Rev. 21:48–51). It would be useful to determine the relationship between chronic stress and coloration in *Cryptobranchus,* and to investigate additional areas to determine if this reddish coloration is prevalent in hellbender populations inhabiting degraded sections of streams.

DESMOGNATHUS QUADRAMACULATUS (Blackbelly Salamander). **REPRODUCTION.** Two modes of egg deposition occur in *Desmognathus* species: laying eggs singly in monolayers (e.g., *D. monticola*; Organ. 1961. Ecol. Monogr. 31:189–220) and laying eggs in grape-like clusters (e.g., *D. fuscus, D. ochrophaeus;* Martof and Rose. 1963. Am. Midl. Nat. 69:376–425). Organ (*op. cit.*) and Pope (1924. Am. Mus. Novit. 153:1–15) reported that *D. quadramaculatus* attach their eggs singly to the undersides of rocks, stones, or other support structures in small clusters that resemble those of *D. monticola*. The eggs appear as a monolayer when attached to flat surfaces and often as bilayers when attached to concave or irregular surfaces. Each egg is suspended individually from a rock or other support structure by a short elastic pedicel that is about 3 mm long and 1.5 mm in diameter.

We observed a single egg mass and an associated *D. quadramaculatus* female at each of two sites in western North Carolina, USA: between Whim Knob and the Heintooga Overlook in the Great Smoky Mountains National Park, Swain Co., and from the Ball Creek watershed of the Nantahala Mountains, Coweeta Hydrological Laboratory, Macon Co. In both cases eggs were laid in large ovoid masses rather than in monolayers. Each mass contained single eggs attached to the rock as well as several clusters consisting of 2–8 eggs that were attached to a common base and twisted about each other to form a common stalk. Trauth (1988. Southwest. Nat. 33:234–236) also observed *D. brimleyorum* egg masses with both single eggs and grape-like clusters of eggs in the same mass. Several *D. monticola* masses that we observed at the Nantahala site were laid in monolayers and all eggs were attached individually to rocks as described by Pope (1924, *op. cit.*). These observations suggest that the mode of egg deposition in *D. quadramaculatus* is more variable than in other *Desmognathus*; females in some populations attach all eggs individually to rocks or other support structures to form a monolayer, while females in other populations appear to attach their eggs both singly and in grape-like clusters within the same clutch.

Submitted by **CHARLES K. SMITH**, Department of Biology, High Point University, High Point, North Carolina 27262, USA, and **JAMES W. PETRANKA** and **REBECCA BARWICK**, Department of Biology, University of North Carolina, Asheville, North Carolina 28804-3299, USA.

DESMOGNATHUS WELTERI (Black Mountain Salamander). **REPRODUCTION.** We are unaware of any published accounts of the eggs or mode of egg deposition for this species. We observed four clutches on the following dates: 8 July 1995 (2), 10 July 1993 (1), and 3 August 1994 (1) along Martin's Fork near Hensley's Settlement in Cumberland Gap National Historic Park, Bell County, Kentucky, USA. All nests were found inside packs of leaves and flood debris on logs or islets in the main stream channel and were 5–20 cm above the level of the stream surface. Each egg was suspended by a transparent pedicel that varied from 4–12 mm long. Pedicels were attached to and twisted about each other so that the eggs of each clutch formed a grape-like cluster similar to that produced by *D. fuscus* and *D. ochrophaeus* (Martof and Rose. 1963. Amer. Midl. Nat. 69:376–425). The diameters of the outer egg capsules of 10 eggs from one clutch averaged 4.5 mm (range = 4.4–4.6 mm). Three of the four clusters were accompanied by females that averaged 66 mm SVL (range = 60–70 mm). Number of eggs per clutch varied from 18 to 33 and averaged 26. Based on the developmental stages of eggs in July 1995 samples, we estimate that eggs were laid no earlier than the first or second week of June.

DICAMPTODON COPEI (Cope's Giant Salamander). **METAMORPHOSIS and PREDATION.** Only three metamorphosed *Dicamptodon copei* have been reported (Nussbaum 1976. Misc. Publ. Mus. Zool. Univ. Michigan 149:1–94; Jones and Corn 1989. Northwest. Nat. 70:37–38). This paper reports three additional confirmed sightings of metamorphosed *D. copei* within Olympic National Park, Washington, USA, and documents evidence of *Thamnophis sirtalis* as a natural predator of metamorphosed *D. copei.*

On 1 August 1994, a large *T. sirtalis* was found basking on a trail in N. Fork Quinault drainage (SE1/4 NW1/4 Sec. 10 T24N R8W). The location was on a steep WSW slope, 1300 m, in an old growth stand. The snake was noticeably swollen and was forced to regurgitate a metamorphosed *D. copei* 11. 5 cm SVL. Its mottled pattern was identical to previous wild-caught metamorphosed adults. The specimen was not collected because of the advanced stage of decomposition. A photograph of the specimen is deposited in the herpetological collection at the University of Washington's Burke Museum (UWBM 2223).

On 30 August 1994 at 1300 h a metamorphosed adult *D. copei* was discovered at N1/2 Sec. 14 T24N R7W, E. Fork Quinault, (L. Welch, pers. comm.). The animal was photographed, but not measured, and its color pattern was the same as the above specimen. We verified the identification by examination of the photo.

On 5 May 1995 a dead, metamorphosed *D. copei* was found by D. Wiedemeier on the banks of an unnamed tributary of Solleks River at 610 m (NE1/4 T25N RlOW; UTM). The specimen measured 157 mm TL, 90.4 mm SVL, and weighed 19.6 g. It was partially decomposed and did not preserve well. The color pattern was similar to the above specimens. The specimen was examined by S. Horton and verified by L. Jones.

PLETHODON CINEREUS (Redback Salamander). **BROODING BEHAVIOR.** Female *Plethodon cinereus* lay and brood their eggs within decaying logs and under logs and stones (Bishop 1943. Handbook of Salamanders. Comstock Publ. Co., Ithaca, New York. 555 pp.), remaining with them through hatching (Bachmann 1964. Maternal Behavior of the Red-backed Salamander, *Plethodon cinereus.* Ph.D. thesis, Univ. Michigan, Ann Arbor). Aggressive defense of eggs and/or nest sites is part of the brooding behavior (Bachmann 1984. Herpetologica 40:436–443; Highton and Savage 1961. Copeia 1961:95–98). This is the first report of relocation of an egg cluster by *P. cinereus.*

On 14 July 1991, I found a female *P. cinereus* attending a clutch of nine eggs within a decaying hemlock (*Tsuga canadensis*) log at the Toft Point Natural Area near Baileys Harbor, Door Co., Wisconsin, USA (T30N R28E Sec. 15). The log crumbled apart when I attempted to roll it over, partly exposing the salamander encircling her egg mass. The salamander remained motionless until I disturbed a small piece of wet wood to which the egg mass was attached. The female then picked up the egg mass in her

mouth, freeing it of the pedicle, and carried it into a crevice deeper in the log. One or two eggs were held in the mouth with the remainder of the clutch projecting in front of the salamander.

Similar behaviors have been observed in at least one other plethondontid. Van Denburgh (1898. Proc. Am. Phil. Soc. 37:139–141) described a captive *Ensatina eschscholtzii* that "moved the eggs from place to place in the jar, holding them always in the crook of its tail," and Kessel (1954. Wasmann J. Biol. 12:133–134) reported a wild *E. eschscholtzii* that carried an egg cluster in its mouth when disturbed.

Field studies were funded by the Cofrin Arboretum and Natural Areas Program of the University of Wisconsin-Green Bay. I appreciate R. G. Jaeger's comments on this manuscript.

Submitted by **DREUX J. WATERMOLEN**, Bureau of Environmental Analysis and Review, Wisconsin Department of Natural Resources, P.O. Box 7921, Madison, Wisconsin 53707-7921, USA. E-mail: waterd@dnr.state.wi.us.

PLETHODON IDAHOENSIS (Coeur d'Alene Salamander). **SNAKE PREDATION.** Other than reports of attempted avian predation (Wilson and Simon 1985. Herpetol. Rev. 16:111), and possible predation by an insect (Staub 1995. Herpetol. Rev. 26:199), no information has been published on predators of *Plethodon idahoensis.* On three occasions (described herein) we have palped this species from red-sided garter snakes *(Thamnophis sirtalis parietalis*). On 24 July 1986 in the Kootenai River Gorge, Lincoln Co., Montana, USA, we retrieved a 2.5 cm *P. idahoensis* tail tip from a fresh road-killed snake (39.5 cm SVL). On 8 June 1987 we palped a neonate *P. idahoensis* (1.8 cm SVL) from an immature *T. s. parietalis* (18.9 cm SVL) above the W shore of Lake Koocanusa, Lincoln Co., Montana, USA. On 16 June 1991 we palped another neonate (2.0 cm SVL) from an immature snake (21.0 cm SVL) found along the North Fork St. Joe River, Shoshone Co., Idaho, USA. Snakes and prey from the Montana sites were deposited in the Charles R. Conner Museum (CM 90-1, 90-2), Washington State University, Pullman. Our observations occurred during field surveys conducted for the USDA Forest Service and the Natural Heritage Programs of Idaho and Montana.

Submitted by **ALBERT G. WILSON, JR.**, Spokane Falls Community College, Department of Mathematics, Science, and Computing, Spokane, Washington 99204, USA, and **EVELYN M. WILSON,** College of Veterinary Medicine, Washington State University, Pullman, Washington 99164, USA.

ANURA

BUFO MARINUS (Giant Toad). **ARBOREAL BEHAVIOR.** On 20 February 1992 just north of Tacuato, Península de Paraguaná, Estado Falcón, Venezuela, we observed two *Bufo marinus* perched in a 5 m high Cuji tree (*Prosopis juliflora*). These individuals were in a natural hole at the base of a large fork ca. 2.5 m above ground; a third specimen was observed on the following night while perched on a limb ca. 1 m above ground.

Arboreal behavior has been reported in species of the *B. typhonius* group (Duellman 1978. Misc. Publ. Nat. Hist. Univ. Kansas 65:1–352; Duellman and Schulte 1992. Copeia 1992:162–172; Hoogmoed 1986. *In* Z. Rocek (ed.), Studies in Herpetology, pp. 147–150. Charles Univ., Prague). This is the first record of arboreal behavior in *B. marinus*.

We thank J. Aranguren, J. Hero, A. Martino, V. Medialdea, and R. Wingfield for their support. This project is partially supported by Fundacite-Falco (S1-9112-030 to AAR and AUM) and Proyecto Bufo, Covenant SCIRO-IVIC (to ML). Our thanks to W. E. Duellman and C. W. Painter who made comments on an earlier manuscript.

BUFO PARACNEMIS (Kururu Guazu, Sapo Buey, Sapo Rococo). **DIET.** *Bufo paracnemis* is a common frog in the Chacoan region of Argentina where it can be found in Jujuy southward to Córdoba and Santa Fe flats; Corrientes, Entre Rios, and Misiones (Cei 1980. Amphibians of Argentina. Monitore Zoologico Italiano (NS) Monog. 2:609). On 9 November 1994, between 2100–2300 h, we collected five specimens (3 males 102.5–119.5 mm SVL; 1 female 170.0 mm SVL; 1 juvenile 79.1 mm SVL) from an open area 15 km N of Corrientes Capital (27°28'S, 58°50'W) Corrientes State, Argentina. An analysis of the stomach contents taken from the males and the single female indicated that the most frequently taken prey items were coleopterans (N = 85; 73% [Scarabaeidae 95.3%; Curculionidae 3.5%; Cerambycidae 1.2%]), hymenopterans (mostly ants, N = 14; 12.1%), hemipterans (N = 7; 6.3%), orthopterans N = 5; 4.3%), and millipedes (N = 5; 4.3%).

The volume (in cm^3) of the items were coleopterans 5.5, hymenopterans 0.18, hemipterans 0.11, orthopterans 0.31, and millipedes 0.17. Coleopterans and hemipterans were present in all stomachs, hymenopterans and orthopterans in three, and millipedes in two. The diet of the four *B. paracnemis* studied was dominated numerically and volumetrically by coleopterans. *Bufo paracnemis* is considered a nocturnal active forager.

Submitted by **MARTA I. DURE** and **ARTURO I. KEHR**, Centro de Ecología Aplicada del Litoral, C.C. 291, (3400) Corrientes, Argentina.

BUFO TERRESTRIS (Southern Toad). **EGG TOXICITY.** Toxicity of toad (*Bufo* spp.) eggs to other anurans has been documented previously (Licht 1968. Herpetologica 24:93–98; Phisalix 1922. Masson et Cie. vol. 2). However, past reports were based on intraperitoneal injection of toad eggs into *Rana pipiens* and *R. temporaria*. On 23 March 1995, while checking pitfall traps surrounding an ephemeral pond on Eglin Air Force Base, Okaloosa County, Florida, USA (T1N, R25W, Sec. 28), I observed fatal toxicity of southern cricket frogs (*Acris gryllus*) by the eggs of southern toads.

Southern toads, entrapped while immigrating to the pond, deposited long strings of eggs in the shallow water within four of the forty-seven 18.9-liter buckets placed every 10 m along the outside of a cloth drift-fence. Large numbers (>30 individuals) of southern cricket frogs were found dead in each of the four buckets containing toad eggs. All cricket frogs found in other buckets containing adult toads, but no eggs, were alive. Death was assumed to be relatively quick based on the fact that healthy cricket frogs, after falling in, usually cling to the sides of the bucket above the water line and are easily capable of climbing out (pers. obs.).

In addition, no live or dying individuals were found in the four contaminated buckets. Cricket frogs are active throughout the day (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part Three: The Amphibians. Windward Publ, Miami, Florida, 191 pp.), and it is likely that some of the frogs were caught just shortly before trap-checking at approximately 0930 h CST.

Besides being repelling to predators by unpalatibility (Licht 1967. Toxicon 5:141–142), egg toxicity may benefit toads by discouraging other anurans from depositing their eggs nearby, thus lessening larval competition for food. In addition, the affected water surrounding the eggs may provide a chemical barrier that repels potential amphibian predators such as newts.

This observation was made in conjunction with a rare-amphibian study supported by the U.S. Department of Defense Legacy Program. I thank Dale R. Jackson for reviewing the manuscript.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

BUFO WOODHOUSII* and *B. AMERICANUS (Woodhouse's Toad and American Toad). **VOCALIZATION.** Advertisement vocalizations of anurans function as premating isolating mechanisms by selectively attracting conspecific mates (Blair 1941. Genetics 26:398–417). The absence of vocalizations in individuals within a chorus would greatly decrease the chances of those individuals obtaining mates, except in instances of satellite behavior. Herein I report the lack of any audible vocalizations in four male toads attempting to vocalize.

On 13 June 1993 two *B. woodhousii* were observed attempting to vocalize at the Auburn University Northern Fisheries Annex ponds in Lee County, Alabama, USA. Each toad was observed for ca. 15 minutes. Both exhibited the typical upright vocalization posture, subsequent lung inflation, and gular sac extension. No audible vocalizations were detected during ca. 10 attempted vocalizations. One partially submerged toad caused vibratory ripples to form along the water's surface while attempting to vocalize. Release vocalizations were not produced when the thoracic region was clasped between the forefinger and thumb. Both toads were marked for future identification. Four days later, one of the two individuals was found at the same locality vocalizing normally.

On 8 March 1994 one *B. americanus* attempting to vocalize was observed in a flooded pasture off St. Rt. 147, 4.8 km N Jct. US Hwy. 280 /147 in Chambers County, Alabama. No audible advertisement vocalization was detected. Release call vocalizations were barely audible although normal release vibrations were exhibited. This individual and a nearby calling male were collected and housed in a 36-liter terrarium. Approximately 22 h later, these individuals were exposed to conspecific advertisement call playbacks in an attempt to elicit vocalizing behavior. Attempts at audible vocalization were unsuccessful in the non-calling male and normal vocalization was elicited in the other. Subsequent exposures to call playbacks in an attempt to elicit vocalization in these individuals were unsuccessful.

On 16 February 1995 a single *B. americanus* was observed at Chambers County Public Fishing Lake, Alabama. This individual also lacked an audible advertisement vocalization and release call. Release vibrations appeared normal. This specimen was sacrificed and dissection of the gonads revealed no detectable abnormalities. The larynx, testes, and Bidder's organs were removed and preserved in Bouin's solution for future morphological analyses.

I thank Mary T. Mendonça and James L. Dobie for their assistance in dissection.

Submitted by **CHRISTOPHER J. LEARY**, Department of Zoology and Wildlife Science, Auburn University, Auburn, Alabama 36849-5414, USA.

EUPSOPHUS EMILIOPUGINI (NCN). **AGGRESSIVE BEHAVIOR.** Aggressive behaviors in anurans include inflation of the lungs, elevation of the body, opening of the mouth, vocalizations, and jumps (Duellman and Trueb 1986. Biology of Amphibians, McGraw Hill, New York. 620 pp.). Because these behaviors are seldom observed, there are only scattered reports. Among the frogs of the family Leptodactylidae, aggressive behavior has been reported among members of the subfamilies Leptodactylinae (*Leptodactylus ocellatus, L. pentadactylus*) (Villa 1969. Rev. Biol. Trop. 15:323–329; Vaz-Ferreira and Gehrau 1975. Physis 34:114); Ceratophrinae (*Lepidobatrachus llanensis, Ceratophrys ornata*) (Barrio 1963. Physis 24:143–148), and Telmatobiinae (*Caudiverbera caudiverbera*) (Veloso 1977. Herpetologica 33:434–442). Here we describe the aggressive behavior of *Eupsophus emiliopugini,* a member of the subfamily Telmatobiinae, which is endemic to the temperate *Nothofagus* forests of southern Chile (Formas 1989. Proc. Biol. Soc. Washington 102:568–576).

Aggressive behavior was observed under laboratory conditions (18°C). Recordings of the vocalizations were made at 19 cm/sec on a Uher 4000 report IC portable tape recorder and a Uher microphone. The audiospectrograms were made with a Kay Elemetric audiospectrograph model using the 85-8000 Hz frequency scale and the narrow (45 Hz) band filter. Oscillograms were made with a model 564 Tektronic oscilloscope. Specimens and tapes were deposited in the amphibian collection of the Instituto de Zoologia, Universidad Austral de Chile.

During the course of a field study of *E. emiliopugini,* we collected 53 adults from four localities in southern Chile (12 specimens from La Picada 41°4'S, 72°26'W, 8 specimens from Rio Lenca 41°37'S, 72°40'W, 15 specimens from Puntra 47°7'S, 73°49'W, and 18 specimens from Yaldad 43°7'S, 73°43'W). All were captured during the breeding season (September to December). The specimens collected at Puntra (12 adult males and 3 adult females) were transported to the laboratory and maintained in a plastic container together with 5 specimens of *E. calcaratus* collected at the same locality. On 22 September we heard some unusual sounds emanating from the box. When the box was opened, one of us (JRF) observed 4 adult males of *E. emiliopugini* with their mouths open and bodies elevated. When each of the animals was tapped on the head, it inflated its lungs, elevated the body further, and emitted a loud cry with the mouth open. This behavior was elicited 3–7 times in each specimen by tapping on the head or dorsum.

The description of the cry of *E. emiliopugini* is based on 17 cries produced by the four males (46.7–50.6 mm SVL) observed in the laboratory at 18°C and recorded immediately after being tapped. The cry consisted of a single note in 12 cases, although secondary notes were detected in 5 cases. The structure of the primary note is modulated and the presumed harmonics are well differentiated. The intervals between presumed harmonics average 317.7 (range 308–319) Hz. The mean duration is 0.98 (range 0.35–1.81) sec. The fundamental frequency ranges between 200 and 340 Hz, and dominant frequency ranges between 3230 and 6250 Hz (Fig. 1). The cry is pulsatile, and the pulses are more concentrated in the middle of the cry (Fig. lc). Each pulse starts

with maximum amplitude and gradually decreases throughout (Fig. 1d).

When the cry of *E. emiliopugini* is compared with its advertisement call (Fig. 1b) some major differences are obvious. The advertisement call is characteristically composed of two notes. Both are similar in duration (mean = 0.20 ± 0.027 sec.) and have 27 pulses (mean) per note. The fundamental frequency ranges from 63–83 Hz and the dominant frequency ranges from 729–1320 Hz (Formas 1989, *op. cit.*). The cry of *E. emiliopugini* is emitted out of water with the mouth open, whereas the advertisement call is produced with the mouth closed while the males are partially submerged.

HYLA FEMORALIS (Pine Woods Treefrog). **PREDATION.** Anuran larvae and adults are preyed upon by many species of vertebrates as well as a host of aquatic invertebrates (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.). Prominent among the invertebrate predators are dytiscid beetles (Allen 1967. Pan-Pacific Ent. 43:113–117; Hinshaw and Sullivan 1990. J. Herpetol. 24:196–197) and odonate larvae (Caldwell et al. 1980. Oecologia 46:285–289; Heyer et al. 1975. Biotropica 7:100–111). Spiders are also known to take anurans (Bastos et al. 1994. Herpetol. Rev. 25:118; Goin 1943. Proc. Florida Acad. Sci. 6:143–154; Groves and Groves 1978. Bull. Maryland Herp. Soc. 14:44–46; Neill 1948. Herpetologica 4:158).

On 27 July 1995, I collected a *Hyla femoralis* tadpole from One Shot Pond, a temporary pond located on the Katharine Ordway Preserve-Carl Swisher Memorial Sanctuary, Putnam Co., Florida, USA. At time of collection a spider was feeding on the tadpole. The spider later was identified as a juvenile *Dolomedes* sp. (Pisauridae), likely *Dolomedes triton*. The spider maintained its grasp on the tadpole for approximately two minutes following dip net capture of both individuals. After the spider released the tadpole, both were placed in 10% buffered formalin. The tadpole apparently had been bitten prior to collection. It did not struggle when dropped into the preservative and digestion of the tissue immediately surrounding the bite already had begun. The location of the spider's bite was visible on the tail musculature of the tadpole just posterior to the body (Fig. 1). The tadpole had a body length of 11.7 mm and a total length of 27.8 mm (Altig 1970. Herpetologica 26:180–207) and was in Gosner stage 40 (Gosner 1960. Herpetologica 16:183–190). The combined cephalothorax-abdomen length of the spider was 10.1 mm.

Fishing spiders of the genus *Dolomedes* are known to prey upon recently transformed frogs as well as adults of species with small body size (Bastos et al., *op. cit.;* Neill, *op. cit.*). *Dolomedes* is also known to prey upon tadpoles (Foelix 1982. Biology of Spiders. Harvard University Press, Cambridge, Massachusetts. 304 pp.). To my knowledge, this is the first account of *Dolomedes* feeding on a *Hyla femoralis* tadpole. Although fishing spiders will eat tadpoles, their significance as tadpole predators, compared to other invertebrates such as dragonfly larvae and predaceous diving beetles, is unknown and in need of further study.

I thank D. A. Johnson for drafting Fig. 1 and G. B. Edwards for identifying the spider.

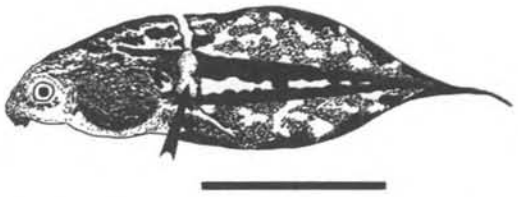

FIG. 1. *Hyla femoralis* tadpole showing spider bite location (arrow). Scale bar = 10 mm.

MIXOPHYES FASCIOLATUS (Great Barred Frog). **TADPOLE PREDATION.** Observations of predation on tadpoles in the wild are rare, yet each observation adds to our limited knowledge of the ecology of amphibian communities. At 1215 h on 19 February 1995, at the Mount William branch of upper Cattle Creek in the rainforest of Eungella National Park, east-central Queensland, Australia (148°36'10"E, 21°01'48"S), we observed the predation of a *Mixophyes fasciolatus* tadpole (ca. 40 mm total length) by an azure kingfisher (*Alcedo azurea*). The kingfisher spent a few minutes perched on a stump about 70 cm above a slow-flowing pool, before it dived into the pool and caught a tadpole. The bird then flew to a nearby perch and swallowed the tadpole head first, showing no indication that the tadpole was distasteful.

We have often observed kingfishers along the streams, and tadpoles of *M. fasciolatus* and other species are common in many of the slow-flowing pools, suggesting that predation events of this type may be frequent. While many studies have concentrated on tadpole predation (Alford, *in press*. *In* R. Altig and R. W. McDiarmid (eds.), Biology of Anuran Larvae. Univ. Chicago Press, Chicago, Illinois), few have considered the effect of birds as predators. Birds are known to readily feed on tadpoles (Beiswenger 1981. Copeia 1981:459–460; Black 1970. Bull. Oklahoma Ornith. Soc. 3:33–34; Crump and Vaira 1991. Herpetologica 47:316–321), and kingfishers, by their aquatic predatory nature and habitual proximity to water bodies, are potentially significant predators of tadpoles. Because this type of predation has been rarely documented for pond tadpoles and perhaps never recorded for stream-dwelling tadpoles (Barker and Vestjens 1989. The Food of Australian Birds. Vol. 1—Non-passerines. CSIRO Division of Wildlife and Ecology, Lyneham, A.C.T.), the extent of this type of predation remains unknown.

Submitted by **E. E. BOLITHO** and **R. W. R. RETALLICK**, Department of Zoology, James Cook University, Townsville, Queensland 4811, Australia.

PHYLLOMEDUSA DISTINCTA (Leaf-frog). **PREDATION.** Phyllomedusine frogs generally display green dorsal coloration that may function as concealment. The vivid colors often present on concealed surfaces and flanks of these frogs may warn potential predators about the presence of skin toxins (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.), or they may produce a startle effect by sudden changes in body shape and color patterns (Endler 1986. *In* Feder and Lauder (eds.), Predator-Prey Relationships, pp. 109–134. Univ. Chicago Press, Chicago and London).

Leaf-frogs and their predators were studied at the Atlantic Forest Reserve of the Parque Estadual de Carlos Botelho (24°12'S, 47°55'W, 60 m elev.), Sete Barras, São Paulo, southeastern Brazil. Observations were made at a pond (ca. 20 m x 7 m) adjacent to a lawn with a few trees and small shrubs. Aquatic vegetation was sparse and concentrated at the pond edges. The surrounding vegetation is tropical rainforest. Climate is wet-mesothermic.

On 13 November 1991 (1100 h; 24.5°C), I observed a water snake, *Liophis miliaris*, ingesting a clutch of *Phyllomedusa distincta* eggs enclosed in a leaf of a shrub (Melastomataceae), ca. 50 cm above the water surface. The snake introduced its head into the upper part of the clutch, thereby forcing open the glued leaf, after which it ingested about half of the eggs. With my approach the snake fled. The snake returned after 70 min and started to ingest another clutch in the same manner. Again, my approach caused the snake to flee.

In the study area, *L. miliaris* is the most commonly observed snake, and accounted for 8 of 15 sightings of snakes around the pond. This snake has variable habits and a generalist diet (Michaud and Dixon 1989. Herpetol. Rev. 20:39–41), hunting in or at the edge of water. It rarely climbs in vegetation. Due to its abundance, *L. miliaris* probably is an important predator of *P. distincta* eggs.

On 11 December 1991 (31°C; 0945 h), I observed the colubrid snake *Chironius exoletus* seizing a male *P. distincta* on a tree branch at the edge of the pond. The snake tried to ingest the prey headfirst, but the frog firmly grasped the branch with its hindlegs. After about 5 min, the snake pulled the leaf-frog from the branch and, with its head raised, began ingestion, which took ca. 25 min. During the next hour, the snake did not show any sign of discomfort [see Sazima (1974. J. Herpetol. 8:376–377) for a report of *Phyllomedusa rohdei* being regurgitated by snakes]. In my study area, individuals of *C. exoletus* are common at the pond edges, where they hunt for frogs in the vegetation. This species accounted for 4 of 15 sightings of snakes around the pond. While I observed one *C. exoletus* investigating bromeliads on a tree, a treefrog jumped from there and fled to the pond and, in spite of the tree's height (ca. 4 m), the snake made its way to the ground searching for the frog, flicking its tongue. *Chironius exoletus* may be an important predator of *P. distincta* adults as these frogs remain in torpor (*sensu* Blaylock et al. 1976. Copeia 1976:283–295) on the vegetation during the day and have no efficient escape movements (pers. obs.).

I am grateful to A. J. Cardoso for guidance during my M. Sc. dissertation. I also thank C. F. B. Haddad, I. Sazima, A. Abe, and P. S. Oliveira for valuable suggestions, the Conselho Nacional de Desenvolvimento Científico e Tecnológico for financial support (proc. 130337/90-0) and the Instituto Florestal de São Paulo for permission to study in the Parque Estadual de Carlos Botelho.

RANA SAKURAII (Brown Stream Frog). **ENDOPARASITES.** *Rana sakuraii is* known only from Honshu Island, Japan where it occurs from Kanto to Kinki Districts (Maeda and Matsui 1990. Frogs and Toads of Japan. Bun-Ichi Sogo Shuppan Co., Ltd. Tokyo, Japan, 207 pp.). In this note we report on an examination of the gastrointestinal tracts from 5 *R. sakuraii* collected on Tanzawa Mountain, ca 700 m elev., (35°22'N, 139°04'E), Kanagawa Prefecture, Honshu Island, Japan, 14 April 1993; N = 5, mean SVL = 47 mm ± 3.6 SD, range 42–51 mm. Frogs were deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM 141210–141214).

The body cavity was opened by a longitudinal incision from throat to vent. The esophagus, stomach, small and large intestine were removed and examined separately using a dissecting microscope. Each parasite was removed and identified using a glycerol wet mount.

The endoparasite fauna of *R. sakuraii* consisted of the cosmocercid nematode, *Cosmocerca japonica* (prevalence: number infected individuals/number individuals examined = 80%; mean intensity: mean number helminths per infected host = 2; infection site: small and large intestines) and the acanthocephalan, *Acanthocephalus lucidus* (prevalence = 60%; mean intensity = 1; infection site: small intestine). All our findings represent new host records. Helminths were deposited in the U.S. National Parasite Collection, Beltsville, Maryland 20705, USA: *Cosmocerca japonica* USNPC 85334; *Acanthocephalus lucidus* USNPC 85335.

We thank Tatsuo Ishihara (Hakone Woodland Museum, Hakone) for the collection of *R. sakuraii*.

TESTUDINES

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider) **REPRODUCTION.** I report the largest known clutch for *Trachemys scripta elegans* and one of the largest known for the Emydinae (*sensu* Ernst and Barbour 1984. Turtles of the World. Smithsonian Inst. Press, Washington, D.C., 313 pp.). The female (250 mm plastral length, 3125 g gravid body mass) was collected crossing the Illinois River Road, near Pohlman Slough in Calhoun Co., Illinois, USA (NE1/4 Sec. 15, T13S, RlW) on 16 June 1995. The largest clutch reported range-wide for this species (excluding tropical races) is 25 eggs (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C., 578 pp.). The clutch reported herein is equivalent to the largest clutch reported for tropical races (Moll and Moll 1990. *In* J. W. Gibbons (ed.), Life History and Ecology of the Slider Turtle, pp. 152–161. Smithsonian Inst. Press, Washington, D.C.). Among other Emydinae, only *Pseudemys nelsoni* (31 eggs/clutch) and *P. rubriventris* (35 eggs/clutch) have been reported to lay larger clutches. Clearly, this is an exceptionally large clutch for *T. s. elegans* which has been reported to lay between 2 and 23 eggs per clutch (Ernst et al. 1994, *op. cit.*)

The 30 eggs averaged 12.09 g mass (range = 8.71–13.51 g, SD = 1.04 g), 35.9 mm long (range = 35.0–40.1 mm, SD = 1.12 mm), and 23.9 mm wide (range = 21.2–25.0 mm, SD = 1.14 mm) shortly after induced oviposition (Ewert and Legler 1978. Herpetologica 34:314–318). After 70 days of incubation at ambient temperatures ranging between 22.1 and 34.6°C, 29 of the eggs hatched. Hatchlings averaged 9.30 g mass (range = 7.92–10.26 g, SD = 0.53 g), 32.4 mm carapacial length (range = 30.9–34.2 mm, SD = 0.78 mm), 31.3 carapacial width (range = 29.0–33.1 mm, SD = 1. 11 mm), and 31.1 mm plastral length (range = 29. 6–32. 6 mm, SD = 0.87 mm) .

LACERTILIA

ANOLIS SCRIPTUS (Silver Key Anole). **ENDOPARASITES.** *Anolis scriptus* occurs on the Bahama Islands and the Turks and Caicos Islands (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies. Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville, 720 pp.). We know of no published reports on the endoparasites of *A. scriptus*. The purpose of this note is to report on an examination of gastrointestinal tracts from 25 *A. scriptus*. Specimens were borrowed from the Museum of Natural History, University of Kansas (KU) (mean snout-vent length (SVL) = 56.8 mm ± 5.4 SD, range = 45-68 mm). Specimens were collected during 1961–1976. Seven (KU 247798–247799; 247808; 247815; 247817; 247822; 247829) were from North Caicos (71°80'W, 21°90'N); thirteen (KU 247832–247834; 247848; 247873; 247924–247925; 247932; 247934; 247939–247942) were from Middle Caicos (71°60'W, 21°50'N); five (KU 247944–247946; 247950–247951) were from East Caicos (71°30'W, 21°40'N).

The body cavity was opened and the gastrointestinal tract was removed by cutting across the anterior esophagus and the rectum. Esophagus, stomach, small intestine, and large intestine were examined using a dissecting microscope. The only parasites present were nematodes which were removed and identified using a glycerol wet mount.

Five species were present: *Abbreviata* sp. (larvae only) (prevalence: number infected individuals/number individuals examined = 4%, mean intensity: mean number nematodes per infected host = 4.0); *Moaciria alvarengai* (prevalence = 16%, mean intensity = 1.0); *Parapharyngodon cubensis* (prevalence = 12%, mean intensity = 1.7); *Physaloptera squamatae* (prevalence = 44%, mean intensity = 4.1); *Spauligodon caymanensis* (prevalence = 4%, mean intensity = 34.0). *Anolis scriptus* is a new host record for the above five nematode species. All nematodes previously have been found in other Caribbean anoles; however, *M. alvarengai* is known previously only in the skink, *Mabuya maculata* from Fernado de Noronha, Brazil (3°51'S, 32°25'W) (Baker 1987. Mem. Univ. Newfoundland Occas. Pap. Biol. 11:1325). Nematodes were deposited in the U.S. National Parasite Collection, (USNPC), Beltsville, Maryland 20705, USA: *Abbreviata* sp. 85445; *Moaciria alvarengai* 85446; *Parapharyngodon cubensis* 85447; *Physaloptera squamatae* 85448; *Spauligodon caymanensis* 85449.

We thank William E. Duellman (Museum of Natural History, University of Kansas) for permission to examine *A. scriptus*.

CNEMIDOPHORUS MURINUS RUTHVENI. (Bonaire Island Whiptail Lizard). **SEEDS IN DIET.** On Bonaire, Netherlands Antilles, 10–44% (depending on site) of the annual diet of *Cnemidophorus murinus* consists of fruit from a variety of plant species (Dearing and Schall 1992. Ecology 73:845–858). The fruit of the shrub, *Erithalis fruticosa* (Rubiaceae), is among the most commonly eaten. As *C. murinus* is exceptionally abundant on the island (Bennett and Gorman 1979. Oecologia 42:339–358), the whiptail lizards could play an important role in the dispersal of the seeds of *E. fruticosa*, provided the seeds can tolerate passage through the gut of the animals.

I compared the germination success of *E. fruticosa* seeds removed from mature fruits still on the shrubs to that of seeds extracted from feces found in the natural habitat of the lizards. In a single morning in January, I visited the Karpata site of Dearing and Schall (ibid). At this site, fully 60% of the diet of *C. murinus* consists of the fruits of *E. fruticosa* during the autumn and winter rainy season. I collected mature fruit from ten shrubs as well as sun-dried feces found lying on the ground surface and tops of rocks used as perches by the lizards. After extracting the seeds of *E. fruticosa* from both fruit and feces, the seeds were planted in a standard germination medium used in horticulture (1:1 vermiculite and perlite). The medium was kept moist and the flats were placed under full-spectrum Vitalites™ kept on 24 h per day in a room set at 28°C. I planted 150 seeds taken from feces in one 27 x 40 cm flat, and another 150 seeds from the fruits in another similar flat.

Seedlings emerged from the medium from 30 to 61 days after planting. No additional seedlings emerged during the next 30 days, after which the medium was discarded. Six seedlings emerged from seeds harvested directly from the fruits, and eight from those removed from feces (4 and 5% germination success). There was no significant difference in germination success for the two groups (G-test, $P > 0.05$).

Although many taxa of animals have been identified as important seed dispersers, few data are available on potential seed dispersal by herbivorous lizards (Iverson 1985. J. Herpetol. 19:292–293). For example, little is known about the tolerance of seeds within the fruit for passage through the digestive tract of a lizard. Iverson (ibid.) found that seeds of *Coccoloba uvifera* (Polygonacae) that passed through the gut of *Cyclura* had slightly higher germination success than control seeds removed from fruits; this suggests that being consumed by a lizard might actually facilitate germination of some seeds. The results presented here show that at least some of the seeds of *E. fruticosa* survive both passage through the gut of *C. murinus* as well as some unknown period of time lying on the surface of the ground and rocks on Bonaire island. Also, the results hint that passage through the lizards' alimentary tract does not facilitate germination because a similar percentage of seeds from the fruit and feces produced seedlings.

The research was funded by a grant from the Whitehall Foundation.

SERPENTES

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). **CARRION FEEDING.** At 1640 h CST on 7 June 1994, Larry Wood and I observed carrion feeding by a cottonmouth, *Agkistrodon piscivorus leucostoma*, at the Chickasaw National Wildlife Refuge, 15 km NW Ripley, Lauderdale Co., Tennessee, USA. We came upon a large individual, ca. 100–110 cm in total length, stretched on the road, feeding on a snake. On closer examination, it was obvious that the cottonmouth was eating a road-killed snake whose body was dried and flattened and showed the marks of having been run over. It appeared to be a colubrid, probably a *Nerodia* sp. We approached the cottonmouth, photographed it, whereupon it moved through the gravel to a flooded ditch beside the road and disappeared into the water. We could not verify how the snake found and began feeding on the roadkill, as it had swallowed a substantial part of the carrion before we arrived.

Gloyd and Conant (1990, Snakes of the *Agkistrodon* Complex: A Monographic Review, pp. 238–239, SSAR) indicate that this subspecies occasionally eats "insects and carrion." Wharton (1966. Copeia 1966:149–161) noted *A. piscivorus* feeding on fish dropped from heron nests, and Berna and Gibbons (1991, Herpetol. Rev. 22:130–131) observed an *A. p. piscivorus* attempt to eat a dead *Nerodia erythrogaster erythrogaster*. This observation is further indication of the opportunistic foraging behavior of this snake (Keiser 1993. Herpetol. Rev. 24:34; Studenroth 1991. Herpetol. Rev. 22:60).

I am indebted to Bill Redmond and Floyd Scott for encouraging me to prepare this note, and to Floyd Scott for assistance. Ray Burkett kindly reviewed the manuscript.

COLUBER VIRIDIFLAVUS (European Whip Snake). **CANNIBALISM.** Reports of snakes feeding on eggs of their own species are exceptional in free-ranging individuals. The European whip snake *Coluber viridiflavus* occasionally feeds on snakes (Duron et Acolat 1957. Ann. Sci. Univ. Besançon 6:179–183), but only one record of cannibalism involving a large male (130 cm total length) feeding on a young conspecific (60 cm total length) has been reported from the field (Naulleau 1984. Rev. Fr. Aquar. 1984:32–35).

We found a large male (144 cm total length, 106 cm SVL, 407 g) killed on the road on 9 July 1995 (C.E.B.C., Forest of Chizé, Road N° D53, 46°07N 0°25W, Département des Deux Sèvres, west central France) with three snake eggs in its stomach and one in its intestine. The eggs were in good condition indicating that they had recently been ingested. They were identified as belonging to *Coluber viridiflavus*, based upon their general appearance, shape, and size. The mean egg length (3.92 ± 0.32 cm, N = 4) was similar to mean egg length (4.30 ± 0.58 cm, N = 53) obtained from clutches of 8 females (ANOVA, $F_{1,52} = 1.68$, $P = 0.183$). In addition, *Coluber viridiflavus* is the only large snake species laying eggs between mid-June and early July in our study area (the second largest oviparous snake, the Aesculapian snake *Elaphe longissima*, lays eggs between late July and early August). The accidentally killed male was found 15 m from a communal nesting site used by female whip snakes (Capula and Luiselli 1995. Herpetol. Rev. 26:38–39). We have regularly found vitellogenic female *C. viridiflavus* sheltered under slabs at the entrance of the nesting site, and also have caught adults males and observed mating at the same place. Apparently males can exploit nesting sites not only for mating but also to feed on eggs of their own species.

Submitted by **LAURENT SCHMIDLIN**, **XAVIER BONNET**, and **CHRISTIAN TEGE**, Centre d'Etudes Biologiques de Chizé, Centre National de la Recherche Scientifique, 79360 Villiers en Bois, Deux Sèvres, France.

CROTALUS DURISSUS (Neotropical Rattlesnake) **PREY.** Although rodents are the predominant prey of *Crotalus durissus*, these pitvipers are also known to feed to a lesser extent on birds and lizards (Salomão et al. 1995. Stud. Neotrop. Fauna Environ. 30(2):101–106; Vanzolini et al. 1980. Répteis da Caatinga, pp. 68 and 110. Acad. Bras. Ciênc.) Here we report the lizard, *Ameiva ameiva* as prey of an adult *C. durissus*. The snake is a female (Instituto Butantan (IB) 15935; 743 mm SVL) from São Paulo, Brazil (21°12'S and 50°25'W) captured on 19 January 1954 (summer). Its stomach contents showed the presence of ventral and dorsal scales, as well as the feet of *A. ameiva*, ingested head first. The total length of the lizard (400 mm) was estimated from the size of bones and scales.

We thank H. Ferrarezzi and M. T. U. Rodrigues for the identification of the lizard and discussions, O. A. V. Marques for the suggestion to prepare the manuscript, M. G. Salomão for comments and translation into English, and F. C. Costa for final revision.

Submitted by **SELMA MARIA ALMEIDA SANTOS** (to whom correspondence should be addressed) and **VALDIR JOSÉ GERMANO**, Laboratório de Herpetologia, Instituto Butantan, Av. Dr. Vital Brazil, 1500, Butantã, São Paulo - 05503-900, Brazil.

CROTALUS EXSUL LORENZOENSIS (San Lorenzo Island Rattlesnake). **ARBOREAL BEHAVIOR.** On 7 July 1995 at ca. 2200 h, in an arroyo on the southwest side of Isla San Lorenzo Sur, Baja California, México, an adult *Crotalus exsul lorenzoensis*

was observed active on the ground near the margins of an elephant tree (*Bursera microphylla*). When approached, the snake climbed into the lower branches of the tree and ascended to a height of 2.0 m above the substrate, eventually coming to a rest and coiling in the upper branches. This behavior suggests that this population is partially arboreal in its habits. Similar arboreal tendencies have been observed in the insular rattlesnakes *C. enyo cerralvensis* (McGuire 1991. Herpetol. Rev. 22:100) and *C. catalinensis* (L. Grismer, pers. comm.). A total of three *C. exsul lorenzoensis* were observed within the arroyo, two of which had degenerate rattles. It is of interest that *C. catalinensis* also lacks a rattle. These species' arboreal tendencies and the loss of a rattle may be linked to the predation of birds or other arboreal animals (Grismer, pers. comm.).

CROTALUS HORRIDUS (Timber Rattlesnake). **REPRODUCTIVE PHENOLOGY.** Estimates of parturition dates for *Crotalus horridus* in nature, based on the finding of postpartum females with premolt neonates, range from early August to early October. Between 1969 and 1990, I found postpartum females with litters from 9 August to 16 October with latest known parturition on 3 October. The years of 1991 and 1992 represented extremes in active season temperatures and provided records both earlier and later than previously observed (Martin 1992. *In* J. A. Campbell and E. D. Brodie, Jr. (eds.), Biology of the Pitvipers, pp. 259–277. Selva, Tyler, Texas).

Female *C. horridus* usually stay with their young 7–10 days and neonates usually molt within 8–16 days of birth (Martin 1992, *op. cit.*); thus, the timing of parturition can be estimated within a week to 10 days when a postpartum female is present with a litter of premolt neonates. Most of the observations in this note were made in the northern portion of the Blue Ridge physiographic region from the Catoctin and South Mountain complex in Maryland southward to Shenandoah National Park in Virginia (USA). Additional observations were made at two sites located on the Allegheny Plateau in central Pennsylvania and northern West Virginia (USA).

Parturition dates in 1992, a year with an unusually cool, wet growing season, were 4–6 weeks later than those in 1991 when the growing season was much longer, hotter, and drier than usual. The earliest parturition occurred between 31 July and 3 August 1991 as a female was found pregnant on 30 July and postpartum with young on 4 August. The latest birthing probably occurred shortly after 10 October 1992 as a pregnant female was found on that date accompanied by a postpartum female with a litter apparently born within a day.

In 1992 at a high elevation Allegheny Plateau site located in Grant Co., West Viriginia, pregnant females entered hibernation carrying unborn young (Table 1) just as they had done in 1989. Neither those females nor young from the 1989 and 1992 cohorts

TABLE 1. Significant observations of *Crotalus horridus* litters with postpartum females and near-term pregnant females are shown for the years 1991, 1992, and 1994 (reproduction was low in 1993 and no significant observations were made). The date of observation is followed by the number of litters and the number of pregnant females. An asterisk indicates the pregnant females returned to the overwintering den for parturition and two asterisks indicate the pregnant females entered hibernation without birthing. Temperature departures from the mean for Shenandoah National Park Headquarters at Luray, Virginia for the April–September period were +1.7°C in 1991, –1.1°C in 1992, and 0.0°C in 1994.

have been found. Significantly, in 1994, a year in which active season temperatures were near normal, at least one pregnant female seen at a birthing rookery in mid-September at the Grant Co. site, as well as a female from a high elevation Blue Ridge site, returned to overwintering dens for parturition at the time when ingress was in progress in late September (Table 1).

CROTALUS HORRIDUS (Timber Rattlesnake). **CLIMBING.** While tracking timber rattlesnakes (N = 12) during a telemetry study in Nacogdoches County, Texas, USA, we captured an immature female *C. horridus* (75.4 cm SVL, 173.5 g WT) on 1 April 1993 and implanted a transmitter subcutaneously. On 10 August 1993 we located the snake 3.5 m above ground on small limbs (1 cm diam) of an 11 cm DBH American hornbeam (*Carpinus caroliniana*). On 18 August 1993 the snake was found 52 m from the previous location on the ground. Nine months later, 5 May 1994, we found the same snake 7 m up in a tangle of greenbriar (*Smilax* sp.) and small limbs of a 40 cm DBH willow oak (*Quercus phellos*). The next time we found the snake, 10 May 1994, it was found in small tertiary limbs 9 m above ground in the same tree, which is much higher than ever reported for this snake species.

The size of the rattlesnake was probably an important factor in its ability to climb. Rudolph (1990. Wilson Bull. 102(1):14–22) found that smaller *Elaphe obsoleta* were more adept climbers than larger ones, so it is not surprising that the only rattlesnake we observed climbing was the smallest in the study (snakes ranged in size from 75.4 cm SVL, 173.5 g to 137.2 cm SVL, 2654 g). We did not find evidence of a bird nest or flood waters in the immediate vicinity of the climbing snake which might cause this unusual behavior.

We thank Fred L. Rainwater, Paul D. Klawinski, and Bob R. Fleet for constructive comments on an early draft of this note.

CROTALUS LEPIDUS (Rock Rattlesnake). **AQUATIC BEHAVIOR.** On 5 August 1995 at ca. 1700 h, MST, I observed aquatic behavior in *Crotalus lepidus* at the South Fork Negrito Creek (NW 1/4 of SW 1/4 Sec. 32, T8S, R17W, elevation ca. 2141 m), Catron County, New Mexico, USA. Here, the creek flows through a rocky, sheer-sided canyon 73 m deep, where several *C. lepidus* were observed. I observed a *C. lepidus* (40 cm TL) submerged in a 1 m deep, 2 m x 3 m pool; air temperature was approximately 35°C while the water was approximately 16°C. The snake was lying on a rock ledge under 0.5 m water adjacent to the central, deepest portion of the pool. The snake was completely submerged with its head and anterior portion of body elevated and suspended over the deeper water. Numerous small fishes also were in the pool swimming in the deep water. It appeared the rattlesnake could have been foraging for these fish. After observing the snake for several minutes I disturbed it while attempting to catch it. The snake swam to the surface and then across to the edge of the pool. I subsequently was unable to find it.

Crotalus lepidus swims well, although aquatic behavior in rattlesnakes is rare (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed. Univ. California Press, Berkeley. 1533 pp.). The aquatic behavior I observed may be attributable to either thermoregulation or foraging. *Crotalus lepidus* is mostly diurnal but seeks cool shelter during the hottest part of the day (Ernst 1992. Venomous Reptiles of North America. Smithsonian Inst. Press., Washington. 236 pp.). Cool water could offer such a shelter. Unlike most rattlesnakes, *C. lepidus* tends to rely on vision for foraging and feeds mostly on exothermic prey, particularly lizards (Ernst 1992, *op. cit.*). Conceivably, fish may provide a locally common food source for a visual predator such as *C. lepidus*, although predation on fish has never been documented for this species.

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake). **RESPONSE TO FIRE.** Immediate and long-term effects of fire on snakes are not well known, although many snakes evolved in fire-maintained habitats, and prescribed burning is widely used by wildlife managers. It is generally thought that reptiles burrow to escape fire, but few direct observations have been published. We describe behavior of two radio-telemetered *Elaphe o. obsoleta* in response to a prescribed burn in the Ouachita National Forest, Arkansas, USA.

On 28 March 1993, U.S. Forest Service staff burned 312 ha of mature shortleaf pine (*Pinus echinata*) forest and clearcut regeneration. Two adult female *E. o. obsoleta* (SVL 120 cm and 108 cm) were monitored during the burn. Each snake contained a surgically-implanted temperature-sensitive transmitter.

Snake 1:—Snake 1 was located moving through the regeneration area at 1020 h, with a body temperature of 26.2°C. By 1145 h the snake had traveled 16 m ahead of the advancing fire, into a forested ephemeral drainage. At 1217 h it entered a cavern beneath an unvegetated 6-m slab of rock under trickling water. We began minute-by-minute telemetric monitoring of the snake's body temperature at 1325 h, along with air temperature 1 cm above ground ("surface temperature") near the rock slab. From 1325 h to 1402 h surface temperature rose from 23.8°C to 32.0°C as flames approached within 2 m of the snake's position. By 1520 h surface temperature fell to 19.3°C. From 1325 h to 1520 h the snake's body temperature remained between 15.7°C and 16.9°C, rising to 18.0°C only twice. Body temperature thus remained cool and constant despite the rise in surface temperature.

Snake 1 was subsequently tracked for 14 months and behaved normally. Radiotracking data showed no evidence of attraction or aversion to the burned area. Snake 1 was located within the burned area 17 of 26 times (65.4%) in 1993 after the fire, while in 1992 (before the fire) it was found in this area 23 of 31 times (74.2%) ($X^2 = 0.19$, df = 1, $P = 0.66$).

Snake 2:—Snake 2 was located at 1115 h in pine forest 500 m from Snake 1. Topography was level, with no drainages within 100 m. Body temperature was 26.0°C; surface temperature was 25.4°C. The snake was entering a log it had occupied as a retreat site on multiple previous occasions. One hour after the fire, the log was found destroyed, but the snake was located underground 13.5 m away, in root caverns of a charred stump. Its body temperature stayed between 10.7°C and 13.3°C from 1628 h to 1657 h. Surface temperature at 1628 h was 26.4°C. While the snake's

behavior was not observed directly, it apparently moved from a favored retreat site and took refuge in cool insulated caverns.

The snake was still in these caverns on 8 April, had moved to a new site by 11 April, and was found high in a tree cavity on 17 April. On 25 April it was found dead on a road 150 m from the tree, crushed by a vehicle. The snake's movement prior to its death, however, suggested it suffered no harm from the fire.

Snakes are often assumed to survive fire by moving underground, but few published observations confirm this. Jackson (1976. Herpetologica 32:359–361) showed *E. o. spiloides* to be more arboreal than *E. o. obsoleta*, and suggested that in southeastern pine forests lacking rocky caverns they may climb trees to escape fire. Our observations show that in a region featuring both fire-dependent pine forest and rocky soil, *E. o. obsoleta* can find refuge from fire underground.

Fire often benefits vertebrates by improving foraging habitat or increasing prey populations. Mushinsky (1985. Herpetologica 41:333–342) showed that snake populations can benefit from fire. Direct and long-term effects of fire on snakes presumably vary with foraging requirements, shelter-seeking behavior, predation pressure, and nature of the fire (Friend 1993. Biol. Conserv. 65:99–114). Our finding that Snake 1 showed no long-term attraction or aversion to burned areas supports the idea that multiple factors may influence their suitability.

We thank G. Bukenhofer, R. Masters, W. Montague, and K. Smith for critiques of the manuscript. Funding was provided by Ouachita National Forest, Southern Forest Experiment Station, Poteau Ranger District (Ouachita N.F.), and Arkansas Audubon Society Trust. We thank W. Montague and Poteau Ranger District fire crews for their kind cooperation.

HETERODON PLATIRHINOS (Eastern Hognose Snake). **MORTALITY.** On 2 November 1994 I captured an adult female *Heterodon platirhinos* (66.5 cm TL, 270 g) near Searcy, White County, Arkansas, USA. She contained six firm masses approximately the size and shape of oviductal eggs (ca. 18 x 31 mm) in the posterior part of her body. After capture, I released her into a 7 x 15 m outdoor enclosure containing diverse microhabitats including hibernacula, several other *H. platirhinos*, and toads, *Bufo woodhousii*, for food. The other *Heterodon* were long-term residents of the enclosure where they successfully foraged, reproduced, grew, matured, and overwintered. After emergence from hibernation in early April 1995, the snake with the masses appeared healthy despite the now firmer composition of the masses. However, through spring and early summer 1995, she gradually lost weight, became emaciated, and eventually died on 2 July. Autopsy revealed five firm oviductal eggs (total weight = 35 g) and a hardened intestinal fecal mass (weight = 20 g) anterior to the eggs. The weight of the dead snake was 133 g. Assuming no change in mass of the eggs or fecal mass, she had lost 82 g or 38% of her body weight since capture. The eggs exhibited no gross signs of embryonic development.

Egg retention is the norm in oviparous squamates (Shine 1985. *In* Gans and Billett (eds.), Biology of the Reptilia, Vol. 15, pp. 605–694. Wiley-Interscience, New York); nevertheless, deaths of female snakes associated with abnormal retention of eggs or embryos have been reported (e.g., Fitch 1970. Univ. Kansas Mus. Nat. Hist., Misc. Publ. 52:1–247; Plummer 1992. Copeia 1992:1096–1098). Because the time of capture of the snake (2 November) was at least two months after the latest known time of oviposition for this species (Platt 1969. Univ. Kansas Publ., Mus. Nat. Hist. 18:253–420), the retention of eggs was likely abnormal at the time of capture. She probably did oviposit successfully before capture as the average clutch size for a *H. platirhinos* of her size is 22 eggs (Platt, *op. cit.*). Because the anteriormost hardened fecal mass did not increase in size over a period of eight months after capture and because her body weight gradually decreased until death, probably she did not feed after the time of capture, despite the availability of toads. Was the cessation of feeding related to egg retention? Egg retention may have physically prevented feeding via intestinal blockage as evidenced by the hardened fecal mass—immediately anterior to the eggs—which did not move either posteriorly in the body or relative to the eggs from 2 November 1994 to 2 July 1995. Egg retention also could have suppressed the feeding response as commonly occurs in gravid snakes (Murphy and Campbell 1987. *In* Seigel et al. (eds.), Snakes: Ecology and Evolutionary Biology, Macmillan Publ. Co, New York). Because this evidence is anecdotal and circumstantial, it should be interpreted with caution. Nevertheless, these observations suggest the possibility that abnormal prolonged egg retention in snakes may directly or indirectly interfere with feeding and may become a source of mortality.

Submitted by **MICHAEL V. PLUMMER**, Department of Biology, Box 2251, Harding University, Searcy, Arkansas 72143, USA.

NINIA SEBAE SEBAE (Red Coffee Snake). **REPRODUCTION.** On 1 January 1995, two snake eggs were found 3 km SSW of the Belize Zoo about 0.2 km W of the road intersection at La Democracia (near 17°20'20"N, 88°33'45"W), Belize District, Belize. The eggs were in a small earthen cavity under a log. The white leathery shell of each egg was very clean and no development could be discerned by candeling, indicating they were recently laid. The eggs measured 16 x 9 mm and 18 x 8 mm. After collection they were maintained on moist paper towels at an average temperature of near 25°C until hatching. During incubation the eggs increased in size, measuring 24 x 11 mm and 26 x 10 mm prior to hatching. On 6 March 1995, one egg was opened and a dead *Ninia sebae* removed (UTEP 15964). The snake measured 119 mm in total length. The second egg hatched on 10 March. The snake measured 123 mm in total length and weighed 1.0 g. (UTEP 15991). Incubation periods were at a minimum 65 and 69 days. The eggs were collected in Belize under authority of permit CD/6013/94(41).

REGINA RIGIDA (Glossy Crayfish Snake). **BEHAVIOR.** On 2 March 1995, a pair of *Regina rigida* were found submerged amongst heavy aquatic vegetation in a shallow portion of a borrow pit. This species is commonly found throughout much of southeastern Georgia in similar habitat, hidden in such vegetation, leaf litter, or mud during the daylight hours (pers. obs.). However, on this occasion these specimens were found actively swimming at 1155 h on a bright sunny day. Upon closer examination, it was found that the smaller individual (male, SVL = 28.7 cm; TL = 37.8 cm) was clearly biting the larger specimen (female, SVL = 35.1 cm; TL = 45.2 cm) about midway down the

body. This behavior was assumed to be associated with courtship, although copulation was not observed. No mention of biting was made by Ford (1982, Herpetol. Rev. 13:72) in discussing the courtship of a related species, *R. septemvittata*. However, biting during courtship in other species of snakes is known to occur (Gillingham 1979. Copeia 1979:319–331; Tinkle 1951. Copeia 1951:77–78).

SORDELLINA PUNCTATA (NCN). **DIET**. The single species of the genus *Sordellina* is reported mainly from the Atlantic Forest in southern Brazil (Hoge and Romano 1976/77. Mem. Inst. Butantan 40/41:63–70). *Sordellina punctata* averages 400–600 mm in total length and seems to be aquatic and diurnal (pers. obs.). This snake displays morphological features related to aquatic habits, including dorsal placement of eyes and nostrils. Although published information states that "this snake lives in fields not far from water and woods, hunting for frogs on which to feed" (Amaral 1978. Serpentes do Brasil, Melhoramentos/Univ. São Paulo, 246 pp.), no substantiated data on food of *S. punctata* are available. Here I report on gut contents of one snake found in the wild and four specimens housed in the collection of the Instituto Butantan (IB) in São Paulo.

One adult female *S. punctata* (SVL = 500 mm, tail = 130 mm) was found in the morning of 4 October 1995, resting on the ground within restinga scrub at the Estação Ecológica Juréia-Itatins, São Paulo (24°25'S, 47°14'W). Upon capture it disgorged remains of a giant earthworm (Glossoscolecidae). An adult male (IB 40285, SVL = 430 mm, tail = 105 mm), contained one semi-digested earthworm. Estimated prey/predator mass ratio for the two above snakes was 0.3 and 0.05 respectively. Feeding both on small and large prey is common for most snakes (Arnold 1993. *In* Seigel and Collins (eds.), Snakes: Ecology and Behavior, pp. 87–115. McGraw Hill, New York). Additionally, two snakes (IB 22936 and IB 41071) had earthworm setae (probable from Glossoscolecidae) in their hindgut. Glossoscolecid earthworms are surface active during and after rainfall (pers. obs.), some species being partly aquatic (G. Righi, pers. comm.). Two captive *S. punctata* ate small fish and tadpoles (I. Sazima, pers. comm.; pers. obs.).

I thank I. Sazima for reading the manuscript and G. Righi for information, and identification of the earthworm prey.

THAMNOPHIS RUFIPUNCTATUS. (Narrow-headed Garter Snake). **MAXIMUM SIZE**. On 11 September 1995, in the San Francisco River near Pleasanton, Carton County, New Mexico, USA, we captured an obviously emaciated adult female *T. rufipunctatus* with the following measurements: 880 mm SVL, 235 mm TL, 1115 total length, and 176 g. This exceeds the maximum total length of 953 mm reported by Boundy (1994. Herpetol. Rev. 25:126–127). The specimen is MSB 59509 in the herpetology collection at the University of New Mexico.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 27, Number 2 (June 1996).

CAUDATA

AMBYSTOMA CALIFORNIENSE (California Tiger Salamander). USA: CALIFORNIA: San Mateo Co: 368 Albion Avenue, Woodside, 400 feet (122 m) elev. 14 October 1962. Galen B. Rathbun. Verified by Jens V. Vindum. CAS 197631 (freeze dried juvenile specimen). New county record that extends the historic range of this salamander north along the San Francisco peninsula, some 8.5 km northwest from th well-known population at Stanford University, Santa Clara County (Barry and Shaffer 1994. J. Herpetol. 28:159–164). The salamander was originally collected for a high school science project and a detailed locality tag was still attached to the specimen when it was recovered some 32 years later in the home of Dr. Rathbun's parents. The specimen was originally taken from the vicinity of an old sag pond, but the source population is apparently now extinct due to the loss of breeding ponds from subsequent housing developments in the region (pers. observ.).

MMTT 2122–2128, ZMGU 75; Yeilogh-e-Sarasi. 1 August 1991. M. Khoshchin. MMTT 2121. GILIAN PROVINCE: Fuman area, shaft, ca. 21 km SW Rasht, 37°14'N, 49°18'E, 12 m below sea level (15 m above Caspian Sea). Autumn 1991. K. Nostati. MMTT 2129. MAZANDARAN PROVINCE: 70 km E Gorgan, Shirabad Cave, ca. 36°58'N, 55°2'E, 400 m elev. 8 July 1993. Baluch, H. G. Kami, Parsa. Field No. 1–12, Baluch collection in Tehran University (5 juveniles, 7 larvae collected). Easternmost record for species. MAZANDARAN PROVINCE: Shirabad Cave. Rahmani, Naghghash, Darianabard. Juvenile and adult specimens; two alive in Zoological Collection, Gorgon University (cat. no. pending).

Submitted by **HAJI GHOLI KAMI** and **EBRAHIM VAKILPOURE**, Department of Biology, Faculty of Sciences, Agricultural Sciences and Natural Resources of Gorgan University, Iran.

GYRINOPHILUS PALLEUCUS (Tennessee Cave Salamander). USA: GEORGIA: Walker Co: ca. 2 km W Kensington in Chattanooga Valley. 16 September 1995. K. A. Buhlmann, J. P. Demuth, C. A. Hobson, K. Huffines, A. Padgett, K. Padgett, and M. A. Pilgrim. Verified by Jeremy F. Jacobs. Four larval salamanders were observed and one was collected (USNM 497687) in a shallow, gravel-bottomed, permanent stream within a large cave (name withheld due to sensitive nature of the cave). *Gyrinophilus palleucus* was first reported from Georgia by Cooper (1968, J. Alabama Acad. Sci. 39:182–185) based on a specimen from Harrisburg Cave, Pigeon Mountain, Walker County, Georgia. No additional specimens have been reported from Georgia, and recent

publications (Frost 1985, Amphibian Species of the World: A Taxonomic and Geographic Reference. Allen Press, Lawrence, Kansas. 732 pp.; Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.; Williamson and Moulis 1994, Distribution of Amphibians and Reptiles in Georgia. Savannah Sci. Mus. Special Publ. No. 3, Savannah, Georgia, Vol. 2, 712 pp.) have not included Georgia in the range of *G. palleucus*. This specimen confirms the presence of *G. palleucus* in Georgia, extending the range in the state ca. 19.5 km northward from Harrisburg Cave, on the eastern side of Pigeon Mountain, to the new locality near the eastern slope of Lookout Mountain, and thus supports extending the range of *G. palleucus* eastward from northeastern Alabama into the Pigeon/Lookout Mountain area of northwestern Georgia. Other populations of *G. palleucus* should be expected in this area.

SIREN INTERMEDIA NETTINGI (Western Lesser Siren). USA: LOUISIANA: TERREBONE PARISH: Houma, 1.3 mi (2.09 km) SW jct. La Rt. 24 on Savanne Road, or 1.1 mi (1.77 km) NE jct. La Rt. 311 on Savanne Road. 1 January 1996. Bryan Butcher and Tia Butcher. Ernest A. Liner Collection (EAL 5240, 19 specimens); same location as above. 2 January 1996. Ernest A. Liner, Bryan Butcher and Tia Butcher. EAL 5242 (15 specimens). All verified by Harold A. Dundee. First records for the parish; extend the range from St Charles (25 mi, 40.23 km), Ascension (25 mi, 40.23 km), and Assumption (25 mi, 40.23 km) parishes to the east and north and St. Mary Parish (35 mi, 56.32 km) to the west of the previous locations as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **BRYAN BUTCHER, TIA BUTCHER,** 104 Mike Street, Houma, Louisiana 70360, USA, and **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA.

ANURA

BUFO ARENARUM (Common Toad) ARGENTINA: CHACO: Resistencia City (27°27'S, 58°58'W). 6 October 1995. Jorge A. Céspedez. Verified by Blanca Beatriz Alvarez. Colección Herpetológica de la Facultad de Ciencias Exactas y Naturales y Agrimensura. (UNNEC 04355 y 04356). First province record; extends the range of this species 100 km from the latter record in the north of Santa Fé province [Gallardo and Varela de Olmedo 1992, Fauna de Agua Dulce de la Republica Argentina. (41):1–116] and represents the northernmost record for the species in the central portion of its range.

Submitted by **JORGE ABEL CÉSPEDEZ**, Compared Anatomy, Biology Department, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de julio 1449, 3400, Corrientes, Argentina.

BUFO BOREAS (Western Toad). USA: ALASKA: Montague Island, Patton Bay, (59°57'N, 147°30'W). Fully metamorphosed toad, 24 mm SVL, captured, photographed, released 9 September 1991. Verified by Bruce Wing. Since 1988 numerous ADF&G personnel have observed toads on Montague Island with its maritime climate and coastal vegetation. Tasnuna River, (61°02'N, 145°07'W). Large adult, 65 mm SVL, captured, photographed, released 25 August 1992. Verified by Bruce Wing. The Tasnuna River capture site is separated from Prince William Sound by a nearly continuous glacial expanse along the crest of the Chugach Mountains. Only two obvious migratory corridors from the coast exist: up swift, turbid Copper River, or up Lowe River from Valdez, over Marshall Pass, and down upper Tasnuna River. Currently three glaciers (Childs, Miles, and Allen) terminate on Copper River. Another (Heney) has recently retreated a short distance from the river. If ancestral toads migrated up Copper River after the last period of extensive glaciation they presumably would have crossed some combination of these glaciers. A route up Lowe River from Valdez represents a shorter migration, but requires crossing treeless 550 m Marshall Pass. Regardless of migratory pathways, the climate of Tasnuna River drainage today is significantly harsher than the coastal climate of Prince William Sound. The Tasnuna River specimen represents the westernmost mainland record and northernmost record to date (Hodge 1976, Amphibians and Reptiles in Alaska, the Yukon and Northwest Territories. Alaska Northwest Publ. Co., Anchorage. xi + 89 pp). Voucher photographes, locality maps and field notes of the senior author have been deposited in the herpetological collections (AB 91-16, Patton Bay, Montague Island, AB 92-21, Tasnuna River) of NOAA, NMFS, Alaska Fisheries Science Center, Auke Bay Laboratory, 11305 Glacier Highway, Juneau, Alaska 99801, USA, under the curatorship of Bruce Wing. The herpetological collection of the junior author, formerly held at Tongass Historical Society Museum in Ketchikan, Alaska, was transferred to Auke Bay Laboratory in 1993.

Submitted by **MICHAEL WIEDMER,** Alaska Department of Fish and Game, 333 Raspberry Road, Anchorage, Alaska 99518, USA and **ROBERT PARKER HODGE**, 181 Raft Island, Gig Harbor, Washington 98335, USA.

BUFO BUFO (Common European Toad). IRAN: MAZANDARAN PROVINCE: Ghorogh Jungle, 25 km E Gorgan, ca 36°54'N, 54°44'E, 140 m elev. 25 April 1995. Dariush Samadi. ZMGU 74. Easternmost record for species; extends distribution 150 air km NE Sari (Eislet and Schmidtler 1973, Ann Naturhistor Mus. Wien 77:215–20; Tuck 1974, Herpetol. Rev. 5:107).

Submitted by **HAJI GHOLI KAMI** and **EBRAHIM VAKILPOURE**, Department of Biology, Faculty of Sciences, Agricultural Sciences and Natural Resources of Gorgan University, Iran.

BUFO WOODHOUSII WOODHOUSII (Woodhouse's Toad). USA: TEXAS: FLOYD CO: Caprock Canyons Trailways State Park, UTM coordinates 14 304523E 3790798N. 5 June 1996. F. D. Yancey, II and K. J. Roberts. Verified by Clyde Jones. The Museum of Texas Tech University (TTU 11556). New county record; fills gap between Hale and Motley counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II** and **KRISTIE JO ROBERTS**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

CENTROLENE BUCKLEYI (Ranita Verde de Labio Blanco). VENEZUELA: ESTADO MÉRIDA: Municipio Miranda: stream in road Piñango to Timotes (vía Latafayez), 2625 m elev. 11 June 1988. HYLA ARBOREA (European Treefrog). GREECE: NORTHERN SPORADES: Island of Skopelos, outskirts of Panormos (on the west coast of the island). 21 June 1995. Johnny Johnsen. Verified by Wolfgang Böhme. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn (ZFMK 61476). First record for Skopelos and for the archipelago of the Sporades [Werner 1938, Zoologica 35(94):1–117; Grillitsch and Tiedemann 1984, Ann. Naturhist. Mus. Wien 86B:7–28]. On the Aegean islands, *H. arborea* seems to be rather sparsely distributed, with the nearest published island occurrences on Thasos, Lesbos, Chios, Evvia, Tinos, Naxos and Milos [Werner 1938, *op. cit.*; Daan 1967, British J. Herpetol. 3(12):312–313; Broggi 1978, Salamandra 14(4):161–171; Hingley and Castle 1991, Herptile 16(2):75–80]. But the record from Milos is based on a voice record, and Beutler and Frör (1980, Mitt. zool. Ges. Braunau 3(10/12):255–290) question the very old records from Tinos and Naxos. On other Aegean islands, *H. arborea* occurs on Crete (widespread and abundant), Kos and Rhodes (common) [Calabresi 1923, Boll. Mus. Zool. Anat. Comp. 38:1–16; Zavattari 1929, Arch. Zool. Ital. 12/13:161–166; Wettstein 1931, Ann. Naturhist. Mus. Wien 45:159–172; Tortonese 1948, Arch. Zool. Ital. 33:379–402; Wettstein 1953, Sber. österr, Akad. Wiss., Math.-Naturw. Kl., Abt. 1, Wien 162(9/10):651–833; Wettstein 1967, British J. Herpetol. 3(12): 313–314; Strijbosch 1984, Lacerta 42(4):62–71; Sowig 1985, Salamandra 21(4):252–262; Stugren and Lydaták 1986, Zool. Abh. Mus. Tierk. Dresden 42(4):57–64]. *Hyla arborea* is widely distributed in mainland Greece. Stugren and Lydaták (1986, *op. cit.*) have redefined *H. a. kretensis* from Crete to be characterized by possessing a red spot on the upward branch of the lateral stripe and red coloration on the back of the front limbs. The specimen from Skopelos does not have this red coloration and seems to belong to the nominate subspecies.

Submitted by **HENRIK BRINGSØE**, Esthersvej 7, DK-4600 Køge, Denmark.

PELOBATES SYRIACUS (Syrian Spadefoot) GREECE: PELOPONNISUS: Achaia Prefecture: marshes and wet meadows between the village of Metochi and the lake of Lamia in the area of the Strofilia Wood, 38°04'N, 21°22''E, ca. 0 m elev. 12 September 1995. G. Chiras and B. P. Chondropoulos. Verified by A. Dimitropoulos. Zoological Museum of University of Patra (ZMUP A-R 1366–1367, recently metamorphosed; 1368, adult female). Range in Greece seems to be discontinuous within the northern and central parts of the mainland. To the south, in the Peloponnisos region, *P. syriacus* was previously known from only two records (Bohme 1975, Senck. biol. 56:199–202; Bringsøe 1994, Ann. Musei Goulandris 9:349–374), which lie in mountainous areas 107 and 42 km (direct line distances) SE and ENE of our recorded locality, respectively. The present record is the first for lowland and coastal Peloponnisos.

Submitted by **BASIL P. CHONDROPOULOS**, Section of Animal Biology, Department of Biology, University of Patra, 260 01 Patra, Greece, and **GEORGE CHIRAS**, Sarantaporou 38, 262 23 Patra, Greece.

PELOBATES SYRIACUS (Syrian Spadefoot). IRAN: MAZANDARAN PROVINCE: Bandar-e-Turkmen, ca. 36°53'N, 54°4'E, 20 m below sea level. 28 March 1991. H. G. Kami. Kami Collection No. 144 (deposited in Zoological Museum of Tehran University). Easternmost record for species; second record for Province. Extends range eastward to Caspian coast, 170 km from 14 km W Babolsar (36°41'N, 52°29'E). [Tuck 1971, Bull. Maryland Herpetol. Soc. 7:51; Eise Mus. Wien 77:182–184; Anderson 1978, Herpetol. Rev. 9(1):21].

PHYLLOMEDUSA TARSIUS (Rana Lemur). VENEZUELA: ESTADO BARINAS: Municipio Pedraza, Reserva Forestal de Caparo, "entrada de Pica 8," near Estación Cachicamo, 50 m elev. Colección de Anfibios y Reptiles, Instituto de Geografía, Universidad de Los Andes (ULABG 3973). 12 May 1995. Carlos Gottberg. First museum documented record for Venezuela (La Marca 1992, Cuadernos Geográficos 9:70–72); a single specimen of this species, from "Estado Bolívar, Venezuela" had been previously pictured in Duellman and Trueb (1986, Biology of Amphibians. McGraw Hill, New York. 670 pp.). Most probably, it belongs to a series deposited in the Herpetological Collection of the University of Kansas Museum of Natural History (KU) with the numbers KU 167189–16200, coming from "Bolívar, 13 km S, 1 km E Puente Cuyuní, 140m," which would be the nearest previously known locality. This is the first record for the state of Barinas, and the northernmost record for the taxon.

Submitted by **ENRIQUE LA MARCA**, Universidad de Los Andes, Facultad de Ciencias Forestales, Instituto de Geografía y Conservación de Recursos Naturales, Apartado Postal 116, Mérida 5101–A, Venezuela.

PSEUDACRIS TRISERIATA (Western Chorus Frog). USA: COLORADO: MONTROSE CO: 2.5 km W Oak Grove (N 1/2 Sec. 3, T48N, R10W) in flooded pool adjacent to the Montrose and Delta Canal. 21 May 1996. J. Kehmeier, C. Wagner, and L. J. Livo. UCM 57780. Verified by H. M. Smith. First record for county (Livo et al. 1996 Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Colorado Herptol. Soc. 22 pp.). Several additional localities for this species in Montrose County were reported during aural surveys on 21 May 1996, including: 5 km W and 2 km N Oak Grove (SE 1/4 Sec. 28, T49N, R10W) by JK, CW, and LJL; 6 km W and 6 km N Oak Grove (NE 1/4 Sec. 16, T49N, R10W) by JK, CW, and LJL; and 6 km W and 7 km N Oak Grove (SW 1/4 Sec. 9, T49N, R10W) by John Alves, Greg Policky, and David Chiszar. These surveys were conducted as part of a Colorado Division of Wildlife amphibian and reptile workshop coordinated by John Alves.

Submitted by **JON KEHMEIER, CRISTI WAGNER,** and **LAUREN J. LIVO,** Colorado Division of Wildlife, 317 West Prospect, Fort Collins, Colorado 80526-2097, USA.

RANA CAMERANI (Caucasus Frog). IRAN: CHAHAR MAHAL BAKHTIARI PROVINCE: Daymeh Spring, 20 km E Kouhrang, 32°26'N, 50°6'E, 2060 m elev. 28 July 1994. H. G. Kami and Parsa; 25 km from Gandoman (60 km to Lordegan [Sulgan River]), ca. 31°30'N, 50°50'E, 1580 m elev. 29 July 1994. H. G. Kami and Parsa; around Chaghakhor Lake, ca. 31°52'N, 50°56'E, 2060 m elev. 30 July 1994, H. G. Kami and Parsa. Field Nos. 1–10, Baluch Collection in Tehran University, 10 specimens. All records are southernmost for Iran.

Submitted by **HAJI GHOLI KAMI** and **EBRAHIM VAKILPOURE**, Department of Biology, Faculty of Sciences, Agricultural Sciences and Natural Resources of Gorgan University, Iran.

RANA MACROCNEMIS PSEUDODALMATINA (Iranian Brusa Frog). IRAN: ARDABIL PROVINCE: 45 km SE Khalkhal, Yeilagh-e-Sarasi, Delmadeh village, ca. 37°36'N, 48°31'E, 1500 m elev. 5 September 1991. H. G. Kami and M. Khoshchin. MMTT 2135–2136. Westernmost record in Iran. MAZANDARAN PROVINCE: Daraz nou, 24 air km SW Gorgan, ca. 36°5'N, 54°8'E, 2644 m elev. 5 August 1994. H. G. Kami and M. Firouznia. Deposited in Department of Environment, College in Karaj (cat. no. pending). Record elevation in Iran.

RANA PALUSTRIS (Pickerel Frog). USA: LOUISIANA: AVOYELLES PARISH: Yellow Bayou at Simmesport. 26 March 1994. Michael Milliet. Ernest A. Liner Collection (EAL 5229, 1 specimen). Verified by Harold A. Dundee. Fills distributional gap from West Feliciana Parish and Rapides Parish, being intermediate and a new parish record as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA.

TESTUDINES

APALONE SPINIFERA PALLIDA (Pallid Spiny Softshell). USA: LOUISIANA: ALLEN PARISH: Calcasieu River, ca. 5 km S of Rt. 26 near Oberlin. 11 July 1995. Deposited at the University of Canberra, Australia (UC 0340). Verified by Brian I. Crother. New parish record; eggs collected from river sandbars and hatched in the laboratory.

Submitted by **J. SEAN DOODY**, Applied Ecology Research Group, University of Canberra, P.O. Box 1, Belconnen, ACT 2616, Australia, and **RICHARD E. ANDERSON** and **CLIFF S. RICHARDSON**, Department of Biological Sciences, Southeastern Louisiana University, SLU 814, Hammond, Louisiana 70402, USA.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). CANADA: ONTARIO: ESSEX CO: East Sister Island, Lake Erie (UTM 17TLS 457 304). 16 July 1992. Raymond A. Saumure and David Kraus. Verified by Ross MacCulloch. ROM Kodachrome Slide 26940. First record from island and furthest record from mainland (King 1987, J. Herptol. 21:65–67). Found in a shallow pond formed due to the high water level of Lake Erie during 1992.

Submitted by **RAYMOND A. SAUMURE**, Department of Natural Resource Sciences, McGill University, 21111 Lakeshore Road, Ste-Anne-de-Bellevue, Quebec, H9X3V9, Canada.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: TEXAS: FLOYD CO: 2 km E Barwise. 22 September 1995. James T. Anderson and Ann M. Anderson. The Museum of Texas Tech University (TTU 11494). Verified by Frank Yancey. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 434 pp.) Turtle was located in a flooded playa wetland which had been previously dry for two months.

Submitted by **JAMES T. ANDERSON** and **ANN M. ANDERSON**, Department of Range, Wildlife, and Fisheries Management, Texas Tech University, MS 2125, Lubbock, Texas 79409-2125, USA.

EMYDOIDEA BLANDINGII (Blanding's Turtle). USA: INDIANA: WAYNE CO: ca. 3.1 mi NNE Williamsburg in Greensfork River, Green Township, NW 1/4 NW 1/4 Sec. 28, T18N, R14E, 100 m downstream from Sec. 21. 20 February 1996. A. McConaha, M. McConaha and D. McConaha. Verified by Joseph T. Collins. Photographed (UF 103394, 3 slides); also photographed for The Palladium Item, Richmond, Indiana, 6 March 1996 (evening edition); released at capture site. Extralimital record; ca. 47 km southeast of nearest known extralimital locality in Delaware County, Indiana, ca. 92 km due east of extralimital locality in Marion County, Indiana, and ca. 138 km southeast of the nearest record from the continuous range for the species in Wabash County, Indiana (Minton 1996, Amphibians and Reptiles of Indiana. Second ed. Indiana Acad. Sci., *in press*). Possibly an introduction, although its record size (female, 274 mm maximum carapace length; 268 mm maximum plastron length; 2550 g body mass; previous record, 273 mm carapace length in Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin, Boston, Massachusetts. 450 pp.) and remote location argue that it might be a natural relict.

Submitted by **JOHN B. IVERSON**, Department of Biology, Earlham College, Richmond, Indiana 47374, USA.

GRAPTEMYS BARBOURI (Barbour's Map Turtle). USA: FLORIDA: GADSDEN CO: Ochlockonee River, 5.3 km straight-line distance S of U.S. Rt. 27 bridge. 26 May 1993. R. L. Cailteux and J. J. Nordhaus. Verified by David L. Auth. UF 91087. First record outside of the Apalachicola River drainage. A juvenile *G.*

barbouri (CL = 45.9 mm; PL = 35.5 mm; mass = 11.5 g) also was collected by electrofishing in the Ochlockonee River, 0.8 km straight-line distance S of U.S. Rt. 27 bridge. On 1 June 1994, Daniel A. Dobbins collected a basking *G. barbouri* (CL = 53.4 mm, PL = 46.7 mm, mass = 30.1 g) at Stoutamire Landing, 4 km straight-line distance SW of Fla. Rt. 20 bridge along the Liberty/Leon County line (UF 91086). The first two collecting locales are ca. 7.4 river km apart and upstream of Lake Talquin, a 3200-ha reservoir, whereas the third locality is downstream of Lake Talquin. During the Pleistocene, this species may have ranged eastward into the Suwannee River drainage (Jackson 1975, Herpetologica 31:213–219), but it is thought to now be confined to large and medium-sized rivers emptying into Apalachicola Bay. The mouths of the Apalachicola and Ochlockonee rivers are separated by >100 km of shoreline, primarily beach. Brackish coastal marshes between river mouths provide effective barriers to Graptemys (Wood 1977, J. Herpetol. 11:415–421). The source of these *G. barbouri* may have been Telogia Creek, the principal western tributary of the Ochlockonee River, which approaches within 0.6 km of the Apalachicola River drainage and appears to have been once a tributary of the Apalachicola River, although the disparity in fish faunas between the two river systems indicates long-term physiographic independence (Gilbert 1987, Brimleyana 13:25–54). If this species is not indigenous to the Ochlockonee River, it was introduced by humans. This species is not commonly kept in captivity because Florida prohibited commercial trade >15 years ago, although Florida allows the personal possession of two *G. barbouri*. The first two collecting sites are just W of Tallahassee, and three major highway crossings occur in the vicinity. There is only one highway crossing within 5 river km of the site of the third specimen, which was found downstream of the Jackson Bluff dam constructed in 1929 to form Lake Talquin. The small size of these specimens indicates that reproduction is occurring, because the release, survival, and subsequent recapture of three such specimens are unlikely.

Submitted by **KEVIN M. ENGE, RICHARD L. CAILTEUX**, and **JEFFERY J. NORDHAUS**, Florida Game and Fresh Water Fish Commission, Route 7, Box 3055, Quincy, Florida 32351, USA.

GRAPTEMYS PULCHRA (Alabama Map Turtle). USA: MISSISSIPPI: Noxubee Co: Noxubee River, 29.3 river km upstream of Alabama border, NW 1/4 Sec. 4, T13N, R18E. 16 August 1994. T. C. Majure, R. L. Jones, and C. L. Knight. Adult male and juvenile. Mississippi Museum of Natural Science (MMNS 298502986). Clay Co: Tibbee Creek, 4.5 river km upstream of confluence with Catalpa Creek, SE 1/4 Sec. 33, T17S, R7E. 21 August 1995. T. C. Majure, R. L. Jones, and C. L. Knight. Adult male. MMNS 3235. Both verified by T. L. Vandeventer. Confirms presence of species in Tombigbee River system within Mississippi (Ernst et al. 1994, Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 578 pp.)

Submitted by **ROBERT L. JONES, TERRY C. MAJURE,** and **CHARLES L. KNIGHT**, Mississippi Department of Wildlife, Fisheries, and Parks, and Museum of Natural Science, 111 North Jefferson Street, Jackson Mississippi 39201, USA.

KINOSTERNON ODORATUM (Common Musk Turtle). USA: TEXAS: Rains Co: Lake Tawakoni near the Sabine River Authority Headquarters; shell at the edge of the lake, ca. 5 km S of Hermits Cove. 10 December1995. R. L. Gutberlet, Jr. and C. L. Stewart. Verified by J. A. Campbell. University of Texas at Arlington Collection of Vertebrates (UTA-R 39816). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, 434 pp.)

Submitted by **RONALD L. GUTBERLET, JR.** and **CAROL L. STEWART**, Department of Biology, the University of Texas at Arlington, Arlington, Texas 76019, USA.

STERNOTHERUS CARINATUS (Razorback Musk Turtle). USA: LOUISIANA: Terrebonne Parish: Houma. 3 June 1981. Ernest A. Liner. Ernest A. Liner Collection (EAL 4803, 1 specimen). Verified by Harold A. Dundee. First record for the parish; extends the range south 43 mi (77.2 km) from that mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA.

PSEUDEMYS TEXANA (Texas River Cooter). USA: TEXAS: Brazos Co: Lake Placid, 60 km S Bird Pond Road and 1 mi E Rock Prairie Road, E of Texas Rt. 6. Caught in minnow trap along N-S Dam on east end of lake. 17 March 1996. Mitchell A. Lockwood. Verified by James R. Dixon. Texas Cooperative Wildlife Collection (TCWC 72432, juvenile). New county record (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **R. KATHRYN VAUGHAN** and **MITCHELL A. LOCKWOOD**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843-2258, USA.

TRACHEMY SCRIPTA ELEGANS (Red-eared Slider). USA: SOUTH CAROLINA: Pickens Co: landlocked arm of the former Seneca River adjacent to athletic practice field, Perimeter Road, ca. 0.75 km SW of jct. S.C. Rt. 93, Clemson University Campus, Clemson. 7 September 1995. Steven G. Platt. Verified by Stanlee Miller. Campbell Museum (CUSC 1278). Eight turtles captured in three trap nights. Other turtles, both juveniles and adults observed basking. Appears established at this site. Population is believed to have originated from released pets. State record. *Trachemys scripta elegans* not previously reported as established in South Carolina. *Trachemys scripta scripta* present 75 km S in Abbeville County (Martof et al. 1980, Amphibians and Reptiles of the Carolinas and Virginia. Univ. North Carolina Press, Chapel Hill. 264 pp.).

Submitted by **STEVEN G. PLATT,** Department of Biological Sciences, Clemson University, Clemson, South Carolina 29634-1903, USA, and **WILLIAM E. SNYDER**, Center for Ecology, Evolution, and Behavior, and Department of Entomology, S-255 Agricultural Science Building, University of Kentucky, Lexington, Kentucky 40546-0091, USA.

LACERTILIA

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: Franklin Co: St. George Island, private residence in 600 block of West Bayshore Drive. 25 July 1995. Woodard Miley II. Verified by David Auth. UF 103501. New county record and first record for a northern Gulf of Mexico barrier island (Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9). Apparently, this population was founded when a large number of potted plants were imported for landscaping from near Clearwater in central Florida, in a manner similar to the mode of establishment of the population at Barnacle Bay Mini-Golf course in Panama City Beach (Means 1990, Herpetol. Rev. 21:96). Woody Miley and local residents reported that in summer 1995 *A. sagrei* was very abundant on the property (about 25 individuals seen), but on 27 May 1996 we were able to find only three individuals. One specimen of the green anole (*A. carolinensis*) was also seen. Additional specimens

were not collected because the population apparently suffered some mortality during the cold and long-lasting winter of 1995–1996. Significantly, some individuals obviously survived the cold winter (temperatures to 7°C) as well as saltwater that overwashed St. George Island from Hurricane Opal on 3 October 1995.

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute, 1313 North Duval Street, Tallahassee, Florida 32303, USA.

EUMECES LATICEPS (Broadhead Skink). USA: LOUISIANA: TERREBONNE PARISH: Houma. 26 April 1969. Ernest A. Liner. Ernest A. Liner Collection (EAL 2347, 1 specimen); Houma. 5 March 1969. Jerry Gautreaux. EAL 2354 (1 specimen); Houma. 5 May 1973. Steve Pizollata. EAL 3611 (1 specimen); Houma. 5 May 1974. Jerry Gautreaux and Maurice Prosperie. TCWC 71393 (1 specimen); Houma. 5 December 1982. Ernest A. Liner. All verified by Harold A. Dundee. First records for the parish; extend the range 15 mi (24.1 km) south from that mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.)

Submitted by **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA.

EUMECES OBSOLETUS (Great Plains Skink). USA: TEXAS: FLOYD CO: Caprock Canyons Trailways State Park, UTM coordinates 14 305689E 3794462N. 4 May 1996. F. D. Yancey, II and K. J. Roberts. Verified by Clyde Jones. The Museum of Texas Tech University (TTU 11534). New county record; fills gap between Hale and Motley counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II** and **KRISTIE JO ROBERTS**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

GEKKO GECKO (Tokay Gecko). USA: FLORIDA: LEON CO: Tallahassee, 1300 block between Milton and Jackson Streets. Photograph of adult taken in late summer 1994 by Robert Dahlstrom. Verified by David Auth. UF 103506. Photographs of two young individuals taken in summer 1995 by Robert Dahlstrom. Verified by David Auth. UF 103507. New county record and first record of a breeding population outside of south peninsular Florida. During five successive springs (1992–1996), I heard vocalizations (first since winter on 12 April 1994, 30 March 1995, and 22 April 1996) from at least one large individual from trees and walls of the same house, indicating that one adult gecko has survived at least four successive winters, including the very cold and long winter of 1996. On 25 April 1996, I saw a large individual on my house at the same time that I heard another individual vocalizing about 75 m away. Throughout the month of May 1996, I heard two different geckos vocalizing from two different houses. Local residents said that tenants of a duplex on Milton Street released at least two *Gekko gecko* for pest control about 1990 or 1991. The discovery of two recently-hatched young in the summer of 1995 attests to successful natural reproduction in this species at a latitude of 30°N. Apparently a small breeding population is established.

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute, 1313 North Duval Street, Tallahassee, Florida 32303, USA.

HEMIDACTYLUS GARNOTTII (Indo-Pacific Gecko). USA: TEXAS: DALLAS CO: Dallas. Specimen captured inside herpetarium at the Dallas Zoo; one other was found but not captured. 16 February 1996. Carl J. Franklin. Verified by Ron Gutberlet. The University of Texas at Arlington Collection of Vertebrates (UTA R-39756). New state record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). This lizard has established itself inside the herpetarium; several adults and hatchlings have been observed and collected. However, this species was never intentionally acquired by the Dallas Zoo and probably arrived with plants purchased from Florida.

Submitted by **CARL FRANKLIN**, Dallas Zoo and Aquarium, Reptile Department, 621 East Clarendon Drive, Dallas, Texas 75203, USA, and Department of Biology, Box 19498, The University of Texas at Arlington, Arlington, Texas 76019-0498, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: FLORIDA: FRANKLIN CO: City of Apalachicola: Fish market at 12th Street and Avenue E (U.S. Rt. 98). One specimen collected 27 May 1996 by Thomas Evans and D. B. Means. Verified by David Auth. UF 103502. Residents of Apalachicola claimed they have seen the Mediterranean Gecko on buildings around town (e.g., Apalachicola Times Building, 265 North Water Street) since at least 1991. Woodard Miley II first reported the fish market occurrence to me in March 1996. The specimens reported here verify that this species survived the cold winter of 1995–1996. New county record and first record for the city of Apalachicola; this record helps close the gap in the northeastern Gulf coastal distibution of this species between Panama City and Tampa (Nelson and Carey 1993, Northeast Gulf Sci. 13(1):53–58).

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute, 1313 North Duval Street, Tallahassee, Florida 32303, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: LOUISIANA: ST. TAMMANY PARISH: adult male captured on the window of a building at the KOA campground on Rt. 433 near Slidell. 21 May 1996. Verified by Richard L. Holland. Slides of specimen in University of Colorado Museum Photographic Collection (UCM 122–126). Species was previously known from only four parishes in the state, including two parishes south of Lake Pontchartrain (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.). Parish record; extends known range to the north of Lake Pontchartrain.

Submitted by **GREGORY J. WATKINS-COLWELL**, Connecticut Audubon Coastal Center, 1 Milford Point Road, Milford, Connecticut 06460, USA, **KELLIE A. WATKINS-COLWELL**, St. Joseph Medical Center, 128 Strawberry Hill Avenue, Stamford, Connecticut 06904, USA, and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

OPHIOMORUS PUNCTATISSIMUS (Greek Snake Skink). GREECE: STEREA ELLADA: Prefecture of Aitolia and Akarnania: Province of Nafpaktia: ca. 2 km SE of Palaiopyrgos village, 38°28'57"N, 21°51'47"E, ca. 480 m elev. 9 July 1995. D. P. Papandropoulos and B. P. Chondropoulos. Verified by E. Valakos. Zoological Museum of University of Patra (ZMUP A-R 1375). The species is hitherto known from eastern part of central Greece (Sterea Ellada), Peloponnisos (except its northwestern part) and the island of Kythira (Bischoff 1981, pp. 366–372. In Bohme (ed.), Handbuch der Reptilien und Amphibien Europas, Band 1, Akad. Verlagsges., Wiesbaden; Bringsøe 1985, Ann. Musei Goulandris 7:271–318; Chondropoulos 1986, Amphibia-Reptilia 7:217–235). First record for the whole western part of the central and northern Greek mainland, extending range by ca. 118 km

(direct line distance) WSW of the nearest known limit of distribution in the region of Sterea Ellada (Malesina village, Fthiotida Prefecture) as recorded by Bischoff (*op. cit.*). Because *O. punctatissimus* is distributed only in SW Turkey and Greece, our record also constitutes a western extension of the entire range of the species.

Submitted by **BASIL P. CHONDROPOULOS**, Section of Animal Biology, Department of Biology, University of Patra, 260 01 Patra, Greece, and **DIMITRIS P. PAPANDROPOULOS**, Zaimi 21, Rio, 265 00 Patra, Greece.

PETROSAURUS REPENS (Shortnose Rock Lizard). MÉXICO: BAJA CALIFORNIA SUR: Cañon de Los Reyes, 37 km north of La Paz. L. Lee Grismer and Clark R. Mahrdt. Verified by Bradford D. Hollingsworth. LACM PC 1326. Several specimens were observed on 16 and 17 October 1994 crawling on the steep, rocky walls of the canyon. This extends its distribution southward ca. 63 km through the Sierra de La Giganta (Jennings 1990, Cat. Amer. Amphib. Rept. 496.1–496.3) and brings it to within ca. 55 km of its closest relative *P. thalassinus* of the Cape Region (Jennings, *op. cit.*).

Submitted by **L. LEE GRISMER,** Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, and **CLARK R. MAHRDT,** Southwestern Biologists, 9847 Willow Lane, Escondido, California, 92092, USA.

SCELOPORUS CHANEYI (Chaney's Spiny Lizard). MÉXICO: TAMAULIPAS: 0.5 km SE summit Sierra La Gloria off La Pena-Valle Hermoso Road, 21.1 km N jct. with La Pena-Miquihuana Road, elev. 3018.3 m. On fallen pine needles and in low *Ceanothus* at edge of meadow. 1 September 1986. J. F. Copp, D. E. Breedlove, R. R. Riviere and B. R. Anderson. CAS 165250–2. Verified by Richard L. Holland. First record for the state of Tamaulipas (Liner and Dixon 1992, Texas J. Sci. 44:422); previously known only from closely adjacent Nuevo Leon in the vicinity of Sierra Pena Nevada.

Submitted by **GREGORY J. WATKINS-COLWELL**, Department of Biology, Sacred Heart University, Fairfield, Connecticut 06432-1000, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA.

SCELOPORUS SCALARIS SCALARIS (Highlands Bunch Grass Lizard). MÉXICO: NAYARIT: Ocote airstrip, 2119 m, 21°03'N 104°14'W. 18–19 July 1983. Timothy W. Houseal. TCWC 61714. New state record and a known range extension northwestward of 130 km from the vicinity of Tapalpa, 2256 m, Jalisco (Smith and Hall 1974, Great Basin Nat. 34:103); ten critically conformant specimens are available (UTA 4018–22, 4815–18, 11786). Verified by Richard L. Holland.

Submitted by **GREGORY J. WATKINS-COLWELL**, Department of Biology, Sacred Heart University, Fairfield, Connecticut 06432-1000, USA; **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA.

SCELOPORUS SCALARIS UNICANTHALIS (Smith's Bunch Grass Lizard). MÉXICO: DURANGO: 21 air km S and 12 air km W Teneraca, 2040 m. 27 November 1970. Robert G. Webb. UTEP 7408–10 (29, 31, 34 mm SVL); near Huazamota on trail to Santa Teresa (Nayarit). 13 August 1897. Edward W. Nelson and Edward A. Goldman. USNM 46626 (47 mm SVL). All are immatures, but they provide the first records for Durango (Smith and Hall 1974, Great Basin Nat. 34:103) and a northward range extension of about 150 km on the west slopes of the Sierra. Those from Teneraca were found in a hilly, grassy area with scattered oak and pine, and small rock outcrops; one *Anolis nebulosus* was obtained at the same time and place. Substantiated by UTEP 7417 from nearby northern Nayarit (previously recorded in Nayarit only from the extreme south, *loc. cit.*), 1 air km S and 27 air km E Huajicori, 1465 m, 3 December 1970, Robert G. Webb. All verified by Richard L. Holland. The other two subspecies in Durango occur only on eastern slopes—*S. s. slevini* in the extreme north, *S. s. scalaris* in central and southern parts.

Submitted by **ROBERT G. WEBB**, Department of Biological Sciences, University of Texas at El Paso, El Paso, Texas 79968-0519, USA; **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA; and **GREGORY J. WATKINS-COLWELL**, Department of Biology, Sacred Heart University, Fairfield, Connecticut 06432-1000, USA.

TROPIOCOLOTES LATIFI (Latifi's Sand Gecko). IRAN: FARS PROVINCE: Shiraz Mountains around Salt Lake, ca. 29°36'N, 52°33'E, 1495 m elev. 26 March 1996. Zahra Mottaghi. Zoological Museum of Gorgan University (ZMGU 100).

Submitted by **HAJI GHOLI KAMI** and **EBRAHIM VAKILPOURE**, Department of Biology, Faculty of Sciences, Agricultural Sciences and Natural Resources of Gorgan University, Iran.

UTA STANSBURIANA STEJNEGERI (Desert Side-blotched Lizard). USA: TEXAS: Floyd Co: Caprock Canyons Trailways State Park, UTM coordinates 14304503E 3790783N. 9 May 1996. F. D. Yancey II and K. J. Roberts. Verified by Clyde Jones. The Museum of Texas Tech University (TTU 11536). New county record; fills gap between Briscoe and Crosby counties, and helps define western limit of this taxon in the Texas panhandle (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II** and **KRISTIE JO ROBERTS**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

AMPHISBAENIA

RHINEURA FLORIDANA (Florida Worm Lizard). USA: GEORGIA: Lanier Co: Patten's Seed Company, ca. 5 mi N of Lakeland. 10 April 1974. J. A. Payne. Verified by Joshua Laerm. University of Georgia Museum of Natural History (UGAMNH Photo 24899). New state record (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.) for this previously recognized Florida endemic. Extends its known range ca. 75 km N of northernmost locality in Florida (Meylan 1984, Herpetol. Rev. 15:23–24). Individual was collected from a sapling pecan tree planting hole. Specimen was donated to Gerald E. Cosgrove, pathologist at Oak Ridge National Laboratory, who has since deceased. His collection was later donated to the San Diego Museum of Natural History, but the specimen was apparently lost prior to being cataloged.

Submitted by **JOHN B. JENSEN** and **JERRY A. PAYNE**, Georgia Department of Natural Resources, Wildlife Resources Division, Nongame Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

SERPENTES

CROTALUS ATROX (Western Diamondback Rattlesnake). USA: TEXAS: HALL CO: Caprock Canyons Trailways State Park, UTM coordinates 14325866E 3809386N. 9 May 1996. F. D. Yancey. Verified by Clyde Jones. The Museum of Texas Tech University (TTU 11535). New county record; fills gap between Briscoe and Childress counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). USA: TEXAS: ANDREWS CO: 14 km N Andrews. 22 May 1960. Tinkle. The Museum of Texas Tech University (TTU 1468); 6 km SW Andrews. 30 June 1960. McGregor and Patterson. TTU 1821; 30 km SW Andrews. 28 May 1961. Tinkle. TTU 2506; 25 km SW Andrews. 2 June 1961. Tinkle. TTU 2588; 7 km S Rt. 115 on Rt. 181. 9 May 1962. B. Hutchison. TTU 3189. All specimens verified by Clyde Jones. New county records; fill gap between Yoakum and Terry counties to the north, and Winkler and Ector counties to the south (Dixon 1987, Amphibians and Reptiles of Texas). Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

DIADOPHIS PUNCTATUS ARNYI (Prairie Ringneck Snake). USA: TEXAS: KENT CO: 3.2 km S Clairemont. 5 May 1968. Don and David Forester. Verified by Clyde Jones. The Museum of Texas Tech University (TTU 4450). New county record; helps define the range of this subspecies in Texas. Also, may aid in clarifying possible zone of contact with *D. p. regalis* (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

DRYMARCHON COUPERI (Eastern Indigo Snake). USA: GEORGIA: LIBERTY CO: St. Catherine's Island. August 1983. John Couper. Verified by Frank van Breukelen. UCM Color Slide 114. First confirmed record for any of Georgia's barrier islands, although a sighting has been reported for Sapelo Island (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Publ. No. 2; range map for *D. couperi* annotated by J. T. Collins, pers. comm. 1996).

Submitted by **JOHN COUPER**, University of Wisconsin, Madison, Wisconsin 53706, USA, Gwen Murdock, Missouri Southern State College, Joplin, Missouri 64801, USA, **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309, USA.

GYALOPION CANUM (Western Hooknose Snake). USA: TEXAS: GARZA CO: Justiceburg Wildlife Management Area, 5 km N and 15 km E Justiceburg. 17 June 1993. F. D. Yancey, II. Verified by Clyde Jones. The Museum of Texas Tech University (TTU 11528). New county record; defines western margin of the northern portion of the range of this species in Texas (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II,** Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

HYDROPHIS TORQUATUS DIADEMA (West Coast Blackhead Sea Snake). CAMBODIA: TONLE SAP: Km 9. Collected by fishermen in nets and given to F. d'Aubenton. February 1962. Museum national d'Histoire naturelle, Paris (MNHN 1963. 743–744). Verified by Arne Rasmussen. New country record. First determined as *Hydrophis* sp. with a precise description of both specimens (Saint Girons 1972, Mem. Mus. natn. Hist. nat., ser. A, tome 74:1–170) and later as *Hydrophis mamillaris* in MNHN collections by R. Roux. Previously known only from Meklong (bight of Bangkok) on the west side of the Gulf of Thailand to Koh Chang Island on the east side of the Gulf of Thailand and considered as particularly abundant at the mouths of the Meklong and the Chanthaburi rivers (Smith 1926, British Mus. (Nat. Hist.), London. xvii + 130 pp.; Taylor 1965, Univ. Kansas Sci. Bull. 45(9):609–1096). Collecting data do not permit a determination as to whether these specimens correspond to established populations, migratory populations, or just to isolated individuals (Saint Girons, *op. cit.*).

Submitted by **IVAN INEICH**, Museum national d'Histoire naturelle, Laboratoire de Zoologie (Reptiles & Amphibiens), 25 rue Cuvier, F-75005 Paris, France.

LIOCHLOROPHIS (=OPHEODRYS) VERNALIS (Smooth Green Snake). USA: COLORADO: MESA CO: Colbran, in town park (NE 1/4 Sec. 35, T9S, R95W). 20 May 1996. L. J. Livo and David Chiszar. UCM 57782. First record for county (Livo et al. 1996. Colo. Herptol. Soc. 22 pp.). Verified by Roseanne Humphrey.

Submitted by **LAUREN J. LIVO**, Colorado Division of Wildlife, 317 West Prospect, Fort Collins, Colorado 80526-2097, USA; **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA; and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

MASTICOPHIS FLAGELLUM TESTACEUS (Western Coachwhip). USA: TEXAS: FLOYD CO: Caprock Canyons Trailways State Park, UTM coordinates 14 304503E 3790783N. 23 May 1996. F. D. Yancey, II and K. J. Roberts. Verified by Clyde Jones. The Museum of Texas Tech University (TTU 11537). New county record; fills gap between Briscoe and Crosby counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **FRANKLIN D. YANCEY, II** and **KRISTIE JO ROBERTS**, Department of Biological Sciences and the Museum, Texas Tech University, Lubbock, Texas 79409-3191, USA.

PHILODRYAS AESTIVUS SUBCARINATUS (Brazilian Green Racer). ARGENTINA: CORDOBA: DEPARTMENT RIO CUARTO: Rio Cuarto (Ba. Universidad, Las Higueras, 33°06'S, 64°18'W). 24 July 1995. Collector unknown. Verified by Ricardo A. Martori. Herpetological collection of Orientacion Zoologia de Vertebrados, Departamento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Argentina (ZV-UNRC 3639). First departmental record, second record in Cordoba province, and a westward extension of the known range ca. 50 km from previous citation (Corbella, Bol. AHA 5(1–2):11–12).

Submitted by **LUCIANO JAVIER AVILA**, CONICET—Departamento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Est. Post. 9, C.P. 5800, Rio Cuarto (Cordoba), Argentina.

REGINA SEPTEMVITTATA (Queen Snake). USA: GEORGIA: BALDWIN CO: Champion Creek, 3.4 km N Lake Laure Road and St. Rt. 22. 26 September 1993. Gregory B. Lacy. Verified by Den-

nis Parmley. Georgia College (DCP-GC 3784). Adult female captured in a minnow trap in Champion Creek below Lake Laurel. First county record; fills a central Georgia distribution gap (Williamson and Moulis 1994, Savannah Sci. Mus. Spec.Publ. No. 3).

Submitted by **GREGORY B. LACY**, Department of Biological and Environmental Sciences, Georgia College, Milledgeville, Georgia 31061, USA.

RHINOBOTHRYUM LENTIGINOSUM (Coral Falsa). VENEZUELA: ESTADOS BOLÍVAR: Km 88, Carretera el Dorado–Santa Elena de Uairén. 8 August 1983. Luis Duque. Verified by Celsa Señaris. Museo de Ciencias Naturales de Caracas (MCNC–6387, female). First record of this snake and second species of the genus cited for Venezuela. Captured in tropical rain forest at night [Pons 1965, Kasmera, 2(1):99–103; Roze 1966, La Taxonomía y Zoogeografía de los Ofidios de Venezuela, UCV. 343 pp.; Lancini 1979, Serpientes de Venezuela. Verlag Armitano. 262 pp.; Lancini and Kornacher 1989, Die Schlangen von Venezuela. Verlag Armitano. 381 pp.].

Submitted by **CESAR R. MOLINA R.**, Curator of Herpetology, Museo de Ciencias Naturales de Caracas, Calle Comercio, sector Peaje, Las Acacias, Caracas, D.F., Venezuela, and **GILSON A. RIVAS F.**, Museo de Historia Natural La Salle, Assistant Section Herpetology, P.O. Box 1930, Caracas, 1010–A. Venezuela.

THAMNOPHIS EQUES (Mexican Garter Snake). USA: NEVADA: Clark Co: Lake, opposite Ft. Mohave, Arizona. 8 April 1911. Junius Henderson. Verified by David Chiszar. University of Colorado Museum (UCM 104). First state record (Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Second ed. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.) and further substantiation of the presence of this species at one time in the vicinity of the southern tip of Nevada and adjacent Arizona (Rosen and Schwalbe 1988, Rept. Arizona Game and Fish Dept. to the U.S. Fish and Wildlife Service, Albuquerque, New Mexico. 50 pp.). The somewhat ambiguous locality description apparently refers to part of the (dammed?) Colorado River as there is no town called "Lake" in the area.

Submitted by **ALAN DE QUEIROZ** and **HOBART M. SMITH**, University Museum and Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA.

TYPHLOPS ATER (Irian Worm Snake). INDONESIA: BALI: Near Samur under a stone in a yard next to a wood carving factory. 5 December 1994. Harold A. Dundee. Verified by Jeff Boundy. TU 23529. The species is known from eastern Java in the Idjen Highlands, which are ca. 10 km from Bali, and in many islands to the east of Bali (Brongersma 1934, Contributions to Indo-Australian Herpetology. E. J. Brill, Leyden.). Java is separated from Bali by ca. 2 km of ocean and *T. ater*, like many typhlopids, is easily transported amid the roots of plants.

Submitted by **HAROLD A. DUNDEE**, Tulane Museum of Natural History, Belle Chasse, Louisiana 70037-3098, USA.

VIRGINIA STRIATULA (Rough Earth Snake). USA: LOUSIANA: St. Mary Parish: Morgan City. 10 March 1971. Robert P. Blereau. Ernest A. Liner Collection (EAL 2587, 1 specimen); 24 March 1976. Blair Hardin. EAL 4037 (1 specimen). Verified by Harold A. Dundee. Extends range southward ca. 34 mi (54.7 km) from that mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Northern Range Expansion of the Brown Anole (*Anolis sagrei*) in Florida and Georgia

TODD S. CAMPBELL
Department of Ecology and Evolutionary Biology
University of Tennessee, 569 Dabney Hall
Knoxville, Tennessee 37996-1610, USA

The brown anole, *Anolis sagrei*, a native of Cuba and the Bahamas, was first recorded in North America in the Florida Keys by Garman (1887). Oliver (1950) and Bell (1953) document its arrival in the major seaports of south Florida during the 1940s. Based on museum records and numerous geographic distribution papers, this species had become firmly established in most large urbanized areas of peninsular Florida south of Gainesville by 1980 (reviewed in Godley et al. 1981 and Lee 1985), and has since been found in the Florida panhandle (Means 1990), in Louisiana (Thomas et al. 1990; Platt and Fontenot 1994), and in Texas (Dixon 1987; King et al. 1987). This species continues to move northward and establish peripheral populations in north Florida and south Georgia. Brown anoles have been present in Valdosta, Georgia since 1987 (Echternacht et al. 1995). They were recently found in central Georgia as far north as Tifton, and on the east coast as far north as Brunswick and St. Simons Island (Campbell and Hammontree 1995).

Herein I report six additional county records in northern Florida that fill gaps in the geographic range of this recent invader between populations in northern peninsular Florida (Funk and Moll 1979; Godley et al. 1981; Lee 1985; Stevenson and Crowe 1992; Wygoda and Bain 1980) and recent records in north Florida and south Georgia (Campbell and Hammontree 1995; Echternacht et al. 1995). I also provide additional records for four south Georgia counties, show that previously reported Georgia populations are surviving over winter, and provide additional evidence of vehicular transport.

FLORIDA

Hamilton County: Quality Inn (formerly Holiday Inn) at the jct. of I-75 and Fla. Rt. 143, one mile southwest of Jennings. 13 April 1995. Todd Campbell. Verified by A. C. Echternacht. University of Florida Museum of Natural History (UFMNH 101611). Adult male collected from shrubbery (*Ilex vomitoria*) near the main building. New county record. Population size estimated to be ca. 30 individuals in April and May 1995 and more than 50 individuals in July 1995. The former hotel manager was familiar with this species and stated that brown anoles occur at her residence and other residential areas near the hotel. Green anoles (*A. carolinensis*) were found throughout the hotel grounds, while *A. sagrei* were found only near the main building and pool.

Columbia County: Lake City, Holiday Inn at the jct. of I-75 and U.S. Rt. 90. 22 May 1995. Todd Campbell. Verified by A. C. Echternacht. UFMNH 101604. Adult male collected from landscaping shrubs near the hotel office. New county record. Population size estimated to be in the upper hundreds or low thousands. This species is abundant throughout the hotel grounds and is clearly an established breeding population. Brown anoles were first observed at this hotel by me during a five-month stay in 1991. The current hotel manager was familiar with this species and stated that brown anoles have been present at his nearby residence for at least two years. Green anoles are also present at this hotel site in large numbers.

BAKER COUNTY: Econolodge at the jct. of I-10 and Florida Rt. 121, two miles south of MacClenny. 13 April 1995. Todd Campbell. Verified by A. C. Echternacht. UFMNH 101609–101610. Adult male and adult female collected near the pool. New county record. Population size estimated to be ca. 20 individuals, found only to the south and west of the hotel office and by the pool. This could represent a recent colonization event, as the population is small and none was seen by the author during a two-week stay in 1991. Green anoles are also present at this site.

PUTNAM COUNTY: Downtown Palatka, Holiday Inn on U.S. Rt. 17 on the west bank of the St. Johns River. 22 May 1995. Todd Campbell. Verified by A. C. Echternacht. UFMNH 101605–101606. Adult male and adult female collected from landscaping timbers near the pool. New county record. Population size estimated to be over 100 individuals. This is very likely an established breeding population.

FLAGLER COUNTY: Downtown Bunnell, City Hall building complex on U.S. Rt. 1. 22 May 1995. Todd Campbell. Verified by A. C. Echternacht. UFMNH 101602–101603. Adult male and adult female collected from shrubbery near the City Hall building. New county record. Population size estimated to be at least 100 individuals, found throughout the City Hall grounds. This is clearly an established breeding population, and one city employee familiar with this species stated that brown anoles are present in large numbers throughout the city of Bunnell.

VOLUSIA COUNTY: Bethune Beach, at Bethune Beach County Park on U.S. A1A (Atlantic Avenue) ca. 20 km south of New Smyrna Beach. 31 May 1995. Todd Campbell. Verified by A. C. Echternacht. UFMNH 101607. Adult male with severe scoliosis collected from saw palmetto (*Serenoa repens*) near shoreline. New county record. This record is located between records to the south in Brevard County (Cochran 1990) and those to the north near Jacksonville (Lee 1985) and St. Augustine (Meylan 1977). Numerous in isolated saw palmetto clumps and on a boardwalk along the shoreline of Mosquito Lagoon. This specimen is just one member of an extremely large, contiguous population known to be present since 1989 (pers. obs.), members of which are found at nearly every residential, commercial, and resort property in the New Smyrna Beach area between Ponce Inlet and Canaveral National Seashore.

VOLUSIA COUNTY: Canaveral National Seashore at the Turtle Mound Archaeological Site, ca. 15 miles south of New Smyrna Beach. 30 May 1995. Todd Campbell. Verified by A. C. Echternacht. UFMNH 101608. Adult male collected from natural vegetation along the shore of Mosquito Lagoon. Additional Volusia County record and first Canaveral National Seashore record. Brown anoles are found along edges of natural vegetation in Canaveral Natural Seashore at most of the beach-side boardwalks and parking areas along U.S. A1A, on the Mosquito Lagoon side of the park between the park entrance and Eldora, and on dredge spoil islands associated with the Intracoastal Waterway within Mosquito Lagoon. The fact that landscaping vegetation is not utilized in the park is strong evidence that Brown anoles are reaching the park exclusively on recreational vehicles. Urban areas directly north of this park (e.g., New Smyrna Beach and Bethune Beach) are heavily infested with brown anoles. Tourists and residents travelling from Orlando (also heavily infested) regularly seek this National Seashore because of its secluded beaches. Brown anoles reach dredge spoil islands either by riding on boats that have been stored on land or by riding on the firewood piles transported on these boats by overnight campers. Every overnight camper interviewed on these islands in 1995 stated that they stored their boat on a trailer on land, transported their own firewood, lived in areas infested with brown anoles (usually Orlando), and often found both *A. carolinensis* and *A. sagrei* on their boat and wood piles at home. A gravid female *A. sagrei* was found on a camper's wood pile in spring 1995, during which a large group of boat-campers utilized the island. Prior to that day, this island had been extensively surveyed for *A. carolinensis* as part of an ongoing research project, but no *A. sagrei* had been found. In fact, nearly every spoil island along the Intracoastal Waterway in the Indian River south of Melbourne contains dense populations of *A. sagrei* (pers. obs.). Given the above, it seems inevitable that this species will eventually reach many natural areas of Florida regardless of their degree of isolation.

GEORGIA

LOWNDES COUNTY: Valdosta, Holiday Inn at the jct. of I-75 and U.S. Rt. 84. 3 July 1995. Todd Campbell. Verified by A. C. Echternacht. University of Georgia Museum of Natural History (UGAMNH 24868). Collected adult male in a shrub near hotel office. The second population documented for Valdosta (Echternacht et al. 1995). More than 50 were observed during a brief search of the hotel grounds. This hotel is directly across the street from the Best Western hotel where the first record from Valdosta was obtained (Echternacht et al. 1995). The Best Western brown anole population has expanded to the trailer campground immediately to the west of that hotel.

TIFT COUNTY: Tifton, Holiday Inn at the jct. of I-75 and U. S. Rt. 82. 27 April 1995. Todd Campbell. Verified by A. C. Echternacht. UGAMNH 24871. Adult female collected from landscape shrubs near the main building. The second record for Tifton (Campbell and Hammontree 1995), however, only one individual was observed (and collected) at the first Tifton site in 1994, and no brown anoles were found at that site in April 1995, so this record may represent the sole population occurring in this county at this time. More than 20 were observed in shrubs near the office, restaurant, and pool. Likely represents a recently established population, as no brown anoles were observed during a thorough search of the hotel grounds in August 1994. Green anoles were numerous at this hotel on this date and in August 1994.

CAMDEN COUNTY: Kingsland, Best Western at the jct. of I-95 and Ga. Rt. 40. 4 July 1995. Todd Campbell. Verified by A. C. Echternacht. UGAMNH 24870. Adult male collected from landscape shrubs near the main building. The second record for Camden County (Campbell and Hammontree 1995). The population consists of at least 100 individuals. Of the four major hotels at this intersection, this is the only one supporting brown anoles, whereas all four support large *A. carolinensis* populations.

GLYNN COUNTY: Brunswick, HoJo hotel at the jct. of I-95 and U. S. Rt. 341. 4 July 1995. Todd Campbell. Verified by A. C. Echternacht. UGAMNH 24869. Adult male collected from landscape shrubs near the main building. The third record for Glynn County (Campbell and Hammontree 1995). The population consists of hundreds of individuals on the properties of this hotel, the Budgetel hotel and the Cracker Barrel restaurant, which are separated only by parking areas containing landscaped islands. The owner was familiar with this species and indicated that brown anoles have been present for over two years. Green anoles are also present at all of the hotels in this complex.

Vehicular rafting and transport in ornamental vegetation were first hypothesized by Godley et al. (1981) to explain the rapid dispersal of this species. Evidence of vehicular rafting was seen at Interstate rest stops and welcome centers along both I-75 and I-95. These facilities accommodate vehicles travelling in only one direction: northbound or southbound. These facilities usually lie across the interstate from one another, are constructed at the same time and are planted with similar vegetation. During surveys in 1994 and 1995 in north Florida and south Georgia, *A. sagrei* individuals were usually present at northbound rest areas and welcome centers (Campbell and Hammontree 1995), whereas they were never present at facilities servicing only southbound traffic. If lizards were traveling mainly on potted landscaping vegetation from Florida, one would expect to find *A. sagrei* at both northbound and southbound facilities with equal frequency, but this is not the case. This evidence, along with that from Canaveral National Seashore and from spoil islands along the Intracoastal Waterway, give weight to the hypothesis that *A. sagrei* are being transported on recreational vehicles and boats in numbers suitable for the establishment of viable populations at remote sites.

Acknowledgments.—I thank the many hotel and restaurant owners, rest stop employees, campground hosts, city employees, the staff at Canaveral National Seashore and many others (the names being too numerous to mention here) who allowed me to prowl about their property searching for lizards.

BOOK REVIEWS

Pythons of the World. Vol. 1. Australia, by David G. Barker and Tracy M. Barker. 1994. Advanced Vivarium Systems, Inc., Lakeside, California, xviii + 171 pp. US $59.95 (cloth bound), US $39.95 (softcover).

BILL BRANCH
Port Elizabeth Museum, P.O. Box 13147, Humewood 6013 Eastern Cape, South Africa
e-mail: pemwrb@zoo.upe.ac.za

During the last five years there has been a massive explosion in the field of reptile and amphibian husbandry (herpetoculture), with the appearance of numerous glossy magazines, new dealers, expos, and exposés. The term herpetoculture makes me cringe and sounds like something out of a clinical pathology textbook and I must be frank and admit that I don't like the word, or some commercial aspects of its world. Nonetheless, I do like this book and it goes a long way to assuage my fears about the topic.

Announced as the first of a series by the authors on pythons of the world, this book covers the 21 python species and subspecies known from Australia. Printed on high-quality glossy paper throughout, the middle 80 pages are given over to a superb collection of color photographs. In another context, or if taken by lesser photographers, 197 color photographs of only 21 taxa would rightly be considered excessive. Certainly, if the rationale is simply to document a bit of variation and habitat, it is too much. However, this book is a labor of love and one of its aims is to generate similar feelings in the audience. In such a spirit, I found very few photographs I would have left out.

The individual taxa are described in detail in standardized format under the headings: Type locality, Other common names, Description, Sex determination, Size, Distribution, Habitat, Food, Breeding, Eggs, Hatchlings, and Comments. Each account also includes a line drawing of the head, a generalized distribution map, and tables for egg and hatchling measurements and a chronology of reproductive events. Five appendices give annotations for the figures, details of relative clutch weights, a map of Australia, position of internal organs in a diamond python, and a python reproduction questionnaire. The final five pages include a glossary and a comprehensive bibliography.

A minor failing is the lack of keys, or useful explanation of diagnostic features for identification of the different taxa. The almost draconian Australian regulations make legal acquisition of the continent's herpetofauna all but impossible. Therefore, many trade specimens derive second or third hand from successful breeding programs begun with specimens initially obtained illegally and often without provenance. Specimens need to be accurately identified if they are to be used in breeding programs designed to maintain, not contaminate, genetic purity.

A failing of many popular husbandry books is the superficial, and often antiquated science, particularly systematics. Boid systematics has seen more upheaval in recent years than most other squamate groups, and it is doubtful whether the dust has finally settled into bedrock foundation. The literature is often obscurely placed, and is usually caged in esoteric jargon. It is no easy task to keep on top of it, either in access or philosophy. It is, therefore, very satisfying to see how comprehensively and accurately the authors have covered this difficult field. In many species accounts the authors make informative comments on taxonomic controversies, in simple and lucid terms, and they are not over-awed

from giving their own, reasoned opinion (e.g., *Liasis fuscus*, p. 30, and *Morelia bredli*, pp. 44-45). They also make a pertinent comment on the valueless taxonomic importance of the increasing number of captive-bred intrageneric hybrids.

Elsewhere (p. 133), in their treatment of races in carpet pythons, the authors fully face the contentious nomenclatural 'anarchy' of Wells and Wellington (1984, 1985). It was probably an easier move for non-Australians, but still required strong stomachs. Morals count for nothing in nomenclatural priority, and the names proposed by Wells and Wellington, despite their often crass and plagiarized roots, still have to be used. In this particular case, however, one name is acceptable for other reasons; *Morelia spilota mcdowelli*, revived by the authors for the coastal carpet python, is named for a true, gentle giant of herpetology, Sam McDowell.

The authors stress their personal philosophy that efficient, concerned captive breeding programs (CBP) benefit wild populations by relieving exploitation on them, and their own results ably demonstrate that all python species are amenable to captive husbandry, albeit that the long-term captive maintenance of diamond pythons remains so elusive. However, rare and protected pythons command very high market prices, and therefore stimulate attention from the 'less-than-honest' fringe. During the last 30 years the legal export of Angolan dwarf pythons for a CBP has been allowed only twice, and involved only six specimens that went to South Africa (4) and Germany (2). Even then, some of the adults and progeny were supposed to remain the property of the Namibian authorities. Despite this, a large shipment of *Python anchietae* recently turned up in the United States, shipped via West Africa and ostensibly legally obtained in Angola (during a period when the country was gripped by a violent and dirty civil war). The Namibian authorities know that most, if not all, were smuggled from Namibia. This increased smuggling took place in the face of successful, and well publicized CBPs at several Texas zoos.

I have discussed elsewhere (Branch and Griffin, *in press*) how the very successes of high profile CBPs may stimulate illicit trade and attract the unwanted attention of dishonest collectors. Obviously, the zoos and curators initiating CBPs do so for genuine reasons, and are rigorous in ensuring they obey moral imperatives and import and export regulations. However, whether CBPs help conserve endangered species, or unintentionally stimulate excess illegal attention, remains an ethical dilemma. It will therefore be a genuine tragedy, and no small irony, if the very enthusiasm and expertise that this book displays, generates such a commercial demand that it threatens the very species that it so beautifully celebrates.

I have only two personal frustrations. The first is that I was only given the soft-cover edition—it is already suffering excessive use. Too many colleagues simply 'ogle' the superb photographs. The second is that it preempts a book I always wanted to write myself. Fortunately I never did, and the dream is now redundant thanks to the photographic, literary, and husbandry skills of Dave and Tracy Barker. I wish them well with the remaining volumes in the series.

CARL H. ERNST
Department of Biology, George Mason University
Fairfax, Virginia 22030, USA
e-mail: cernst@gmu.edu

This is the first volume of an intended two volume series covering the herpetology of Virginia. A second volume on amphibians is in preparation.

The slant of the book is, admirably, biodiversity and conservation of the 62 species of reptiles (23 turtles, 9 lizards, 30 snakes) known to occur within the boundaries of the Commonwealth of Virginia. The meat of the book is composed of accounts of each reptile species. These accounts include subsectional discussions covering systematics (current usage), description, morphology, coloration and pattern, sexual dimorphism, juveniles, confusing species, geographic variation (it is refreshing to see acknowledgement that two subspecies of the timber rattlesnake exist in the southeastern United States), etymology of scientific names, distribution, biology, miscellaneous remarks (often historical), and conservation and management of the species. The subsection covering the biology of the reptile is generally the longest in each account, and includes condensed comments on habitats, activity periods, prey and feeding behavior, predators, and reproduction with emphasis on data from Virginia. Data presented are generally well referenced. Although adequate, the various topical discussions presented in the biology subsection are somewhat shallow, and could have been greatly expanded. The descriptive portions of the species accounts are good, and those on juveniles are very helpful (juvenile descriptions are often neglected or inadequate in state herpetologies). The distribution discussion is brief, but maps showing both the species range in Virginia and the United States are included. Unvouchered records marked on the Map of Virginia are listed in the text. Here a problem arises, as some county records have been missed, and many records listed as unvouchered, particularly in northern Virginia, are represented by vouchered specimens in collections (D'Alessandro and Ernst 1995).

Other supporting chapters in the book include a brief introduction; materials and methods, explaining how original data were collected; history of reptile studies in Virginia; physiographic regions and climate of Virginia; natural habitats and reptile communities; biogeography, including the effects of human activities on reptile distribution patterns within the Commonwealth; conservation of Virginia's reptiles; venomous snakebite; and a checklist and comments on systematics. Separate keys are included for identifying turtles, lizards and snakes, and there are good black and white drawings of pertinent features referenced in these keys. Also included are short presentations on the characteristics of the Class Reptilia and all orders and families of reptiles living in Virginia. The last chapter in the book covers erroneous (5 species), problematic (3) and introduced (7) species. Included among the erroneous species is the American alligator, *Alligator mississippiensis*, whose northern limits along the East Coast are often mistakenly stated to be the Dismal Swamp in southeastern Virginia, when in reality the species does not naturally range north of the southern portions of Albemarle Sound, North Carolina. An adequate glossary explaining the biological terms used in the text and a Literature Cited section referencing all papers mentioned in the text are present. An index to scientific and common names ends the book, while a good Table of Contents begins it.

The book is well illustrated with 63 excellent color plates showing various reptilian habitats and some, but not all, of the 62 reptile species. Only 31 species are found among the color plates (11 turtles, 5 lizards, 15 snakes), although some species are included several times: the bog turtle, *Clemmys muhlenbergii* (2 plates); red-bellied turtle, *Pseudemys rubriventris* (2); slider, *Trachemys scripta* (6); stinkpot, *Sternotherus odoratus* (3); milk snake, *Lampropeltis triangulum* (3); northern water snake, *Nerodia sipedon* (2); copperhead, *Agkistrodon contortrix* (3); and timber rattlesnake, *Crotalus horridus* (4). Two maps are also given covering the counties and selected independent cities, and the physiographic provinces of Virginia. Eight tables addressing various topics are scattered throughout the book.

The book has a hard cover with an adequate binding and good quality paper. The print is large and easy to read. The dust jacket is colorful and attractive, showing three species and a cypress swamp habitat.

Although a few problems have been mentioned above, Dr. Mitchell is to be congratulated for a job well done. This book is recommended to anyone interested in the herpetology of the Middle Atlantic Region, and Virginia in particular. I look forward to the future volume covering Virginia's amphibians.

Guide to the Frogs of the Iquitos Region, Amazonian Peru, by Lily O. Rodríguez and William E. Duellman. 1994. Univ. Kansas Publications, Natural History Museum. Special Publication No. 22. 80 pages. US $19.95. ISBN 0-89338-047-4.

JAIME E. PÉFAUR
Ecología Animal, Facultad de Ciencias
Universidad de Los Andes, Mérida, Venezuela 5101

This guide to the anurans of an Amazonian region of Peru appears at a time when the subject of biodiversity seems to pervade all fields of biology. Amazonia is, by far, the place with the greatest biodiversity in the world, expressed at all organizational levels of organic matter, e.g., fungi, ferns, trees, butterflies, bats, and of course frogs. However, this region of South America is facing devastating destruction by deforestation, which reaches an annual rate of 0.4% in Peru to 1.2% in Venezuela—that is, in less than five decades there will be immense prairies instead of the luxurious forests of today.

Biologists attempting to record the biota of the Amazon face several difficulties, ranging from logistics to classification. Thus, I applaud the goals of University of Kansas Publications to initiate a series of guides to the plants and animals of the Iquitos Region. I am sure that this will be a most important contribution to the knowledge of Amazonian biota.

The *Guide* begins with biographical sketches of the authors and a preface. Eleven pages are dedicated to an Introduction, with statements about worldwide, South American, and Amazonian diversity of anurans, the biology of frogs, the vocalization of male frogs in an eco-ethological context, and the breeding behavior of Iquitos frogs. Information on how the guide should be used, scientific names, and anatomical, ecological, and ethological terminology (86 terms) complete this section of the book.

Sixty-seven pages make up the "Guide to the Frogs" chapter. Here 112 species are carefully described, with three paragraphs devoted to each taxon under the headings "identification," "similar species," and "natural history." The authors present diagnostic characters clearly. Working at my lab, I selected the cases of *Hyla punctata*, for its wide Amazonian distribution, and *Leptodactylus pentadactylus*, a very well known large frog but easily confused with other large *Leptodactylus*, to test Rodríguez and Duellman's diagnostic characters. I readily separated the target species from those of similar appearance.

The next section, "Selected References," is an annotated bibliography of nine references—including five by Duellman and two by Rodríguez. Two important references, of particular significance with respect to the topic of the *Guide* have been omitted: Duellman and Salas (1991) and Rodríguez et al. (1993).

A section of color plates finishes up the book. Of the 112 described species, only one, *Eleutherodactylus aaptus*, is not illustrated. Most pictures were taken by the junior author, and all show the principal traits of the frogs, although pictures of *Ceratophrys cornuta, Phyllomedusa vaillanti, Eleutherodactylus altoamazonicus*, and *Vanzolinius discodactylus* could be improved for the next edition. I know of no other guide to South American vertebrates (other than birds) that has so many color pictures of such excellent quality. To my knowledge, the only comparable publication could be *Frogs of Boracéia* (Heyer et al. 1990). However, their publication is aimed at herpetologists and could not be seen as a general guide, although it has been of great importance helping researchers at many South American universities in their studies. Unfortunately, the plates in Rodríguez and Duellman are not firmly bound—with the normal reading use of the book, plates 2 to 11 fell out of my copy.

The only map of the Iquitos region provided appears inside the back cover. This is a close-up of the Iquitos region of Peru. This book does not contain a general map of Peru, not even as an insert in the Iquitos map. Such a map, showing the boundaries of Iquitos, as a Departamento of Peru, would place the area in context for the general reader and provide an appropriate backdrop against which the anuran diversity of the region could be appreciated.

The Guide appears designed mainly for a non-technical audience. This is supported by the section on the construction of scientific names, a need for a layman, but not for someone with at least an elementary biology background; on the other hand, in the description of every species there is a section on tadpole morphology and natural history that is very complete and far too technical for non-specialists.

I anticipate that this guide will be successful. The time is right for its appearence; its presentation is appealing, the price is fair, the information is provided by authorities, and the need for it is great. Everyone traveling to the Peruvian Iquitos region should carry a copy of this small book to help them enjoy and appreciate the local frogs. Every herpetologist wishing to know or to work with Amazonian frog communities should have this guide to help confirm identifications.

DUELLMAN, W. E., AND A. W. SALAS. 1991. Annotated checklist of the amphibians of the Cuzco Amazonico, Peru. Occas. Pap. Mus. Nat. Hist. Univ. Kansas. No. 143:1–13.

HEYER, W. R., A. S. RAND, C. A. G. CRUZ, O. L. PEIXOTO, AND C. E. NELSON. 1990. Frogs of Boracéia. Arq. Zool. 31:231–410.

RODRÍGUEZ, L. O., J. H. CÓRDOVA, AND J. ICOCHEA. 1993. Lista Preliminar de los Anfibios del Peru. Publ. Mus. Hist. Nat. Univ. Nac. Mayor San Marcos (Ser. A), 45:1–22.

PUBLICATIONS RECEIVED

Australian Frogs (computer information disk), by Ross Sadlier and Martyn Robinson. Australian Museum, Sydney. 1996. AU $15.00 + AU $1.50 ($2.00) postage and handling (available from Mail Order Shop, Australian Museum, 6 College St., Sydney, NSW 2000, Australia—credit card orders accepted).

This is one of a series of information disks put out by the Australian Museum on a variety of topics in Australian natural history. The interactive program comes on a single 3.5" disk and after installation (about 5 minutes on a 486 machine) occupies approximately 3 MB. The program runs under Windows (3.1 or later) and requires a PC with at least a VGA screen set for 256 colors. In all about 70 pages of text and 40 color photographs are included. Information may be accessed under the major headings: frog diversity, disappearing frogs, lifecycle, frogfacts, habitat diversity, things to do, about this disc, and about the Australian Museum. A complete checklist of Australian frogs is included, but photos and text refer only to representative or particularly noteworthy taxa. Addresses for 23 herpetological associations and study groups in Australia are also provided, as are capsule summaries of the research interests of each of the scientific departments of the Australian Museum. There is an index and a search option, and both photos and text can easily be printed out. Although aimed at interested amateurs and the general public, this program serves as an excellent introductory short course on Australian amphibians, even for professionals who may not be familiar with the fauna.

Geographic Distributions of the Amphibians and Reptiles of Wisconsin, by Gary S. Casper. Milwaukee Public Museum, Wisconsin. 1996. Softcover. 87 pp. ISBN 0-89326-200-5. US $10.00 + $3.00 shipping and handling (available from Milwaukee Public Museum, 800 W. Wells St., Milwaukee, Wisconsin 53233, USA).

This short book is an interim report of the Wisconsin Herpetological Atlas Project and presents maps depicting species distribution, by county, in Wisconsin. New county records since the publication of Vogt's *Natural History of Amphibians and Reptiles in Wisconsin* (1981) are mapped and the associated publications and voucher specimens are cited. In all 461 new county records are presented for the 55 species of amphibians and reptiles inhabiting the state. Each species map is accompanied by a short paragraph with notes about distribution and/or status of the associated taxon.

New Zealand Frogs and Reptiles, by Brian Gill and Tony Whitaker. David Bateman, Ltd., Auckland. 1996. Softcover. 112 pp. ISBN 1-86953-264-3. NZ $24.95 (approx. US $17.50).

This is an updated version of Gill's 1986 book, *Collins Handguide to the Frogs and Reptiles of New Zealand*. Species accounts are provided for 59 species (plus six recently extinct forms), up from the 43 forms covered a decade ago. Accounts are brief (description, size, distribution, habitat, habits, and notes) and are illustrated by color photos. Keys are provided as is a short list of suggested readings. Although too superficial to provide much introduction to the biology of the New Zealand herpetofauna, the book provides a convenient introduction to the species and is the only popular work to incorporate all of the country's many new and resurrected species (plus one genus).

Okoboji Wetlands: A Lesson in Natural History, by Michael J. Lannoo. University of Iowa Press, Iowa City, Iowa. 1996. 156 pp. Cloth (US $29.95) or softcover ($14.95). ISBN 0-87745-532-5 (cloth) or 0-87745-533-3 (softcover).

Lake Okoboji in northwest Iowa is a region of wetlands renowned for its rich animal life. Lannoo combines historical field records and other reports with more recent work to track changes in the composition and abundance of the fauna. Extensive natural history information on frogs and salamanders is presented (in addition to material on birds, mammals, and fish). A thorough discussion of larval eastern tiger salamanders (*Ambystoma t. tigrinum*) includes diagrams of normal and cannibal morph skulls and dentition. Several brief essays provide fascinating details of commerical harvesting of leopard frogs (*Rana pipiens*) at the turn of the century; one source estimates the take by just three men at ten million frogs from Okoboji in the winter of 1905-06. Lannoo makes the case for conserving these wetlands and their inhabitants and offers specific management strategies for doing so.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986–1996, *et seq*. Privately published by and available from the author (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024, USA). Individual accounts available separately. Cost: US $0.10/page + postage and handling.

The most recent installment (number 16) in this series is *Phrynosoma cornutum*, the Texas horned lizard. This account totals 52 pages in addition to a detailed range map. Of particular interest to students of *Phrynosoma* is Axtell's support for a change in the type locality for *P. cornutum*, and his delimitation of the natural range of this species in east Texas, an area where extensive introductions have occurred.

ERRATA

In the Natural History Note by William E. Magnusson that appeared in the March 1996 issue of HR (27:21), a typesetting error resulted in the incorrect spelling of the lizard genus *Neusticurus*.

Also, we inadvertently left out complete locality coordinates for the *Hemidactylus turcicus* range extension reported by Proudfoot and McCoid in the June 1996 issue (27:87). Locality data should have read: USA: TEXAS: Kenedy Co: 26°46'20"N, 97°42'20"W.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Techniques, Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at 303 West 39th Street, Hays, Kansas 67601-1518, USA. Application to mail at 2nd Class Postage rates is pending at Hays, Kansas with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, P.O. Box 626, Hays, Kansas 67601-0626. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Karen Toepfer, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 600		$300
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 600	$150

For back orders only: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA (fax 314-977-3658). E-mail: aldridge@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1996 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. All members receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Karen L. Toepfer, SSAR Treasurer, P.O. Box 626, Hays, Kansas 67601–0626, USA. Telephone: (913) 623-4258; Fax: (913) 625-8890; e-mail: fmkt@fhsuvm.fhsu.edu.

Future Annual Meetings

1996 — University of Kansas, Lawrence, Kansas, USA, 24–29 July (Linda Trueb, Chair).
1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July (Theodore Pietsch, Chair).
1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).

SSAR BUSINESS

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 1997 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include in-situ behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.

3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on an herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president.

5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.

6. INTERNATIONAL. Proposals may address needs in any of the above five categories, but applicants must be from countries where herpetological research has historically been underfunded, and where alternative sources of financial support are scarce or nonexistent

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR with the exception of those applying for support of regional herpetological society

About Our Cover: *Hynobius retardatus*

Although widely distributed in eastern Asia, salamanders of the genus *Hynobius* (family Hynobiidae) are most highly differentiated in Japan. Stejneger (1907. Bull. U.S. Nat. Mus. 58:1–577) listed only five species of this genus in the territory now belonging to Japan, but the number has increased to about 16 (Matsui 1996. Natural History of the Amphibia. Univ. Tokyo Press), and others await description. *Hynobius retardatus*, the Ezo salamander, is the northernmost member of the genus, and is endemic to Hokkaido, the northern main island of Japan. Adults are about 60–85 mm SVL, with individuals from higher elevations tending to be larger. The slender tail is slightly longer than the body.

Ezo salamanders uniquely possess a shallow vomerine tooth series and a small number of chromosomes ($2n = 40$), in contrast to deeper U- or V-shaped vomerine tooth series and a larger number of diploid chromosomes ($2n = 56$ or 58) in other Japanese *Hynobius* (Matsui et al. 1992. Herpetologica 48:408–416). Because of these unique characteristics, among others, this species has been placed in its own genus, *Satobius*, by some authors (Adler and Zhao 1990. Asiatic Herpetol. Res. 3:37–45).

Ezo salamanders breed in spring, from early April to late May; in higher localities, the breeding season begins as late as early July. Many individuals are found aggregating in marshes and ponds at this time. Most of these are males waiting for the arrival of females. When a female arrives and begins to spawn (depositing a pair of egg sacs on submerged dead leaves), males attempt to pull eggs from her cloaca as quickly as possible. The males are preoccupied with egg sacs and pay little attention to the female. Males embrace the egg sacs until they have finished releasing sperm. The large number of males actively seeking to fertilize a single female's spawn results in a spectacular competition. Each egg sac contains 35–50 eggs, and larvae hatch within 30–40 days. Some larvae metamorphose 40–50 days after hatching, but others take considerably longer—up to 1–2 years post-hatching. A neotenic population of *H. retardatus* was reported from Lake Kuttarush over 70 years ago (Sasaki 1924. J. Coll. Agricult. Hokkaido Imp. Univ. 15:1–36), but all subsequent searches of this lake have failed to confirm this finding.

The salamander on the cover is an adult male *Hynobius retardatus*, photographed in a tank near the breeding site at Teshikaga. It was photographed with a Mamiya RB67 camera, using a standard 90 mm lens and a flash unit. The photographer is **Norio Maeda**, co-author with **Masafumi Matsui** of *Frogs and Toads of Japan* (1989. Bun-ichi Sogo Shuppan, Tokyo). Maeda's dream was to publish a book of art, rather than of science, using photographs of Japanese frogs that he had been accumulating for more than ten years. Few publishers, however, agreed with his plan, partly because books of a similar genre were already available. After discussions with Maeda, Matsui agreed to prepare taxonomic text for some of Maeda's photographs and consulted with a publisher about the prospects for a book whose focus was mainly taxonomic. New photographs were systematically accumulated within a short period, and the book was completed, albeit in a fairly different form from what Maeda first intended. Maeda's dream, however, is going to be partly realized with the publication of a photo book of frogs and toads of the world; he is now very busy in its preparation. Maeda is also a co-author of a CD book on songs of Japanese birds and frogs, and his photographs are popular inclusions in many books that picture Japanese amphibians and reptiles.

This cover commemorates the re-issuance this month by SSAR and the Herpetological Society of Japan of Leonhard Stejneger's long-out-of-print, classic monograph *Herpetology of Japan and Adjacent Territory*. Matsui provides a new introduction to the reprint, noting that Stejneger's 156 species today represent 180 taxa.

Separation and imaging of Maeda's photograph is the work of **Jim Bridges** of Herpeto Inc., Hollywood, Florida, USA.

projects. Membership dues must be paid (to SSAR Treasurer) no later than 31 December 1996 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project. (B) METHODS of carrying out the project. (C) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). (D) BRIEF RESUMÉ of the applicant or project coordinator. (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages excluding resumé and budget.

Applicants must designate to which of the five categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than 31 DECEMBER 1996 to be considered. Please include office and home phone numbers, as well as fax number and e-mail address if available. It is often necessary to contact applicants quickly. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1997. Successful applicants will be expected to submit a written report of the results of this support within a reasonable amount of time after the project year is completed. They are also encouraged to submit the results of research projects for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Julian C. Lee, Chair, SSAR Grants-in-Herpetology, Department of Biology, P.O. Box 249118, University of Miami, Coral Gables, Florida 33124, USA. Tel. (305) 284-6420; fax (305) 284-3039; e-mail: jlee@umiami.ir.miami.edu.*

Applicants must include a statement indicating that they "will comply with all applicable permit regulations, and adhere to all appropriate animal care guidelines in the course of conducting funded projects."

Grants-in-Herpetology Donors

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible (for U.S. residents) contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

Annual Report (1996) Grants-in-Herpetology Committee

Five awards of $500 each in four categories were made this year, as follows:

Conservation.—**Jeff Demuth**, Southeastern Louisiana University. Project title: "A test of the effects of incubation temperature on sex determination and peformance of hatchling gopher tortoises (*Gopherus polyphemus*)."

Laboratory Research.—**Erik W. A. Gergus**, Arizona State University. Project title: "Effects of post-Pleistocene xerification on the population genetic structure of the tree frogs *Hyla regilla* and *H. cadaverina* in Baja California, México."

Laboratory Research.—**Wendy H. Wente**, Indiana University. Project title: "Sensory basis of background color matching in a color-polymorphic treefrog: implications for the evolution of assortive mating within an interbreeding population."

Field Research.—**S. Rebecca Yeomans**, University of Georgia. Project title: "Tests of the parental investment in care hypothesis in chelonians."

Travel.—**Todd Campbell**, University of Tennessee. Project title: "An experimental analysis of the interaction between a native anole (*Anolis carolinensis*) and an introduced anole (*A. sagrei*) using dredge spoil islands."

1996 Grants-in-Herpetology Committee: Kelly Zamudio, University of Washington; Dr. Barbara Savitzky, Christopher Newport University; Dr. Randy Jennings, Western New Mexico University; Dr. Carole L. Hom, University of California, Davis; Janice Perry, Arizona-Sonora Desert Museum; Dr. Julian C. Lee, University of Miami (chair).

Third World Congress of Herpetology Travel Awards and Donations

The American Society of Ichthyologists, the Herpetologists' League, and the Society for the Study of Amphibians have applied to the National Science Foundation for a joint Conference Travel Grant. The funds are to assist graduate students and young professional herpetologists to travel to the Third World Congress of Herpetology in Prague, Czech Republic 2–10 August 1997. We are requesting 21 travel awards of $1428 each. NSF's decision on funding will not be known until after 1 January 1997. We are therefore soliciting proposals at this time to be submitted BEFORE 1 January 1997. Awards will be restricted to graduate students, post-doctoral fellows, and young professionals (35 years or less in age) who are members of one of the above herpetological societies and who are US citizens (necessary for NSF awards).

Those applying should submit: 1) a statement of their present academic or employment status (e.g., Graduate Student at the University of Illinois; Assistant Professor of Zoology at the University of Tennessee); 2) an abstract of a talk or poster that they plan to present at the Congress; 3) a statement of their need of assistance, from their supervisor or department head; 4) a letter confirming participation in the program or other indication of inclusion, if possible. Applications will be judged by a committee of three (one representative from each society). Send applications to World Congress Travel Grant, c/o Margaret M. Stewart, President of ASIH, Department of Biological Sciences, State University of New York at Albany, Albany, New York 12222, USA. Women and minorities are urged to apply.

At present, any travel awards are contingent on funding by NSF of the proposed travel grant. However, organizations and individuals are encouraged to send additional donations for this purpose. Checks should be made out to ASIH, earmarked for World Congress Travel Awards, and sent to the above address. The selection committee will award all funds received.

Information about the Congress can be found on their World Wide Web page (www.gli.cas.cz) or their mail server (wchsource@gli.cas.cz; see March 1996 *Herpetological Review*).

NEWSNOTES

Collins Honored as Kansas Wildlife Author Laureate

A proclamation passed by the Kansas state legislature and signed April 10, 1996 by the governor installed long-time SSAR member and editor Joseph T. Collins as Kansas Wildlife Author Laureate, the first person to hold this position in Kansas. This honor was in recognition of Collins' efforts to educate the people of Kansas about their plant and animal heritage through publication of numerous books and articles. SSAR congratulates Joe on this unique achievement.

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due on 15 October 1996, with notification by 1 December 1996. Grantees are expected to complete their Academy visit by 15 September 1997. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

A Call for a New International Congress of Zoology

We are seeking responses concerning the feasibility of a New International Congress of Zoology, possibly to be convened in Athens, during 1999 or 2000. Seventy years after the First Zoological Congress in Paris in 1889, the XVIth Congress in Washington recommended the discontinuation of the congresses, because the feeling that zoology has split into too many unrelated fields.This was criticized by the last (XVIIth) Congress in Monte Carlo in 1972, but to no avail. The alternatives proposed (like ICSEB) did not live up to the expectations.

One of the most painful results of the discontinuation of the congresses was the general depreciation of zoology in the academic world as such, and the frequent use of dissimulating its name under a plethora of more fashionable euphemisms. The widely circulated "Systematics Agenda 2000" emphasizes our present incapacity to scientifically describe a zoological biodiversity which suddenly appears to be one order of magnitude larger than envisaged back in the 1970's. A critically depleted and weakened community of zoological systematists cannot live up to the task of investigating and protecting the heritage of the animal world.

Thirty years after the last congress, zoology at the end of this century is different. There are many developments which cut across the narrow specialities and which have to be appreciated by an international forum. Confined to the pages of specialized journals, these important developments often did not reach the attention of peers in other zoological specialities. It would be important to inform our colleagues about the newly discovered phyla and classes, the new concepts of vertebrate evolution, the biology of clonal animals, present views on the Protozoa, etc. A sample of subjects of wider implications are sociobiology, cladistics, molecular taxonomy, modern epigenetic embryology, the new vision on the Cambrian revolution, neocatastrophism, vicariance zoogeography, cryopreservation, and cloning. This is indeed a different zoology from that which ended with a whimper in Monte Carlo.

We are ready to try to bring forward again the rich and unifying aspects of zoology and to reassert its general global, human, and philosophical role. For this we need the support of the zoological diaspora. Please communicate your opinion to the correspondents below, and more important, suggestions and personal commitments to participate in the organization of our next congress.

Dr. F. D. Por, Hebrew University of Jerusalem, Department of Evolution, Systematics and Ecology, POB 91904, Jerusalem, Israel. E-mail: POR@VMS.HUJI.AC.ILI

Dr. Rosa M. Polymeni, Department of Biology, Section of Zoology, University of Athens, POB 15784, Athens, Greece. E-mail: rpolime@atlas.uoa.gr.

MEETINGS

Meetings Calendar

14–22 October 1996—4th Latin American Congress of Herpetology, University of Chile, Santiago de Chile, Chile. Contact: Dr. Alberto Veloso, Depto. de Ciencias Ecologicas, Facultad de Ciencias, Universidad de Chile, Casilla 653, Santiago, Chile; e-mail: veloso@abello.dic.uchile. For registration within the U.S. and Canada, please contact: Rafael de Sá, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA; e-mail: desa@urvax.urich.edu.

27–30 November 1996—IV Reunion Nacional de Herpetologia, Universidad Autónoma del Estado de Morelos, Cuernavaca, Morelos, México. Contact: María Guadalupe Bustos Zagal, Lab. de Herpetología, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Morelos, Av. Universidad 1001, Chamilpa 62210, Cuernavaca, Morelos, México. Tel. (73) 29 70 29; fax (73) 29 70 56; e-mail: bustos@cib.uaem.mx.

12–13 December 1996—XII Reunion de Comunicaciones Herpetologicas and Annual Meeting of the Asociacion Herpetologica Argentina, Universidad Nacional de Rio Cuarto, Cordoba, Argentina. Contact: Liliana Aun, Comision Organizadora XII RCH, Universidad Nacional de Rio Cuarto, Estafeta Postal 9, 5800 — Rio Cuarto, Argentina. E-mail: rmartori@unrccc.edu.ar.

13–18 January 1997—IUCN Northern Indian Ocean Marine Turtle Workshop, Bhubaneswar, Orissa, India. *Refer to meeting announcement below for details.*

2–10 August 1997—Third World Congress of Herpetology, Prague, Czech Republic. Contact: Zbynek Rocek, Congress Director, Department of Paleontology, Geological Institute, Academy of Sciences, Rozvojová 135, 165 00 Praha 6 – Suchdol, Czech Republic. Tel. (++42-2) 24311421; Fax (++42-2) 24311578; e-mail: rocek@gli.cas.cz. *Refer to meeting announcement in* Herpetological Review *27(1):4–5, March 1996 for details.*

IUCN Northern Indian Ocean Marine Turtle Workshop

A regional workshop, under the auspices of the IUCN/SSC Marine Turtle Specialist Group and sponsored by the U.S. National Marine Fisheries Service and the Convention on Migratory Species, will be held in Bhubaneswar, Orissa, India, from 13–18 January 1997. The objectives of this workshop are to develop a regional conservation strategy for marine turtles, improve networking and communication among marine turtle researchers and managers, and train researchers and managers. Country representatives from the region will present current information regarding the status of sea turtle populations within the region. The workshop is open to anyone who wishes to attend. For more information contact: *Dr. Priyambada Mohanty-Hejmadi, Vice Chancellor, Sambalpur University, JYOTIVIHAR, Sambalpur 768019, Orissa, India (tel. 91-663-430158; fax 91-674-481418) or Dr. Pamela Plotkin, Drexel University, Department of Bioscience & Biotechnology, 32nd and Chestnut Streets, Philadelphia, Pennsylvania 19104, USA (tel. 215-895-1436; fax 215-895-1273; e-mail: Plotkipt@post.drexel.edu).*

1st Annual Meeting of the Working Group on Amphibian and Reptile Conservation in Canada and 6th Annual Meeting of the IUCN/SSC Task Force on Declining Amphibian Populations in Canada (DAPCAN)

These meetings will be held at the University of Calgary, Calgary, Alberta, 5–7 October 1996. This year's program will include a symposium on "The Conservation of Reptile Populations in Canada" and a workshop on "Herpetological Atlasing." All those who received the last issue of *The Boreal Dip Net* newsletter will already be on our mailing list and can expect to receive an invitation to these meetings. If you are not already on our mailing list and would like to receive the Call for Papers and Registration Forms please contact: *Stan Orchard, National Co-ordinator, 1745 Bank Street, Victoria, British Columbia, CANADA, V8R 4V7. Telephone/Fax: 604-595-7556. E-mail: sorchard@islandnet.com. Messages can also be left at the Royal British Columbia Museum at 604-387-3649.*

North American Amphibian Monitoring Program 3rd Annual Meeting

A meeting to present, evaluate, and discuss amphibian monitoring techniques for North America.

Location: The meeting site will be Planet-wide, located on the Internet via the World Wide Web at the following mirrored locations:

National Biological Service - Inventory and Monitoring http://www.im.nbs.gov/naamp3/naamp3.html
Environmental Protection Agency - New England http://www.
National Biological Service - Northern Prairie Science Center http://www.npsc.nbs.gov/naamp3/naamp3.html

Date: 14 November 1996

Registration Fee: None! Housing Fee: None!

Sessions: Papers will be presented in electronic format (HTML documents), complete with graphics, tables, and E-mail links to the authors. Participants can query authors directly using simple electronic forms. These electronic forms send E-mail back to the author. The author answers the question and both the original and the answer are posted back at the bottom of the paper within a day of the author's reply.

Meeting participants can watch the meeting evolve over a period of several weeks as questions and answers are posted. The meeting will remain active at all 3 sites for a period of 3 months and will remain indefinitely at the NBS Inventory and Monitoring site as an archive of the meeting. The meeting will emphasize the following:

New Techniques – Descriptions of potentially useful new monitoring techniques.

Evaluations and Validations of Proposed Techniques – Following NAAMP II, a number of techniques were proposed as potentially useful in developing region-wide monitoring programs. Papers will focus on the statistical validation and evaluation of amphibian monitoring techniques and discuss their relevance to proposed regional monitoring networks.

International Models – Summaries and evaluations of amphibian monitoring protocols and programs from outside of North America.

Reports on Calling Surveys – Progress reports from state and provincial coordinators on the status and experience of creating a regional calling surveys network.

Forum on the NAAMP Process – Online (NOT real time) discussions on the health and direction of AMP will be launched through a series of essays.

Field Trips: Hot links to Participating Agency Web Sites!

Further information may be obtained by visiting the AMP Web site: http://www.im.nbs.gov (click on amphibians) or contact: *Sam Droege, National Biological Service, Inventory and Monitoring Section, Laurel, Maryland 20708-4038, USA. Tel. 301-497-5849; fax: 301-497-5784; e-mail: frog@nbs.gov.*

OBITUARY

Robert Edward Gordon (1925–1996)

KRAIG ADLER
Cornell University, Division of Biological Sciences
Seeley G. Mudd Hall, Ithaca, New York 14853, USA
e-mail: kka4@cornell.edu

Robert E. Gordon, who served as President of the Society for the Study of Amphibians and Reptiles in 1971, died of cardiac arrest in La Grange, Georgia, on June 2nd. He was 70 years old.

Bob served SSAR in a number of important roles over many years. In 1967, the year in which the society changed its name from The Ohio Herpetological Society to SSAR, a symposium was held at the tenth anniversary meeting in Columbus, entitled "The Biology of Salamanders," which Bob organized and moderated with his usual skill and wit. He chaired the committee that rewrote the society's Constitution in 1970, a brilliant document which, once a few key points were established, in fact says very little more—the entire Constitution is only four pages in length—so as not to constrain innovation. During his year as president of SSAR, he completely overhauled and regularized the committee system and was intimately involved in the ongoing discussions with the Herpetologists' League concerning possible merger with SSAR.

His formal research career began at the University of Georgia, where, in 1950, he completed a master's degree under the celebrated ecologist Eugene P. Odum. His thesis concerned the life history and ecology of the then little-known green salamander (*Aneides aeneus*), research that was conducted in western North Carolina at Highlands Biological Station. Bob's long association with Highlands began in 1948 when he was an undergraduate at Emory University. The thesis was published in 1952, in the *American Midland Naturalist*, and constitutes Bob's most important published work, for his unusual talents for university administration were soon to be recognized. His doctoral work was conducted under the chairmanship of Fred R. Cagle at Tulane University, whose active laboratory then included a number of budding herpetologists pursuing master's or doctoral degrees: Paul K. Anderson, Don R. Boyer, Allan H. Chaney, Richard Etheridge, Richard M. Johnson, Howard K. Suzuki, Donald W. Tinkle, and Robert G. Webb, plus Ernest A. Liner and J. Whitfield Gibbons who were informally associated with the group. Bob's thesis, a detailed study of the demography of the green anole (*Anolis carolinensis*) was, unfortunately, never published, but it is still frequently cited. He received his Ph.D. in 1956. After a short stint as an assistant professor at Northeastern Louisiana State University, Bob joined the biology faculty at the University of Notre Dame in 1958, where he spent the rest of his professional career. Bob's research publications (1949–1968) dealt with the life histories and ecology of plethodontid and ambystomatid salamanders, the behavioral ecology of the rainbow snake, and homing behavior of salamanders.

At Notre Dame, Bob quickly ascended the ranks. He became Head of the Department of Biology in 1964 at the age of 39, Associate Dean of Science three years later, and finally, from 1971 until the year before his retirement from the faculty in 1990, was Vice President for Advanced Study (combining the roles of dean of the graduate school and head of all sponsored research on campus). Although he had many opportunities for advancement elsewhere, Bob was totally devoted to Notre Dame, despite the fact that all posts higher than his were (and still are) held by priests of the Congregation of the Holy Cross. Those were heady days at Notre Dame, under the 35-year-long presidency of Theodore M. Hesburgh, who was widely regarded as among the most enlightened and inspirational university leaders of this century. Bob was one of the most active and trusted members of the Hesburgh Administration, and on his retirement Notre Dame paid tribute to him with an honorary LL.D. degree, an honor almost never bestowed on the university's own faculty. Despite his administrative duties, Bob taught courses and even supervised several graduate students, among them Ronald Gratz, Julian R. Harrison, James A. MacMahon, David H. Snyder, Nicholas J. Sullivan, and J. Kerwin Werner.

In addition to his SSAR activities, Bob served numerous other organizations. He was President of the American Institute of Biological Sciences in 1976, President of the Board of Trustees of *Biological Abstracts* in 1978, and in 1989 was Chairman of the Board of Directors of the Council of Graduate Schools. In many respects he followed the interests of his mentor, Fred Cagle, by going into administration and in having a deep interest in scientific communication, documentation, and editing. He was Editor-in-Chief of the *American Midland Naturalist* (1958–1964) which is published by Notre Dame, Executive Secretary of the Council of Biology Editors beginning in 1963 (he received their Medal for Excellence in 1972), and served for a long time on both the Science Information Council of the National Science Foundation and its counterpart, the Council on Biological Science Information which advises the National Academy of Sciences.

If there are two kinds of people—squirters and sponges—as Bob often remarked, then he was a jet spray. Bob Gordon was the archetypal "Type A" personality: outgoing, extremely hard-working, involved in many activities simultaneously, and highly self-motivated. Although born in New York City (June 20, 1925), he moved to Georgia at an early age and developed the most wonderful Southern drawl, with a cadence and musical quality to it that was charming and sometimes even mesmerizing. As a faculty colleague at Notre Dame during the late 60s and early 70s, I, too, became enthralled by the Gordon charisma and only once, I think, could bring myself to say "no" to him: when he wanted me to request on my NSF grant one of those surplus U.S. Army amphibious vehicles—the ones often called "ducks"—for him to go surfing over land and water at the Notre Dame Biological Station, which he had developed in northern Wisconsin.

He was the consummate raconteur and an incredibly effective leader who could defuse the most tense situation more deftly than anyone I know. He had a contagious enthusiasm for science—his interests were broad, including botany and geology, but focused on ecology, behavior, and biogeography—that he carried into retirement in Georgia on a 6-acre plot of dry uplands pine woodlands. Almost every letter would bring news of his latest observations, with student-like exuberance, on the abundant local lizards, including his beloved anoles, or some rare interloper like a scarlet kingsnake. He had long had an interest in amphibians and reptiles on stamps and wrote a regular column on the subject for *Biophilately*. In 1977, he co-authored a booklet on herp and fish stamps, and in retirement he had been actively working on a comprehensive guide to the herp stamps of the world.

Bob Gordon is survived by his wife of 48 years, Catherine (Buddy to all their many friends), and two daughters, Claire and Martha Lee, and their families. His legacy to Notre Dame, to biological science in America, and to herpetology is great. We will miss him very much.

INSTITUTIONAL PROFILE

Herpetology at the Carnegie Museum of Natural History

ELLEN J. CENSKY
Section of Amphibians and Reptiles, Carnegie Museum of Natural History
4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213, USA
e-mail: censkye@clpgh.org

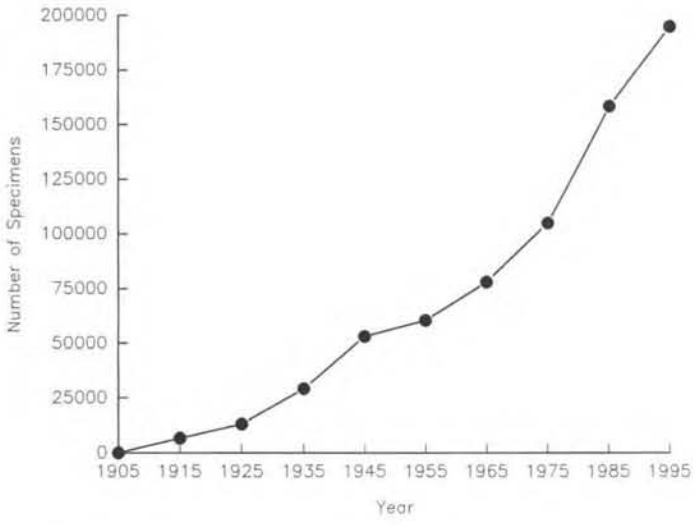
On June 1, 1996, the Section of Amphibians and Reptiles, Carnegie Museum of Natural History celebrated its 100th anniversary. In those first one hundred years the collection has grown to a size of over 195,000 specimens. Judged on the criteria of size and diversity of collection, and number of type specimens the collection ranks among the ten most important in the United States.

History.—During the first three decades the Section was staffed by part-time volunteer curators. While Section collection and research activity was sporadic, the museum did purchase significant collections from various parts of the world including Brazil, Bolivia, and the Bahamas. In addition, the museum mounted its own expedition to the Isle of Pines, Cuba in the early 1900's. The first herpetologist employed full-time by the museum was M. Graham Netting, who started in 1926 and continued as Curator-in-charge until 1955. Netting's interest in his early years focused on systematics and distribution of Neotropical amphibians and reptiles, and he made numerous collecting trips to the Caribbean and northern South America. Later his attention shifted to the Appalachian region, and these collections became the nucleus of our large eastern United States holdings.

After 1950, Netting became increasingly involved in museum administration, and was replaced by Grace L. Orton, who had joined the staff in 1945. Orton resigned in 1950 to be replaced the following year by Neil Richmond. Richmond's first activity was to complete a survey of Pennsylvania amphibians and reptiles, a project which Netting had initiated in the 1930's. He later turned his attention to the systematics of the blindsnake family Typhlopidae, and participated in four expeditions to the Bahamas. Richmond left the Section in 1974.

Clarence (Jack) McCoy joined the Section in 1964. His research interest in the reptiles of Central and South America led to a series of expeditions to those areas (1964–1988). Building on the base of the Neotropical collections established under Netting's tenure, the Latin American resources of the Section continued to grow. While McCoy continued to work in Latin America throughout his career, his emphasis switched in 1974 to systematics and ecology of turtles. He built one of the largest collections of freshwater turtles in the world. C. J. McCoy passed away in July 1993.

Ellen Censky joined the staff of the Section in 1979 as Collection Manager. Shortly after receiving her Ph.D. in 1994, she was promoted to Assistant Curator-in-charge. Her geographic area of research has been the Caribbean and central South America, and her research interests lie in behavioral ecology of lizards, Caribbean zoogeography, and systematics of *Ameiva*.



The newest member of the Section is John J. Wiens, who joined the staff as Assistant Curator in 1995. Wiens received his Ph.D. from the University of Texas at Austin in 1995. His research interests are the systematics of reptiles and amphibians, phylogenetic methodology, and morphological evolution.

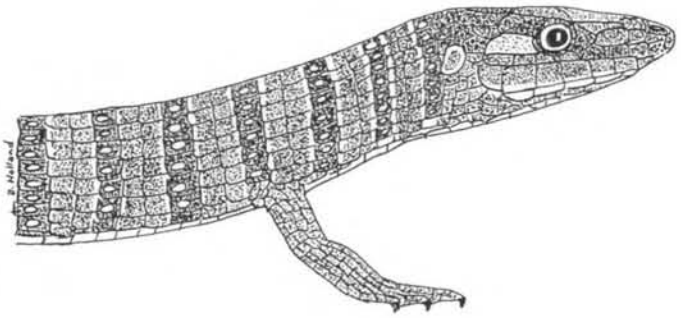
In addition to the two full-time curators, the Section currently has a split-time Preparator/Collection Manager position (Stephen P. Rogers) and a part-time Curatorial Assistant (Bonnie Isaac).

Collections.— The area best represented in the collection is the United States with 75% of the collection of U.S. origin. The local area from which we have the most complete collection is the Appalachians, reflecting 100 years of collecting and acquisition. These collections include recent large donations of Virginia amphibians and reptiles from Joseph Mitchell and Christopher Pague, salamanders from Barry Valentine, and eastern U.S. amphibians from James Fowler. Of course, the Pennsylvania collection is the most extensive in existence.

In addition to the U.S. collections, we have extensive collections from various other parts of the world, including South America, the Caribbean, Africa, and Asia. The earliest South American collections include the Haseman Brazilian Expedition (1907–1910), Colombian specimens from H. H. Smith, collections from the museum expedition to Venezuela (1929–1930), and Bolivian specimens purchased between 1913–1922. In more recent years, emphasis has shifted to southern South America (Chile, Argentina, Paraguay, Uruguay), and Central America (México,

Collection Growth at Carnegie Museum of Natural History, Section of Amphibians and Reptiles

Belize, Guatemala). The extensive Caribbean collection was established with the Worthington Bahamian collection (1909) and the museum's expedition to the Isle of Pines (1912). It continued to grow with six expeditions to the Bahamas (1942–1976), Coleman J. Goin's gift of Jamaican frogs, extensive donations (including many types) by Albert Schwartz, and recent research by Censky.



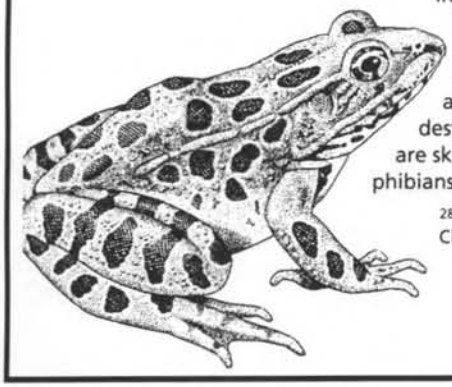
The collection from Spain, assembled and donated by Stephen D. Busack (Research Associate) is the largest Spanish collection in the United States and constitutes our largest European holdings. The African continent is well represented with both historical and recent collections. The largest collections (>500 specimens in each) are from Cameroon, South Africa, Namibia, Benin, Nigeria, and Morocco. There are smaller collections from most other African countries.

Our Philippine collection was founded early in the history of the museum with the purchase of part of the E. H. Taylor Collection which was rich in type material. More recent acquisitions from Luzon and Marinduque (Hahn Collection) have added to the strength of the Philippine collection. The India collection is more recent in origin. During the past 15 years, Research Associate Carl Gans (representing CMNH) has been conducting a joint herpetological survey with the National Museum of Natural History, New Delhi, which has generated a large collection of Indian amphibians and reptiles. Gans also has recently donated a large collection of skeletons to the Section.

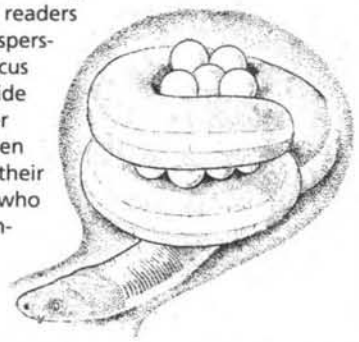
The turtle collection is unique in its potential as a systematic resource. It consists of over 26,000 specimens, including more than 3500 skeletons and a long series of hatchlings incubated at known temperatures. Collections from Richard Vogt, Edward Moll, and Michael Ewert form the nucleus of the turtle collection. The type collection in the Section consists of 2236 specimens in 440 taxa.

The section's library, recently named *The C.J. McCoy Memorial Library*, was established in 1914 by the purchase of the reprint collection of Albert C. L. G. Günther, late keeper of Zoology in the British Museum (Natural History). It is rich in 19th century European literature, and contains over 900 bound volumes including all major and many minor herpetological journals. It also contains over 23,000 reprints (all computerized).

The collection, which now consists of over 195,000 specimens, was computerized in 1979. A taxon listing, including the number of specimens of each species housed at Carnegie Museum of Natural History, can be obtained from the Herpetological Combined Museum Listings and can be accessed through the California Academy Gopher at cas.calacademy.org. To receive further information about the collections, please contact Ellen J. Censky (e-mail: censkye@clpgh.org) or John J. Wiens (e-mail: wiensj@clpgh.org).



"An excellent, informative book full of wonders and delights."
—*The Times Higher Education Supplement*



A Natural History of Amphibians

Robert C. Stebbins and Nathan W. Cohen

This is a book for all readers who want to learn about amphibians, the animal group that includes frogs, toads, salamanders, and caecilians. It draws on many years of classroom teaching, laboratory experience, and field observation by the authors. Robert Stebbins and Nathan Cohen lead readers on a fascinating odyssey as they explore some of nature's most interesting creatures, interspersing their own observations throughout the book. The authors focus our attention on the "natural history" of amphibians worldwide and emphasize their interactions with their environments over time: where they live; how they reproduce; how they have been affected by evolutionary processes; what factors will determine their destinies over time. Through the experienced eyes of the authors, who are skilled observers, we come to see and understand the place of amphibians in the natural world around us.

CURRENT RESEARCH

The purpose of **Current Research** is to present basic summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA; e-mail: herpbooks@sisna.com. Comments and suggestions are also welcome.

The current contents of several herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are being listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Mertensiella

The Deutschen Gesellschaft für Herpetologie und Terrarienkunde e.V. has published two more volumes of *Mertensiella*. The first of these consists of a single paper on Nile monitors in Gambia. The second volume contains eleven papers discussing the ecology and conservation of *Hyla arborea*.

LENZ, S. 1995. Zur Biologie und Ökologie des Nilwarans, *Varanus niloticus* (Linnaeus 1766) in Gambia, Westafrica. Mertensiella (5):1–256.

GEIGER, A., ed. 1996. Der Laubfrosch *(Hyla arborea* L.): Ökologie und Artenschutz. Mertensiella (6):1–200.

Contents of this issue are:

BORGULA, A. 1996. Langjährige Bestandesentwicklung einer kleinen Metapopulation des Laubfrosches (*Hyla arborea* L.) in der Schweiz. Mertensiella (6):7–26.

TESTER, U. AND C. FLORY. 1996. Zur Bedeutung des Biotopverbundes beim Schutz des Laubfrosches (*Hyla arborea* L.). Mertensiella (6):27–39.

STUMPEL, A.H.P. AND B.H.J.M. CROMBAGHS. 1996. Verbreitung und Situation des Laubfrosches (*Hyla arborea* L.) in den Niederlanden. Mertensiella (6):41–56.

MANZKE, U. AND R. PODLOUKY. 1996. Der Laubfrosch *Hyla arborea* L. in Niedersachsen und Bremen – Verbreitung, Lebensraum, Bestandssituation. Mertensiella (6):57–72.

MEIER, E. 1996. Bestansentwicklungen des Laubfrosches (*Hyla arborea* L.) in der westfälischen Bucht. Mertensiella (6):73–93.

BITZ, A., S. BLUM, H. SCHADER AND R. THIELE. 1996. Natur- und artenschutzrelevante untersuchungen am Laubfrosch (*Hyla arborea* L.) in Rheinland-Pfalz. Mertensiella (6):95–116.

GÜNTHER, R. 1996. Verbreitung und Lebensräume des Laubfrosches (*Hyla arborea* L.) in den Bundesländern Mecklenburg-Vorpommern, Sachsen-Anhalt, Brandenburg, Thüringen und Sachsen. Mertensiella (6):117–125.

GROSSE, W. -R. 1996. Vorkommen, Gefährdung und Schutz des Laubfrosches in Sachsen-Anhalt – Grundlagen für ein Artenhilfsprogramm. Mertensiella (6):127–148.

BERNINGHAUSEN, F. 1996. Erfolgreiche Laubfroschwiederansiedelung seit 1984 im Lankreis Rotenburg, Niedersachsen. Mertensiella (6):149–162.

PASTORS, J. 1996. Ergebnisse zweier Wiederansiedelungsprojekte des Laubfrosches (*Hyla arborea* L.) in Wuppertal – eine Langzeitstudie. Mertensiella (6):163–180.

Pleurodire Phylogeny

Araripemys is one of the three oldest pleurodires known for which the skeletal morphology can be completely described. Meylan took advantage of the completeness of the *Araripemys* specimens in preparing his redescription of *A. barretoi*. The data were incorporated into a phylogenetic analysis of pelomedusid (*sensu lato*) turtles. The results of the phylogenetic analysis suggest that there are four distinct clades in the Pelomedusidae.

MEYLAN, P. A. 1996. Skeletal morphology and relationships of the early Cretaceous side-neck turtle, *Araripemys barretoi* (Testudines: Pelomedusoides: Araripemydidae), from the Santana formation of Brazil. J. Vert. Paleontol. 16(1):20–33.

Salamander Biology

In an important contribution to our understanding of plethodontid diversity in southwestern México, Adler describes five new species of *Pseudoeurycea* from the Sierra Madre del Sur of Guerrero. Surveys conducted earlier in this century in the areas south of the Río Balsas had revealed a rich herpetofauna with high levels of endemism, but the salamander fauna was notably sparse with only a single species of *Pseudoeurycea* then recorded. Adler discusses the biogeography of the eight known species of salamanders from western Guerrero and notes that only *P. bellii* occurs outside of this region.

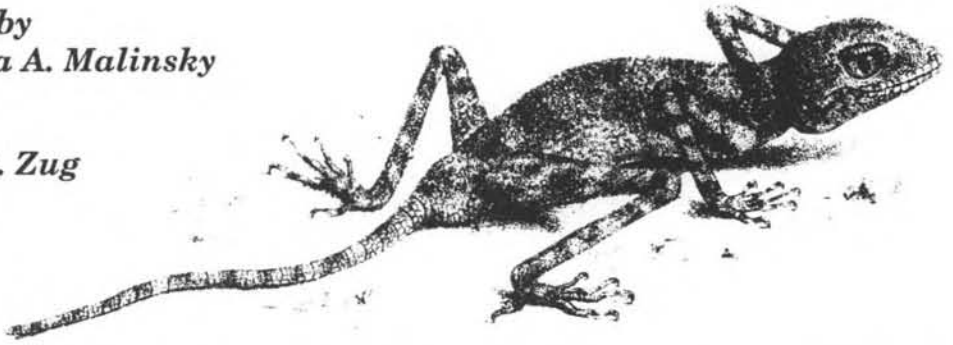
Pseudoeurycea teotepec, holotype (female), a newly-described species from Guerrero, México. From a water color by David M. Dennis.

ADLER, K. 1996. The salamanders of Guerrero, Mexico, with descriptions of five new species of *Pseudoeurycea* (Caudata: Plethodontidae). Occas. Pap. Nat. Hist. Mus. Univ. Kansas (177):1–28.

The largest known breeding migration of the flatwoods salamander (*Ambystoma cingulatum*) was monitored over a 22-year period. Nightly migrations of 200–300 adults in 1970–1972 had dwindled to less than one individual per night in 1990–1992. Means et al. discuss the possible natural and anthropogenic causes of the decline with special consideration of the effects of slash pine silviculture.

MEANS, D. B., J. G. PALIS, AND M. BAGGETT. 1996. Effects of slash pine silviculture on a Florida population of flatwoods salamander. Cons. Biol. 10(2):426–437.

Dawley and Crowder compared vomeronasal organ data through multiple regression by using total body size, sex, and season as variables that may influence vomeronasal organ volume in *Plethodon cinereus*. Their results indicate that total body size and sex significantly affect vomeronasal organ volume. During the sum-



A New Book from the Society for the Study of Amphibians and Reptiles

Gecko Fauna of the USSR and Contiguous Regions

by Nikolai N. Szczerbak and Michael L. Golubev

Translated from the Russian by Michael L. Golubev and Sasha A. Malinsky

Editorial supervision by Alan E. Leviton and George R. Zug

SZCZERBAK AND GOLUBEV'S BOOK, FIRST published in Russian in 1986, is the only comprehensive monograph on the Palearctic gecko fauna. **The book's scope is the entire gecko fauna of the former Soviet Union and related species in surrounding regions including Mongolia, western China, Afghanistan, and Pakistan through the entire Middle East to eastern Europe and northern Africa.** The genera covered are *Agamura, Alsophylax, Bunopus, Carinatogecko, Crossobamon, Eublepharis, Tenuidactylus* (equivalent to the Palearctic *Cyrtodactylus*), *Teratoscincus,* and *Tropiocolotes.* The deserts of Central and Southwest Asia have a large and diverse gecko fauna and this book covers 53 species (75 taxa including subspecies). The authors have had extensive experience with these geckos, both in the field and the laboratory, and much of their original data is given in this book. **The English translation has been corrected by Michael Golubev and updated by him with references to the recent literature (1986–1996).**

The book's contents include a review of previous work and a discussion of the relationships among genera. The taxonomic accounts cover all aspects of systematics and general biology: type locality, karyotype, synonymy, diagnosis, description of holotype, color and pattern, reproduction and growth rates, variation (ontogenetic, sexual, geographic), ecology and behavior (daily and seasonal activity patterns, natural predators, temperature relations, shedding, diet), and conservation. There are detailed lists of locality records and point locality distribution (or "spot") maps for each species. Keys are provided to genera, species, and subspecies. The book is extensively illustrated and includes **24 color photographs of geckos**.

• Professor Szczerbak, director of the Zoological Museum, Ukrainian Academy of Sciences in Kiev, is the author of several outstanding books on the herpetology—and especially on the desert lizards—of the former Soviet Union. Dr. Golubev, Szczerbak's former doctoral student, is a well-known specialist on geckos. He emigrated to the United States in 1993 and now lives in Seattle, Washington.

GECKO FAUNA OF THE USSR AND CONTIGUOUS REGIONS

***Specifications*:** 230 pages, 8 color plates (24 photos), 98 black-and-white figures (maps, graphs, and numerous photos of animals and their habitats), keys, bibliography, index. Format 7 × 10 inches (18.0 × 25.5 cm). Clothbound with dust jacket. To be published December 1996. ISBN 0–916984–39–7.

***Prices*:**		***Shipping*:**	
SSAR members *before publication*	US$35	In USA	add US$3
Institutions and Non-members	US$48	Non-USA	add US$5

***Send orders to*:** Dr. Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, 3507 Laclede Avenue, Saint Louis, Missouri 63103, USA (*telephone*: area code 314, 977–3916 or –1710; *fax*: 314, 977–3658; *e-mail*: ssar@sluvca.slu.edu). Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks (include an additional amount to cover bank conversion charges) or by International Money Order. Orders may be charged to MasterCard or VISA (provide account number and expiration date). SSAR membership details and a complete list of all Society publications can be obtained on request to Dr. Aldridge.

---

mer, both male and female *P. cinereus* have larger vomeronasal organs than at any other time during the year. The authors also discuss the functional significance of their findings.

DAWLEY, E. M., AND J. CROWDER. 1995. Sexual and seasonal differences in the vomeronasal epithelium of the red-backed salamander (*Plethodon cinereus*). J. Comp. Neurol. 359:382–390.

Turtle Conservation

Heppell et al. critically examined the population level effects of headstarting with a series of deterministic matrix models for yellow mud turtles (*Kinosternon flavescens*) and Kemp's ridley sea turtles (*Lepidochelys kempii*). Their results show that management efforts focused exclusively on improving survival in the first year of life are unlikely to be effective for long-lived species such as turtles. Proportional sensitivity analysis of stage-based matrix models indicated that annual survival rates for subadult and adult turtles are most critical; small decreases in the survival of older turtles can quickly overcome any potential benefits of headstarting.

HEPPELL, S. S., L. B. CROWDER, AND D. T. CROUSE. 1996. Models to evaluate headstarting as a management tool for long-lived turtles. Ecol. Appl. 6(2):556–565.

Herbivorous Frogs?

Rana hexadactyla is unique among anurans in that plants make up a large proportion of its diet. Das recently published a paper comparing the morphology of the gastrointestinal tract of *R. hexadactyla* to seven sympatric anurans. In a second paper Das examined the seasonal and ontological shifts in the diet of this unusual frog.

DAS, I. 1995. Comparative morphology of the gastrointestinal tract in relation to diet in frogs from a locality in south India. Amphibia-Reptilia 16:289–293.

DAS, I. 1996. Folivory and seasonal changes in diet in *Rana hexadactyla* (Anura: Ranidae). J. Zool., Lond. 238:785–794.

Snapping Turtle Systematics

Phillips et al. investigated relationships among the four currently recognized subspecies of *Chelydra serpentina* using RFLP of mtDNA and protein electrophoresis. Although allozyme variation among the four subspecies was limited, the mtDNA data presented support the species-level distinctness of *C. s. rossignonii* and *C. s. acutirostris* from each other and from a *C. s. serpentina–C. s. osceola* complex. The recognition of three *Chelydra* species is discussed.

PHILLIPS, C. A., W. W. DIMMICK, AND J. L. CARR. 1996. Conservation genetics of the common snapping turtle (*Chelydra serpentina*). Cons. Biol. 10(2):397–405.

Climate Model for Predicting Distribution

In order to predict the potential distribution of *Bufo marinus* in Australia, Sutherst et al. gathered temperature and moisture-related data from the known range of the species in the Americas. These data were used to set parameters for their CLIMEX model. Once the parameters had been determined and checked, the CLIMEX model was used to predict the potential distribution of *B. marinus* in Australia. In addition to the results, the techniques used in this paper could prove useful to other conservation programs.

SUTHERST, R. W., R. B. FLOYD, AND G. F. MAYWALD. 1995. The potential geographical distribution of the cane toad, *Bufo marinus* L. in Australia. Cons. Biol. 9(6:294–299.

The Snake

Since 1969 the Japan Snake Institute has been publishing the journal *The Snake*. As the title suggests, this journal publishes general papers on all aspects snake biology as well as medical papers on snake venoms and snakebite. *The Snake*, now in its 27th volume, consists of two issues per year. Subscriptions to the journal cost US$20.00/year. For more information write: The Japan Association of Snake Research, Yabuzuka-honmachi, Nittagun, Gunma Prefecture 379-23, Japan.

The Trade in Dendrobatid Frogs from 1987 to 1993

STEFAN GORZULA
Biosphere Consultants
614 West Main Street, Newbern, Tennessee 38059, USA

The inclusion of the dendrobatid frog genera *Dendrobates* and *Phyllobates* (*sensu* Frost 1985) on Appendix II of CITES has been criticized by a number of biologists (Bringsøe 1992; Campbell and Frost 1994; Mrosovsky 1988; Myers and Daly 1993; Pickett 1987). The process by which dendrobatids were added to the CITES appendices was initiated by Dutch and Surinamese participants at the 62nd Meeting of the Species Survival Commission (SSC) the IUCN held in Caracas, Venezuela, from 23–27 April 1987. Three proposals were put forward: the Republic of Suriname requested the inclusion of all members of the genus *Dendrobates* on Appendix II; the Netherlands requested the inclusion of all members of the genus *Phyllobates* on Appendix II; the Netherlands requested the inclusion of *Dendrobates altobueyensis* on Appendix I.

The supporting statements duplicated each other *verbatim* so that they appear to have been written by the same author or authors. The SSC requested reviews and advice from Charles Myers (USA), Marinus Hoogmoed (Netherlands), Stefan Gorzula (Venezuela), and Stephen Edwards (IUCN, Switzerland). Based on their responses, the IUCN recommended rejection of the proposals (IUCN 1987). Nevertheless, the Sixth Meeting of the Conference of the Parties to CITES, held in Ottawa, Canada, in July 1987 voted in favor of including both genera on Appendix II.

The listing of these two genera has been controversial since its inception. Arguments against the listing have expressed concern about scientific recommendations being ignored, the decision being influenced by politics, and the listing being unnecessary anyway (Bringsøe 1992; Campbell and Frost 1994; Mrosovsky 1988; Myers and Daly 1993; Pickett 1987). Supporters of the listing have been more cautious, implying that if there are any doubts then leave them on (Colwell 1994; Hoogmoed 1992; Jones 1994).

Nine years have passed since the Ottawa meetings. Given such a high level of polemic, I decided it would be useful to examine the extent of legal trade in specimens of dendrobatid frogs. This paper reviews the CITES trade data for dendrobatid frogs from 1987 to 1993.

Data documenting international trade in dendrobatid frogs were supplied by the World Conservation Monitoring Centre (WCMC), Cambridge, England. The WCMC, under contract from the CITES Secretariat, processes and stores all trade data supplied by Signatories to the Convention. Data were compiled from individual country reports.

The WCMC data consisted of a data base with 11 columns: the year that the trade occurred; the CITES Appendix of the species (in this case all species are in Appendix II); the species of dendrobatid frog; the type of material (live, bodies, specimens, or unspecified); the country of import; the country of export or re-export; the country of origin (if a re-export); the quantity imported; the quantity exported; the purpose of the shipment (e.g., commercial trade); and the source (taken from the wild, bred in captivity, confiscated). Due to delays in reporting by some countries, trade data for 1993 were considered incomplete (Lorraine Collins, pers. comm.).

The WCMC data were listed in such a way that for each individual shipment it could be determined whether that shipment was reported by the exporting country, by the importing country, or by both. However, the WCMC considered that some shipments would have been listed twice (once as an import only and once as an export only). Thus, the reported trade of 422 shipments consisting of 16,932 frogs and 200 g of scientific material was undoubtedly an overestimate of the true level of reported international trade. In an attempt to reduce this source of error, a computerized data base was prepared. Shipments were cross-matched by year, by importing and exporting countries, by species, and by quantity. Where, for example, the United States reported imports of 272 *D. tinctorius* from Suriname in 1992, these were considered to be the same 200 + 72 *D. tinctorius* reported exported as two shipments to the United States in 1992 by Suriname. In this way, the WCMC data were reduced to 394 shipments consisting of 15,779 frogs and 200 g of biological material.

The most recent checklist of CITES (Schouten 1992) follows Frost (1985) and does not use the more recent generic allocations of Myers (1987) and Zimmermann and Zimmermann (1988). The WCMC list generally follows Schouten (1992) with the exception that the WCMC places *Epipedobates azureiventris* in *Dendrobates* rather that in *Phyllobates*. I have used the generic and specific names exactly as they have appeared in the original sources.

A total of 15,779 individual dendrobatid frogs and 200 g of biological material were reported as traded internationally during the seven-year period from 1987 to 1993. Confiscated live frogs and specimens accounted for 1.1%. Bodies and specimens (excluding 200 g of material) made up 3.2%. Live wild-caught dendrobatids represented 82.6% and live captive-reared frogs 13.1% of the reported trade.

Only three consignments, totaling 173 dendrobatids frogs, were listed as seized. Dutch customs officials confiscated 13 live frogs and 150 "bodies" in 1989. Both shipments originated in Nicaragua. United States customs confiscated 10 "bodies" (source unknown) in 1992. These data suggest either that illegal trade is negligible or that it is not being detected.

There were 28 shipments of "bodies" and "specimens" comprising 502 frogs and 200 g of biological material. Twenty shipments were recorded as "for scientific purposes." The United States imported 3 bodies from Costa Rica, 42 from Ecuador, 1 from Guyana, and 383 + 200 g from Panama. Austria imported 14 bodies and Swaziland 4 from Ecuador, Germany 43 and Netherlands 10 from Costa Rica, and the United Kingdom 1 from Panama. A single *Dendrobates leucomelas* was exported from Venezuela to the Czech Republic. The annual trade figures for live dendrobatids are given in Table 1. There was a drop in international trade during 1990 and 1991. Captive-reared dendrobatids apparently took more of the market share in 1992 and 1993.

Twenty-six species of the 53 species of *Dendrobates* and *Phyllobates* listed in the most recent CITES checklist (Schouten 1992) were not registered in international trade. Four species (*D. tinctorius, D. pumilio, D. auratus*, and *D. trivittatus*) accounted for 94% of the trade in wild-caught dendrobatids identified to specific level. Such a strong bias towards a few species is less marked in captive-reared dendrobatids where the "top four" species (*D. auratus, D. tinctorius, D. tricolor,* and *P. vittatus*) make up only 66.5% of the trade.

TABLE 1. The annual primary trade (excluding re-exports) in wild-caught (Wild) and captive-reared (Captive) dendrobatid frog species from 1987 to 1993.

There is no evidence that any breeding stocks for eight of the species of dendrobatid frogs that figured in the international trade in captive-reared specimens were ever imported legally to the non-range producer nations during the period 1987–1993. These species, with the total numbers traded given in parenthesis, are: *D.(sic) azureiventris* (25), *D. azureus* (109), *D. bassleri* (8), *D. fantasticus* (44), *D. femoralis* (20), *D. leucomelas* (56), *D. truncatus* (11), and *P. terribilis* (84).

Sixteen countries reported exporting live dendrobatid frogs. Table 2 shows the yearly exports from the eight countries where dendrobatid frogs occur in the wild (A) and from eight countries where dendrobatid frogs do not occur naturally (B). With regard to the United States, a feral population of *Dendrobates auratus* occurs on the island of Oahu, Hawaii (Silverstone 1975). Suriname is the most important source of wild-caught dendrobatids and the Netherlands and Germany are the most important sources of cap-

TABLE 2. The yearly exports (including re-exports) from 1987 to 1993 of dendrobatids by: A, countries with wild populations of dendrobatids (Range countries) and B, countries without wild populations of dendrobatids (Non-range countries). Countries have been ranked in decreasing order of total exports.

tive-reared specimens. In Table 2, the total number of dendrobatids exported from non-range countries (2290) is higher than the total number of captive-reared specimens (2072) given in Table 1. This is due in part to the inclusion of re-exports of 120 wild-caught dendrobatids by the Netherlands, re-exports of 85 wild-caught dendrobatids by the United States, and re-exports of 8 captive-reared and 25 wild-caught dendrobatids by Germany. The remaining discrepancy involving 20 frogs was caused by Panama reporting 20 specimens of *D. pumilio* as captive-reared.

Table 3 (column 3) seems to suggest that the countries with wild populations of dendrobatids are more effective in reporting exports to the WCMC than the non-range countries. However, there are two notable exceptions. Peru exported 1794 dendrobatids in 9 shipments. None were reported to the WCMC; they were detected from the trade data of the importing nations (Germany, Netherlands, and United States). The Netherlands reported only 8 of its 63 export and re-export shipments to the WCMC.

Table 3 (column 5) also shows that the range countries tended to export more frogs per shipment (65.9) than the non-range countries (13.9). One explanation is that most of the exports by the range nations would be to major distributors, whereas the shipments from non-range nations would include many sales and exchanges between specialist breeders and institutions such as zoos.

The effectiveness of individual countries in reporting imports to the WCMC can be examined from Table 4 (column 3). Compliance with CITES requires export or re-export permits and/or certificates to be provided for Appendix II species, but does *not* require the issuance of import permits. Thus, imports would be more difficult to monitor than exports. Therefore, it is strange that the Netherlands has been more effective at reporting its imports (61.0%) than its exports (12.7%).

If the European Community (EC) countries (Belgium, Denmark, Germany, Netherlands, Spain, United Kingdom) are treated as a group (Table 4) the domestic market is of similar size to that of the United States. There are six members of the EC (France, Greece, Ireland, Italy, Luxembourg, Portugal) that apparently did not import or export any dendrobatid frogs from 1987 to 1993. However, there are three very important geopolitical anomalies that should be pointed out. First, French Guiana is an Overseas Department of France. Thus, any dendrobatids that were shipped to mainland France would not require CITES documentation. Secondly, Ireland is not a Party to CITES and therefore cannot issue CITES export permits and certificates. Finally, customs controls between EC nations were eliminated in January 1994.

The reported "purposes of export" on the 363 CITES export permits and/or certificates issued by the 16 exporting countries indicate that the majority of shipments (206) and dendrobatid frogs (11,674) were traded commercially (Table 5). The mean number of frogs/shipment for the shipments where the purposes of export were not reported (55.8%) is very similar to the mean number of frogs/shipment for the shipments where the purposes were reported as commercial trade (56.7%). This suggests that most, if not all, of these shipments were commercial.

Whereas figures are available for analyzing international trade, the magnitude of domestic trade and its trends can be examined only indirectly. From 1991 to 1993, the British Dendrobatid Group Newsletter (Numbers 4 through 18) published an extensive bibliography on dendrobatid frogs and mantellas. The dendrobatid bibliography listed 476 articles from scientific journals, popular magazines, and newsletters. In addition, 36 popular articles were published in the BDG newsletters. The non-scientific literature included many articles on the husbandry and captive rearing of

dendrobatids. Popular magazines that published five or more articles about dendrobatids are: Aquarien-Terrarien Zeitschrift (19), Aquarien Magazin Stuttgart (21), Aquarium Den Haag (10), Aquarium Wuppertal (5), Aquarium Aqua Terra (6), British Dendrobatid Group Newsletter (36), Dendrobatidae Nederland Magazine (53), Herpetofauna Weinstadt (15), International Society for the Study of Dendrobatid Frogs Newsletter (28), Bulletin of the International Society for the Study of Dendrobatid Frogs (5), Lacerta (30), Nordisk Herpet. Foren. (6), Salamandra (11), and Sauria (10). The numbers of non-scientific articles grouped into five-year periods are: 9 (1971/75); 31 (1976/80); 59 (1981/85); 111 + 1 book (1986/1990); 90 + 2 books (1991/92). These figures suggest that interest in dendrobatids among herpetoculturists is increasing.

In Europe there are at least three amateur groups organized *exclusively* for the study and rearing of dendrobatid frogs and mantellas. The British Dendrobatid Group was founded in 1989 and had 85 members in 1993. The Nederlandse Doelgroep Dendrobatidae was formed in 1988 and had 350 members in 1991. The Nordic Dendrobatid Society of Sweden began in 1991 and had 40 members by 1993. In Germany most dendrobatid enthusiasts belong to the Deutsche Gesellschaft Herpetologie und Terrarienkunde Arbeitsgruppe Anuren.

Herpetoculturists appear to be successful at breeding captive dendrobatids and mantellas. In 1991, British Dendrobatid Group members bred *Colostethus trinitatis, Dendrobates auratus, D. leucomelas, D. pumilio, D. ventrimaculatus* (= *D. quinquevittatus*), *D. tinctorius, D. truncatus, Epipedobates tricolor, E. azureiventris, Phobobates bassleri, Phyllobates vittatus, Mantella aurantiaca, M. crocea,* and *M. madagascariensis*. In 1990, members of the Deutsche Gesellschaft Herpetologie und Terrarienkunde Arbeitsgruppe Anuren bred *Colostethus elachyhistus, C. trinitatis, Dendrobates arboreus, D. auratus, D. azureus, D. granuliferus, D. leucomelas, D. pumilio, D. "quinquevittatus," D. speciosus, D. tinctorius, D. variabilis, Epipedobates anthonyi, E. boulengeri, Phyllobates tricolor, P.(sic) trivittatus, P. vittatus, Mantella aurantiaca,* and *M. crocea*. Neither *D. variabilis* nor *E. boulengeri* appear in Table 1.

Table 6 lists the dendrobatid frogs and mantellas kept by a group of British, Dutch, French, German, and Swedish hobbyists. It is interesting that they recognize distinct color varieties within at least three species (*Dendrobates auratus, D. pumilio,* and *D. tinctorius*). One hobbyist (Skillcorn 1993) reports that his frogs have produced hybrids *between* "*D. tinctorius* French Guyana (*sic*)" and "*D. auratus* West Coast." From a separate source in 1991, I also heard of the existence of *D. azureus/D. tinctorius* hybrids. Such occurrences suggest that there may already be recognizable varieties of captive dendrobatids which are not found in the wild.

The captive rearing of dendrobatids by hobbyists should not be regarded as simply keeping brightly-colored frogs in a terrarium. It is an expensive pastime that requires a substantial financial outlay. Dendrobatid frogs command rather high prices. The reports by Draper and Burnham (1992) about "Dutch Frog Day" in September 1992 and by Peaker (1991) about Dutch Frog Day in May 1991, as well as a price list circulated by a Dutch dealer in August 1991, give a range of retail prices for individual live dendrobatid frogs. The most expensive species was *Dendrobates azureus*

TABLE 3. The minimum number of shipments made by exporting nations between 1987 and 1993 (Total shipments), the number of shipments reported by export nations to WCMC (Shipments reported), the percentage of exports reported by these exporting nations to WCMC (% exports reported), the total number of dendrobatid frogs exported (Number of dendrobatids), and the mean number of dendrobatid frogs per shipment (Frogs/shipment). Countries have been separated into range and non-range countries and then ranked in decreasing order of the total number of dendrobatids exported.

quoted from US$56 to US$72. Next were *D. tinctorius* with prices from US$32 to US$68, depending on the color morph being sold. Medium-priced species included *Colostethus brunneus* and *Dendrobates quinquevittatus* at US$45 each, *Epipedobates azureiventris* at US$36, and *Phyllobates vittatus* at US$31. At the bottom of the range were *Dendrobates auratus* (US$9 to US$31), *D. leucomelas* (US$12 to US$40) and *Epipedobates tricolor* (US$9 to US$27). Tadpoles of all species were quoted at around US$9 each. All prices were calculated from current currency exchange rates.

The "Dutch Frog Days" are held at least twice each year. Davies and Davies (1991) mention that more than 600 dendrobatids were on sale at the September 1991 event. Given the previous figures, the total retail value of the dendrobatids offered for sale was in the order of US$25,000. Peaker (1991) reports that at the May 1991 "Dutch Frog Day" there were sellers from Belgium, Germany, and Holland. Buyers came from Belgium, Germany, Holland, the United Kingdom, and the United States. Peaker also noted that "some breeders had individual CITES certificates available." This observation is rather strange since CITES Management Authorities do not usually issue documents where the details of the importer are left blank for the exporter to fill in when he or she finds a buyer. Such an action, if correctly reported, would not be in compliance with the treaty.

Many scientists who claim to be affected by CITES have a less than adequate knowledge of the workings and purposes of the Convention. CITES is a dynamic treaty and its original text has been both qualified and clarified by nearly 200 Resolutions made at the nine Conferences of the Parties (held every two years from 1976 to 1994) as well as at the 1977 Special Working Session. Any biologist with an interest in international wildlife trade issues should study a reference text (e.g., Wijnstekers 1992) and routinely read journals and newsletters such as *TRAFFIC Bulletin, Endangered Species UPDATE,* and *Traffic USA*.

CITES has nothing to do with the use of wild fauna and flora within a member nation. CITES has nothing *whatsoever* to do with habitat protection within a member State. Many species of fauna and flora threatened with extinction *are not included* in CITES and *should not be included* in CITES. Red Data Book and similar endangered species listings and CITES appendices are not synonymous.

The acronym CITES stands for the **Convention on International Trade in Endangered Species of Wild Fauna and Flora**. The three words "International," "Trade," and "Wild" are the essence of the treaty. Many authors inadvertently omit the word "Wild" (Bringsøe 1992, Campbell and Frost 1994, Jones 1994, Myers and Daly 1993, Pickett 1987). This suggests that many editors and reviewers also are not familiar with the full text of CITES.

CITES does not prohibit scientific collection. Article VII, paragraph 6, even provides an exemption for "non-commercial loan, donation or exchange between scientists or scientific institutions registered by a management authority of their State." The fact that individual countries are making it more difficult for foreign

TABLE 4. The minimum number of shipments received by importing nations between 1987 and 1993 (Total shipments), the number of shipments reported by importing nations to WCMC (Shipments reported), the percentage of imports reported by these importing nations to WCMC (% exports reported), the total number of dendrobatid frogs imported (Number of dendrobatids), and the mean number of dendrobatid frogs per shipment (Frogs/shipment). Countries have ranked in decreasing order of the total number of dendrobatids imported. The last row gives the data for the European Community after subtracting the imports between member nations.

scientists to carry out independent work is a separate issue, and may have more to do with external institutions obtaining the more direct and exclusive benefits of such activities (Huber and Gorzula 1986).

Species on Appendix II are those "which although not necessarily now threatened with extinction may become so unless trade in specimens of such species is subject to strict regulation in order to avoid utilization incompatible with their survival" (Article II, paragraph 2a) and "other species which must be subject to regulation in order that trade in specimens of certain species referred to in subparagraph (a) of this paragraph may be brought under effective control" (Article II, paragraph 2b). "Trade" is the "export, re-export, import and introduction from the sea" (Article I, subparagraph c). An animal "specimen" means alive or dead animals and any recognizable parts or derivatives (Article I, subparagraph b). Article IV, paragraph 2, requires that export permits shall only be granted for Appendix II species when "a scientific authority of the State of export has advised that such export will not be detrimental to the survival of the species."

In the case of wild-caught dendrobatids, it is important to put the trade figures into perspective. As a very crude illustration, the total number of dendrobatid frogs legally exported from the range countries over a seven-year period would not have filled a large trash can! Do we believe that this level of trade was detrimental to the survival of dendrobatids in Central and South America?

Finally, the total retail value on the domestic markets of the importing nations of *all* wild-caught dendrobatids shipped between 1987 and 1993 would have been less than US$500,000. Based upon my experiences with the international wildlife trade, I doubt whether even one third of that amount would have entered the economies of the producer nations. However, the export of dendrobatids from a country such as Suriname, with a human population of about 420,000 and a per capita national product 14% of that of the United States, could be of marginal significance to its economy.

Acknowledgments.—Lorraine Collins and John Caldwell of the World Conservation Monitoring Centre (Cambridge, England) kindly supplied me with the international trade data.

and

JEAN BEASLEY
Topsail Turtle Project, P.O. Box 2663 Surf City, North Carolina 28445, USA

Sightings of numerous leatherback turtles (*Dermochelys coriacea*) in association with, and feeding on, cabbagehead jellyfish (*Stomolophus meleagris*) during a brief time period (May and June 1990 and 1991) within 300 m of the beach at North Topsail Beach, Onslow County, North Carolina, USA (Grant and Ferrell 1993) suggested a seasonal relationship. No peak seasonal pattern of leatherback occurrence in North Carolina waters was evident in the review by Lee and Palmer (1981). However, in a summary of publicly reported sightings between 1989 and 1992, leatherback abundance was highest in May and June (Epperly et al. 1995a).

This paper presents nearly simultaneous survey data for both leatherback turtles and cabbagehead jellyfish to more accurately assess the duration of abundance of both species and determine the extent of co-occurrence in nearshore waters along the North Carolina coast.

Aerial censuses were conducted along the 41.6 km coastline of Topsail Island, North Carolina, 20 April–13 July 1992, 20 April–22 June 1993, 2 May–11 July 1994, and 3 May–7 July 1995. Two transects parallel to the shoreline, about 500 m and 1000 m offshore, were flown in a Cessna 172 along the entire length of Topsail Island. Turtles seen on either side of the aircraft, up to about 250 m, were counted. Flight altitude varied from about 150 m to 220 m and flight speed was 140–150 km/hr (see Marsh and Sinclair 1989, for evaluation of aerial survey techniques). Observers reported all turtle sightings, while we verified and recorded all sightings on data sheets. Censuses were conducted between 1000 and 1600 h for 35–55 min on days with good visibility and light winds. Time of day, glare, and time of high tide had no significant impact on the observed densities of turtles in a study conducted by Marsh and Sinclair (1989).

Two types of cabbagehead jellyfish censuses were concurrently undertaken. From 2.0–4.7 km of the beach of North Topsail Beach were walked on the day of the aerial surveys in 1992 and 1995. All beached jellyfish were counted and removed from the beach to avoid counting the same ones on a later census. Because jellyfish were not removed the day before a given beach count, the numbers reported actually sample more than one day. However, most counts were made at about weekly intervals. Strong on-shore winds would probably increase the numbers of beached jellyfish. However, no significant storm systems occurred during the census periods.

The second jellyfish census area was a 200 m x 40 m transect strip observed from Salty's Pier in 1992 and from all six piers on Topsail Island in 1995; all were made on the day of the aerial turtle surveys. All jellyfish seen in the water within 20 m on either side of the distal 200 m of the pier(s) were counted. Qualitative estimates of jellyfish were made from the piers in 1993 and

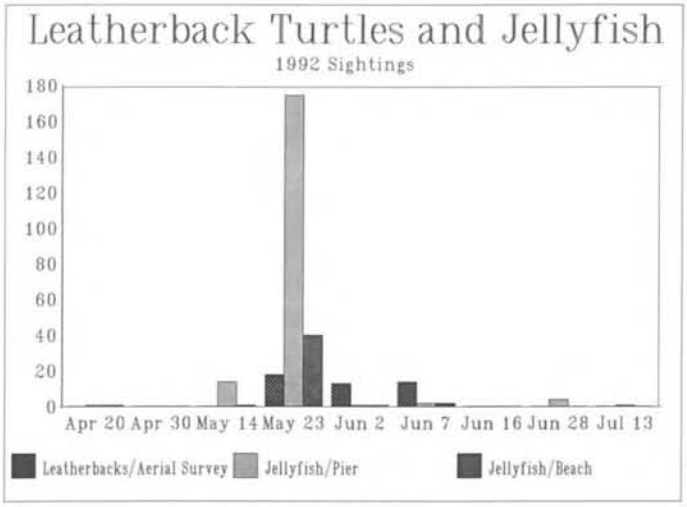

FIG. 1. Leatherback turtle and jellyfish censuses on Topsail Island, North Carolina during 1992.

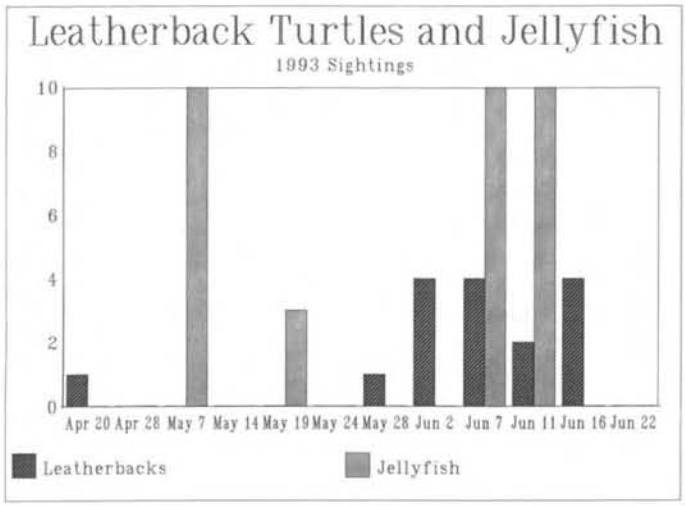

FIG. 2. Leatherback turtle and jellyfish censuses on Topsail Island, North Carolina during 1993.

1994. Relative numbers of jellyfish were ranked on a 0 (none) to 10 (abundant) scale during the 1993 and 1994 surveys.

A total of 45 leatherback turtles was sighted on three (23 May, 2 June, and 7 June) of the 9 censuses in 1992 (Fig. 1). Forty (88.9%) of the leatherbacks counted during the surveys were on the near-shore transect (500 m). Twenty-two of these were <500 m offshore; some were sighted just offshore of the breakers. Only 3 (7.7%) leatherbacks were sighted >1000 m offshore. Leatherback numbers in 1992 were highly correlated with jellyfish numbers (both pier and beach surveys). Sixteen leatherbacks were sighted during aerial surveys in 1993 and the correlation with jellyfish abundance was less pronounced (Fig. 2). Eleven leatherbacks were counted during censuses in 1994 and the correlation with jellyfish abundance was not strong (Fig. 3). Only 6 leatherbacks were counted during the 1995 surveys. The 1995 jellyfish surveys from the piers revealed two small peaks in May. However, daily jellyfish abundance varied tremendously from one pier to the next, even though any one pier survey was completed within 15 minutes of the next (Fig. 4). No beached jellyfish were found during the 1995 surveys. The average number of leatherbacks sighted per survey dropped tremendously from 1992 to 1995 (Fig. 5). The apparent decrease may be due to a number of factors including declining populations, different cohorts during different years, and movement further offshore.

Maximum water depth in the survey area was about 10 m. Thus, all leatherbacks were seen in water 2–10 m deep. Such shallow water movements have been reported inside bays along the Gulf coast of Florida (Yerger 1965) and off the Texas coast (Leary 1957).

We saw turtles as much as 1–2 m below the surface. Some turtles were probably missed due to deeper submergence. Therefore, the numbers of turtles reported are minimum counts. The two parallel transects sampled an area about 1.0 km wide and 41.6 km long (length of Topsail Island), for a total area of 41.6 km^2. Leatherback density ranged from 0–34.6/100 km^2 along Topsail Island. Thompson (1984) reported a spring density of 0.02–2.99 turtles/100 km^2 (all species) between Cape Hatteras, North Carolina, and Key West, Florida. Keinath et al. (1987) reported spring densities of 0–57.5 turtles/100 km^2 (all species) for the lower Chesapeake Bay, Virginia. Densities as high as 30.48 turtles/100 km^2 (all species) have been observed in Core Sound, North Carolina (Epperly et al. 1995b). Leatherback density off the eastern coast of Florida was estimated to be 3.2 x 10^{-3} /km^2 to 0.01 turtles/km^2 (Fritts et al. 1983) and density estimates in waters of the northeastern United

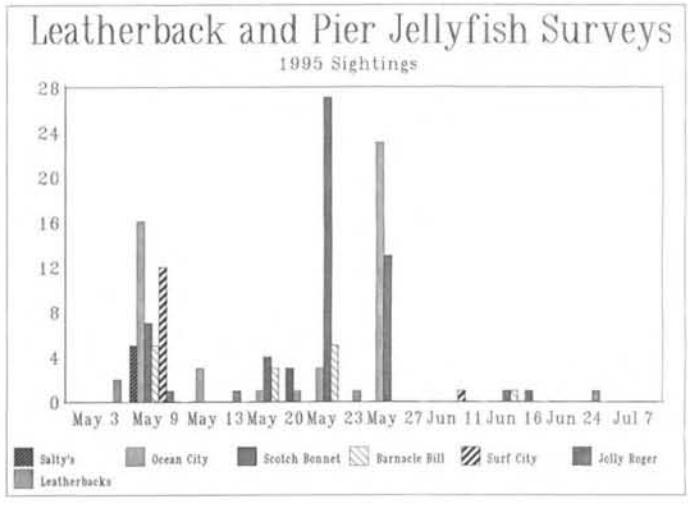

FIG. 4. Leatherback turtle and jellyfish censuses on Topsail Island, North Carolina during 1995.

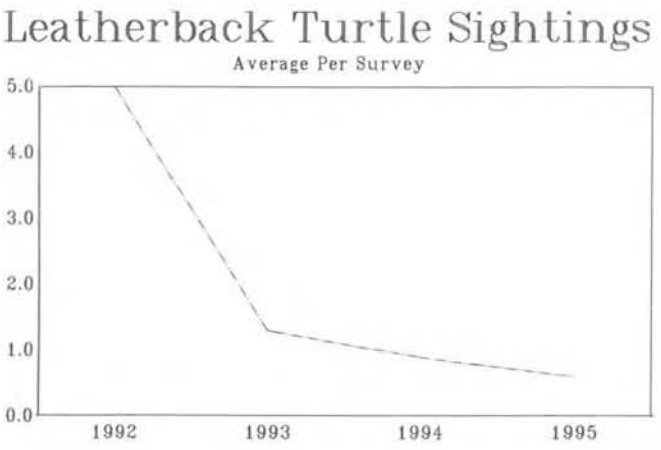

FIG. 5. Mean number of leatherback turtles per survey from 1992–1995.

States ranged from 2.09 x 10^{-3} to 2.16 x 10^{-2} /km^2 (Shoop and Kenney 1992).

Short-term abundance of leatherback turtles was documented by Knowlton and Weigle (1989) along the coast of Florida between Daytona Beach and Cape Canaveral. They counted 168 leatherbacks in mid-February 1988. Their next census (16 March 1988) in the same area revealed no leatherbacks. Large numbers (40) were stranded along the Georgia coast in April 1991 (Georgia Sea Turtle Stranding Network 1991). Leatherback numbers in North Carolina (this study; Epperly et al. 1995a) peaked in May and early June. Leatherback sightings peaked in Cape Cod Bay, Massachusetts, in August and September (Prescott, 1988). Most leatherbacks sighted by Shoop and Kenney (1992) off the coast of the northeastern United States occurred during the summer (defined by them as 21 June–20 September). Large numbers seen for a brief time interval in February off Florida, April off Georgia, May–June off North Carolina, and August–September off Massachusetts suggest that a portion of the population may regularly move north along the east coast of the United States during this time of the year.

Peak numbers of leatherback turtles within 1 km of the shoreline in this study were correlated with peak jellyfish numbers in 1992 but not other years when jellyfish appeared to be patchily distributed. Leary (1957) observed about 100 leatherbacks within a dense school of cabbagehead jellyfish near the Texas coast.

Acknowledgments.—We thank G. Gunter of Topsail Scenic Flights for the use of his airplanes and F. Linker for aid with the figures. J. Braun made available unpublished data collected by the National Marine Fisheries Service, Beaufort, North Carolina. J. Braun, R. A. Seigel, and two anonymous reviewers improved this manuscript. Funding was provided by the North Carolina Nongame and Endangered Wildlife Fund and the Topsail Turtle Project.

Home Range Size of the Hellbender (*Cryptobranchus alleganiensis*) in Missouri

CHRIS L. PETERSON
Division of Science and Mathematics, Cottey College
Nevada, Missouri 64772, USA

and

ROBERT F. WILKINSON
Department of Biology, Southwest Missouri State University
Springfield, Missouri 65804, USA

Knowledge of patterns of activity and use of space is important for understanding the natural history of a species (Weatherhead and Hosak 1989). Size, shape, and overlap of home range have been related to food density, metabolic needs, population density, and territoriality (Alberts 1993; Brown and Orians 1970; Schoener 1968; Simon 1975). Also, knowledge of home range is important to predict the effects of environmental disturbance on a species (Hill and Grossman 1987). The hellbender (*Cryptobranchus alleganiensis*) has declined in numbers or been extirpated in portions of its range due to human activities (Nickerson and Mays 1973; Trauth et al. 1992; Williams et al. 1981). The only published information on home range of hellbenders was provided for a population in western Pennsylvania (Hillis and Bellis 1971). However, nearly half of the estimates of home range size were based on two observations of an individual, and no individual was captured more than five times. We were interested in determining size of home range of hellbenders in Missouri based on numerous recaptures.

The study site was an 80 m long section of Niangua River, Missouri, USA. Maximum depth was 1.5 m. Along the southern bank, gravel extended 5–10 m into the river. Along the northern shore, areas of silt extended 3–5 m into the river. Large rocks were numerous in the center of the site. Bedrock was present at the downstream end with few large rocks. At the upstream end, gravel extended to midstream with bedrock and a few large rocks on the northern side. We sampled the site 33 times between 15 August 1989 and 31 January 1990 by turning rocks during daylight and catching hellbenders by hand. All rocks were repositioned whether or not they sheltered a hellbender. The mean and maximum intersample periods were 5.5 and 23 days.

The first time a hellbender was captured, it was anesthetized in a weak tricaine (3-aminobenzoic acid ethyl ester, Sigma Co.) solution, branded on the venter with a unique number, sexed, and measured for snout-vent length (SVL). It was then returned to the rock where captured. For all subsequent captures of a marked individual, the brand was noted, and the individual was immediately released under the rock where captured. The location of each rock that sheltered a hellbender was mapped. A brick with a number was placed beside the rock to identify it.

Home range size was estimated by determining the size of a minimum area convex polygon (MCP; Mohr 1947). Jenrich and Turner (1969) reported that the MCP method can have large bias if the number of observations is small. However, with enough observations, home ranges estimated by the MCP method should approximate the true home range (Schoener 1981). We did not determine the home range of any hellbenders captured fewer than 14 times. However, three individuals captured more than 15 times were found only under a single rock, and two individuals were captured under only two rocks. We assigned a home range size of zero square meters to the former three and determined a mean activity radius (MAR) to estimate a circular home range (Hayne 1949) for the latter two. A MAR was calculated for hellbenders captured by Hillis and Bellis (1971).

TABLE 1. Home range size for hellbenders captured 14 or more times.

Home Range (m^2)	SVL (cm)	No. Times Captured	Time Interval (days)	No. Rocks Used as Shelter
		Females, N = 14		
0.0*	30	33	169	1
0.0*	32	33	169	1
0.4	28	31	159	3
1.8*	28	16	67	2

* Hellbenders for which a minimum convex polygon could not be constructed. A mean activity radius was calculated to estimate the home range size for the two hellbenders captured under only two rocks.

Twenty-five adult females and 25 adult males were captured at least once. No juveniles were captured. Twenty-four hellbenders were captured nine or fewer times (19 were captured fewer than 5 times). The remaining 26 hellbenders were captured 14 or more times (Table 1). Five individuals were captured in all 33 samples, including two females each captured only under a single rock. Eighteen of the individuals in Table 1 were captured on the first day of sampling. Twelve hellbenders captured during the first sample were also captured during the last sample.

For females, average home range size was 28 m^2 (SE = 8.2). Median home range size was 13 m^2. If the three females caught under only one or two rocks (indicated by asterisks in Table 1) were deleted from the analysis, average home range size would be 36 m^2. For males, average home range size was 81 m^2 (SE = 18.7). Median home range size of males was 77 m^2. If the two males captured under only one or two rocks were deleted, average home range size would be 95 m^2. A Mann-Whitney U-test indicated that males had a significantly larger home range than did females ($U = 126$, $0.05 > P > 0.02$). There was no significant

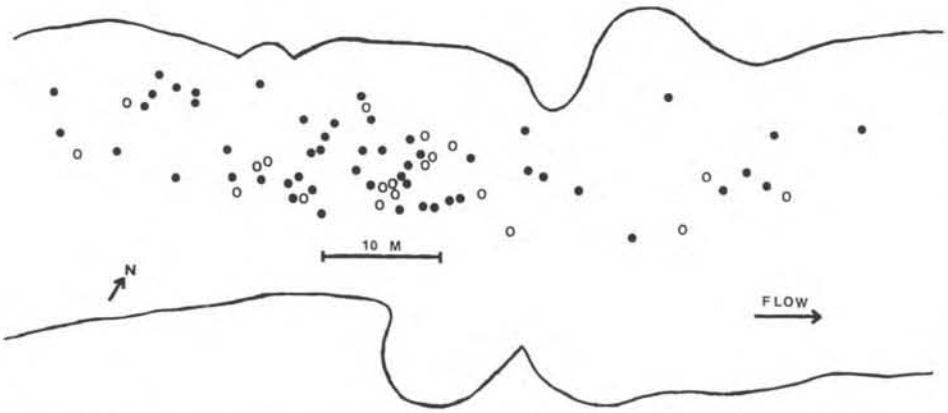

FIG. 1. Study site in Niangua River, Missouri. Dots indicate rocks used as shelter by hellbenders throughout the study. Open circles indicate rocks where hellbenders were captured during the first sample.

product-moment correlation between SVL and home range size for females (r = 0.20) or males (r = -0.12) or between home range size and number of times captured for females (r = 0.04) or males (r = 0.31).

There was considerable overlap in home ranges of both male and female hellbenders. All but three of the hellbenders in Table 1 sheltered at least once under a rock in the 10-m section indicated in Fig. 1. Also, some rocks served as shelter for more than one hellbender at different times. Thirty rocks were used by one hellbender only, 18 by two hellbenders, 10 by three hellbenders, six by four hellbenders, three by five hellbenders, four by six hellbenders, and one rock was used by seven hellbenders. However, we never observed more than one individual under the same rock during a sample. Only six captures of hellbenders were made away from shelters, and each such capture was made during September when breeding occurs (Peterson 1988; Peterson et al. 1989a).

Hillis and Bellis (1971) reported an average home range size of 346 m^2 (median = 113 m^2) for 73 hellbenders and found no significant difference in the MAR between sexes. We calculated only three home ranges as large as the median home range estimate of Hillis and Bellis (1971). The smaller estimates of home range we calculated may have been due in part to a smaller study area (80 m x 25 m compared to 220 m x 70 m) and the possibility that home ranges overlapped our upstream or downstream borders. However, we believe the major difference in estimates is due to the methods of calculating home range: circular versus MCP in a basically linear habitat. Also, Hillis and Bellis (1971) may have calculated home ranges for transients because only 13 of the 73 hellbenders were captured more than three times.

Coatney (1982) determined an elliptical home range size of 90 m^2 for seven Ozark hellbenders based on nocturnal telemetry over a period of at most two weeks. Again, our estimates are generally smaller, despite presumably greater disturbance of hellbenders due to capture by hand rather than telemetry. This may be due to the nocturnal habits of hellbenders and a tendency to return to a "home rock" at dawn (Coatney 1982). Perhaps this was the case with the three hellbenders we caught only under the same rock. However, because their diet is mostly crayfish (Nickerson and Mays 1973; Peterson et al. 1989b), hellbenders may be predominantly sit-and-wait predators.

We found considerable overlap in home ranges. Coatney (1982) thought that hellbenders with overlapping ranges avoid being in the area of overlap simultaneously, and rarely has more than one hellbender been found under the same rock except during the breeding season (Hillis and Bellis 1971; Nickerson and Mays 1973; Peterson 1988; Smith 1907). We have observed vigorous defense of shelters in aquaria by both sexes, and males similarly defended shelters containing eggs in natural habitats (Peterson 1988; Smith 1907). Hillis and Bellis (1971) also reported defense of a shelter, but stated that hellbenders were very opportunistic in occupying a cover rock recently vacated by another hellbender. Our data of multiple use of a rock by different hellbenders support their observation. We hypothesize that active defense in a home range is limited to a shelter.

Addenda to Checklist of Scientific and Common Names of Mexican Amphibians and Reptiles

ERNEST A. LINER
310 Malibou Boulevard
Houma, Louisiana 70364-2598, USA

The following corrections and additions apply only to Liner's Checklist (1994) as published (cut-off date, 30 September 1993). New Mexican taxa described in 1994 and 1995 are omitted and reserved for inclusion in a contemplated second edition. Changes include minor errors of commission and misspellings, and shifts in taxonomic status. Previously overlooked Mexican taxa or proposals of new taxa (with suggested common names) are marked with an asterisk.

A new species, *Gerrhonotus aquayoi* (Contreras-Arquieta 1989), published in a resumen is not a valid description by present standards and is excluded. The book by Golay et al. (1993) is omitted as some changes in the status of Mexican forms are not documented.

I have been asked often why several taxa in the checklist have been elevated to species status. This was done on the basis of papers by Frost and Hillis (1990) and Collins (1991). Collins (1991) provided a list of U.S. forms—distinct at the species level in his opinion—camouflaged as subspecies. Some of these forms occur in México as well. The following Mexican taxa were elevated to specific rank: *Bufo microscaphus californicus, Kinosternon flavescens arizonense, Pseudemys concinna gorzugi, Cnemidophorus burti xanthonotus, Crotaphytus insularis vestigium, Holbrookia lacerata subcaudalis, Sceloporus graciosus vandenburgianus, Uta stansburiana stejnegeri, Arizona elegans occidentalis* and its subspecies, *Coluber constrictor mormon, Masticophis bilineatus lineolatus, Micrurus fulvius tener* and its Mexican subspecies, *Pituophis melanoleucus catenifer* and its Mexican subspecies, and *Tantilla rubra rubra*.

The following corrections are noted (page number from the original publication precedes the correction):

p. 3—Table corrections are Testudines 31 ssp. instead of 32; Sauria 241 ssp. instead of 242; Totals of taxa 1537, of subspecies 581.

p. 12—*Ensatina e. eschscholtzii* (= Monterey instead of Monterrey).

p. 12—*Ensatina e. klauberi* (= *E. klauberi* by Frost and Hillis 1990).

p. 21—*Eleutherodactylus terestes* (=*teretistes*).

p. 35—*Trachemys scripta grayi* (alphabetically should follow *T. s. elegans*).

p. 36—*Abronia kalaina* (not recognized, synonym of *A. fuscolabialis*, Campbell and Frost 1993).

p. 36—**Abronia leurolepis* Campbell and Frost 1993...Smoothback Arboreal Alligator Lizard (Dragoncito Espaldasuave).

p. 36—**Abronia smithi* Campbell and Frost 1993...Smith's Arboreal Alligator Lizard (Dragoncito de Smith).

p. 37—*Anniella pulchra nigra* (delete, not member of Mexican fauna).

p. 38—*Cnemidophorus*. Two interrelated papers (Wright 1993; Wright 1994—hereafter abbreviated W-1993, W-1994) have altered the entries under this genus.

p. 38—*C. alpinus* (not recognized, synonym of *C. costatus costatus*, W-1993:80).

The important reviews of classification, phylogeny, and distribution of the members of the genus *Cnemidophorus* by Wright (1993, 1994) recognize three, largely parapatric lineages of spotted whiptail lizards in the *sexlineatus* species group. The eastern group contains *C. gularis*, the western group *C. burti* and *C. costatus*, and the central group a species referred to as *C. septemvittatus*.

It is the first and fourth names to which attention is here directed. The name *C. gularis* Baird and Girard (1852) is the earliest by far of all names applied to these groups. The names proposed for taxa in the central group all have long been thought to have appeared simultaneously in a work by Cope (1892b): *C. septemvittatus*, p. 40; *C. gularis scalaris*, p. 47; *C. g. sericeus*, p. 48; and *C. g. semifasciatus*, p. 49. That work appeared about May 4, when reprints were printed; mailing of the journal as well as reprints no doubt took place within a few days of that date.

On the contrary, Cope (1892a) had earlier (March 1, 1892) published descriptions of two (*C. g. scalaris*, *C. g. semifasciatus*) of the four treated in the later review (1892b); *C. septemvittatus* and *C. g. sericeus* were not mentioned in the earlier work.

The first article is essentially an abstract or notice, the likes of which Cope as editor then of the *American Naturalist* frequently contributed in advance of his own, more elaborate subsequent publications elsewhere. Nevertheless the characterizations provided in this notice for both *C. g. scalaris* and *C. g. semifasciatus* are without question adequate for nomenclatural availability under Art. 12(a) of the 1985 edition of the International Code of Zoological Nomenclature (hereinafter the "Code"): "To be available every new scientific name published before 1931 must... have been accompanied by a description or a definition of the taxon that it denotes, or by an indication."

The pertinent text in Cope (1892a) follows: "The first modification [in a series of geographical variants] is seen in the appearance of pale spots in the interval between stripes, a character which partly defines the *C. gularis* B. & G. These spots are greatly enlarged in the *C. gularis scalaris* Cope, joining the stripes and breaking up the ground color into spots.... Returning to *C. g. scalaris*, the dark spots may be confluent transversely, forming a transversely banded form. This transverse banding commences at the posterior extremity of the body.... [p. 1136] When the color pattern consists of rows of oblong black spots on a dark ground the form *C. g. semifasciatus* Cope is produced."

The relationships of the various taxa denoted by these five species-group names (*gularis*, *scalaris*, *semifasciatus*, *septemvittatus*, *sericeus*) have been differently interpreted by different workers over the past several decades. Some regard all as subspecies of *C. gularis*, whereas others recognize as many as three species, the names for which (excluding *C. gularis*) hitherto have depended on the relative priorities of the four names supposedly published simultaneously by Cope (1892b).

With the discovery of the earlier descriptions (Cope 1892a), it is obvious that *scalaris* and *semifasciatus* have priority over *septemvittatus* and *sericeus*. Although *scalaris* (p. 1135) has page priority over *semifasciatus* (p. 1136), and *septemvittatus* (p. 40) over *sericeus* (p. 48), nomenclatural priority is established in each case by application of the "Principle of the First Reviser." In brief, according to that Principle (Art. 24(a) of the Code), "If two or more names,... published on the same date,... are considered to be synonyms,... their relative precedence is determined by the first reviser.... The first author to have cited together such names... has determined the precedence of the chosen name...." Essentially the same information was given in the 1961 edition of the Code.

No reviser has ever dealt with the two names as proposed by Cope (1892a). On the basis of frequency of usage, we here assign priority to *scalaris* over *semifasciatus* whenever those taxa are regarded as synonyms at either specific or subspecific levels.

Only two names proposed by Cope in the later review (1892b) actually are new, among those considered here: *septemvittatus* and *sericeus*. The relative priority of these particular two names has never been assigned. On the basis of frequency of usage, we here select *septemvittatus* over *sericeus*.

As unsettled as the taxonomy of this group has been in the past, the authority of the automatic provisions of the Code is a welcome anchor adaptable to whatever arrangement will be dictated by future research. No appeal for arbitration is justified.

TECHNIQUES

A New Device for Capturing Small and Medium-Sized Lizards by Hand: The Lizard Grabber

BRIAN W. WITZ

Department of Biology, University of South Florida
Tampa, Florida 33620, USA

Present address: Department of Biology, Nazareth College

e-mail: bwwitz@naz.edu

Capturing lizards with the assistance of sling shots and rubber-band guns, or simply by shooting large rubber bands launched from the fingers is described by Conant and Collins (1991). However, they preferred capturing lizards with a noose, because the chance of injury is reduced considerably with this method. Noosing is a useful technique that can be quite successful when mastered, but it is not without its problems. Many saurologists find that slipping a noose over the head of a lizard is difficult because lizards either become startled or attempt to bite the thread as it approaches their head. Because it is difficult to cinch the noose tightly around the lizard's body or neck, many individuals escape.

An automobile mechanic's bolt retriever may be modified to function as a "lizard grabber." I have used this lizard grabber to capture *Cnemidophorus sexlineatus*, *Anolis sagrei*, *A. carolinensis*, and *Sceloporus undulatus*. Lizards wider than 20 mm at the pelvic girdle cannot be captured with the lizard grabber as described herein, but additional modifications will increase its applicability.

The basic device may be purchased at any automotive parts store or in the automotive section of many department stores. These tools are available in a variety of lengths. The device I used had a total length of 60 cm. The unmodified device consists of a tightly-

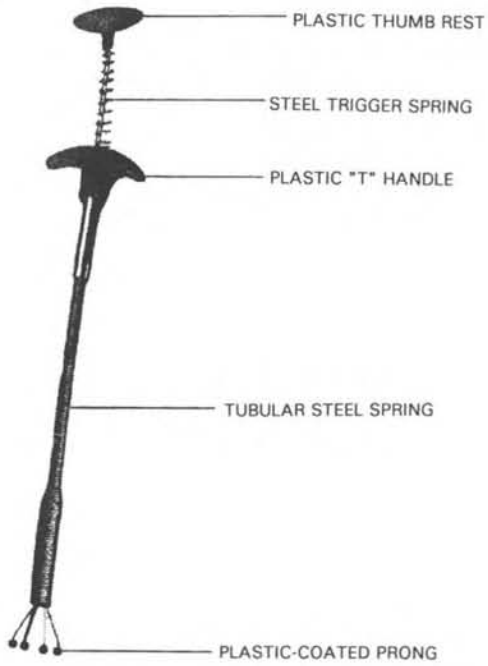

Fig. 1. The Lizard Grabber ("loaded" state). Total length of the device is ca. 60 cm.

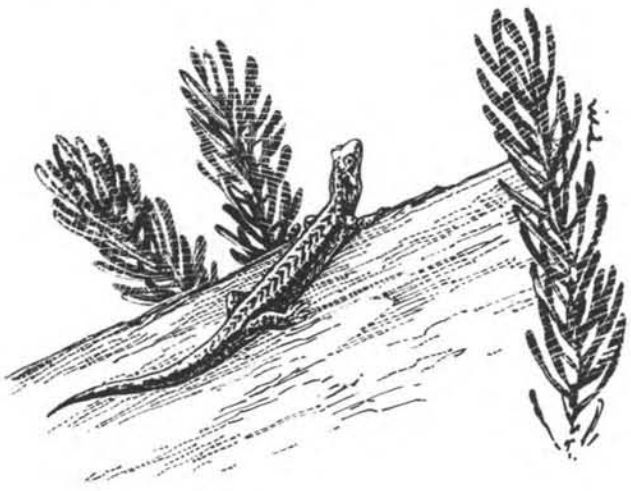
wound, tubular steel spring, ca. 500 mm long, capped with a plastic "T" handle that is attached to the spring with a steel collar (Fig.1). The outside diameter (OD) of the spring is 5 mm along most of its length; the distal 50 mm is expanded to ca. 8 mm OD. A hollow aluminum rod (3 mm OD), capped with a plastic thumb rest, runs through the center of the steel spring and extends ca. 60 mm beyond the "T" handle. This 60 mm length of aluminum rod is enclosed within a 10 X 50 mm steel trigger spring which, when the device is not loaded, rests in a slightly compressed state between the "T" handle and the thumb rest cap. Four spring-loaded, aluminum prongs are attached to the distal end of the aluminum rod. When the device is not loaded, the prongs remain collapsed inside the expanded distal end of the tubular steel spring.



Two modifications of the basic device are necessary. To prevent injury to lizards, the first modification involves coating the sharp tips of the aluminum prongs with liquid plastic. The prongs should be held in an expanded state by squeezing the trigger in a vice or wood clamp, and then dipped in liquid plastic and allowed to dry for several hours. I suggest using two coatings. As purchased, the "Grabber's" trigger spring tension can be sufficient to injure some lizards. If this spring is shortened by cutting and removing 1–2 coils, the spring tension will be reduced.

Using the lizard grabber, an investigator can capture an unsuspecting lizard from behind, an advantage over the noose which must be slipped over the lizard's head. I approach lizards from behind and position two of the plastic-coated prongs anterior to, and two posterior to, the hind limbs. All four prongs must be placed close to the lizard's body. When the thumb rest is released, the prongs grab the pelvic girdle firmly, with minimal chance of escape or injury to the lizard.

Acknowledgments.—The lizard grabber was used during my doctoral dissertation research project at the University of South Florida. Funding, in part, was provided by grants from Sigma Xi and the University of South Florida Center for Urban Ecology. Thanks to H. R. Mushinsky and E. D. McCoy for their guidance throughout my graduate career, and to MaryJo A. Witz for proofreading the manuscript.

Mist Netting: Adapting a Technique from Ornithology for Sampling Semi-Aquatic Snake Populations

WILLIAM I. LUTTERSCHMIDT
and
JACOB F. SCHAEFER
Department of Zoology, University of Oklahoma
Norman, Oklahoma 73019, USA

Mist nets, used by ornithologists to entangle birds, are expensive due to the design and use of cotton or nylon shelf strings creating hammocks in the net (Bub 1991). We describe a snake "mist net" that works similarly but is made from an inexpensive black polypropylene netting sold as protective fruit-tree netting at most garden centers. A 28 X 28 ft. (8.5 X 8.5 m) Bird-X® (Dalen Products, Inc., 11110 Gilbert Drive, Knoxville, Tennessee 37932, USA) net with a 5/8 X 3/4 inch (1.58 X 1.91 cm) mesh size costs approximately US $30.00 and provides enough material to make ca. 45 "mist nets." The polypropylene material lasts over repeated field use, thus adding to its cost efficiency.

We cut the netting into 1.5 X 1.0 m sections and folded it twice to triple the netting's thickness; the net now measured 1.5 X 0.3 m. The netting was suspended between two wooden poles (1.5 cm diameter, 100 cm length) and placed in the stream, river, or lake perpendicular to the shore line (Figs. 1a and 1b); half of the netting was submerged. Snakes that commonly swim along the stream or river bank (a natural drift fence) swim into the netting and become entangled. Snakes may be released from the netting by untangling or cutting the snake free. Freeing venomous snakes (e.g., *Agkistrodon piscivorous*) takes longer and can become tedious.

An enclosure (Figs. 1c and 1d) can also be constructed and baited with frogs, minnows, or other fish (e.g., centrarchids). Bait placed between the overlapped layers of netting will not sink or wash away. We found baited enclosures (also placed perpendicular to the stream bank) to have greater trapping success than single nets.

We used this trapping technique on seven sampling nights and at five different localities. We collected 13 snakes representing three species (*Nerodia rhombifer*, *Nerodia erythrogaster*, *Agkistrodon piscivorous*) during 20 trap-nights for an overall trapping success of 65% (Table 1).

This netting technique provides an additional and alternative method for sampling semi-aquatic snakes and offers a few advantages. First, the netting is easy to transport because it can be folded and bound with rubber-bands; 20–30 nets will easily fit in a nap-sack. While wooden poles offer some difficulty, transport is still considerably easier than funnel or minnow traps. Although funnel and/or minnow traps have provided much success in snake trapping (e.g., Fitch 1951, 1987; Keck 1994), funnel traps are bulky due to their construction from hardware cloth, and commercial minnow traps (although more portable) are expensive. Due to the circular design and diameter (19 cm) of minnow traps, snakes may only encounter a limited trap-area. Snake nets extended 1.5 m from the shoreline, thus increasing the trap area and the probability of a snake encountering the trap.

This new trapping technique is not without a disadvantage. Due to the netting's mesh size, this technique may be limited to catching larger snakes, just as minnow traps are limited to catching smaller snakes due to the size of their entrance hole (3–4 cm). Mean body mass and SVL for nine of the snakes we captured in

TABLE 1. Locality, date, trapping success, and species caught for each of the seven sampling nights. All localities are in Oklahoma, USA.

Sample	Locality (Date)	Number of Snakes	% Trapping Success	Species
1	Stream, Cleveland Co. (5/94)	7 (4 traps)	175	*N. rhombifer*
2	Farm Pond, Marshall Co. (7/94)	0 (2 traps)	0	
3	Farm Pond, Marshall Co. (7/94)	0 (3 traps)	0	
4	Fobb Bottom, Marshall Co. (8/95)	2 (3 traps)	66	*N. rhombifer* *N. erythrogaster*
5	Fobb Bottom, Marshall Co. (8/95)	1 (4 traps)	25	*N. rhombifer*
6	Cucumber Creek, Eagle Fork, LaFlore Co. (9/95)	3 (2 traps)	150	*A. piscivorous*
7	Cucumber Creek, beaver pond, LaFlore Co. (9/95)	0 (2 traps)	0	

Total trap-nights = 20. Total number of snakes captured = 13. Total trapping success = 65%.

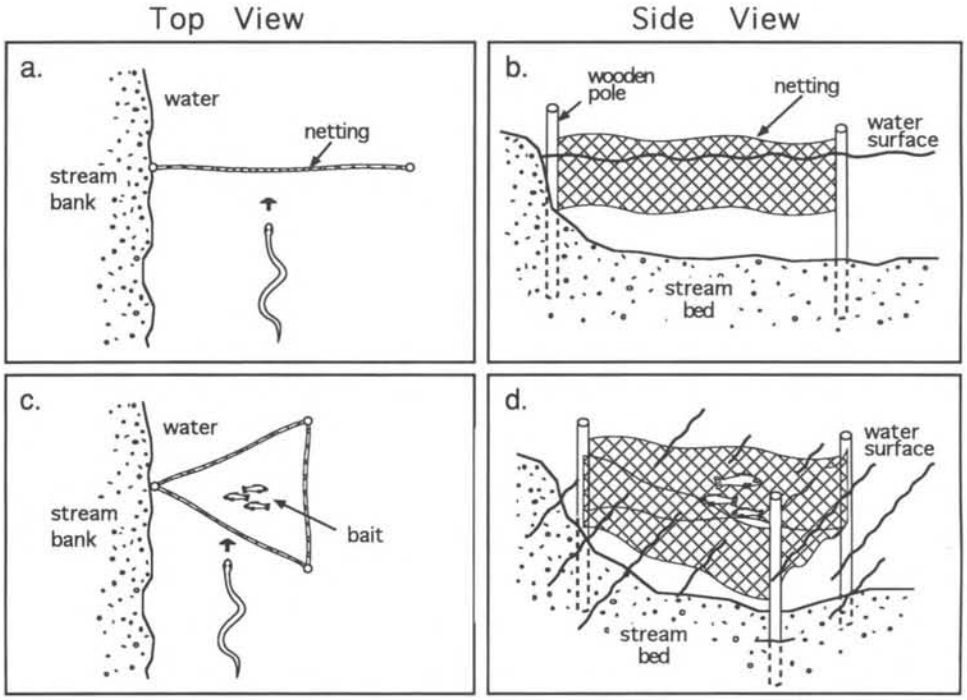

FIG. 1. Top and side views of the single snake net (a and b) and of the snake net enclosure (c and d).

snake nets were 391.4 g (SE = 52.42) and 69.0 cm (SE = 23.01), respectively. Juveniles and smaller semi-aquatic snake species may not be sampled with the netting we used. However, this technique may still prove valuable for the collection of smaller snakes upon finding netting with appropriate mesh hole size. When sampling snakes for census work, we suggest using several trapping and collecting techniques to include all size classes. One of these techniques may include snake netting.

Acknowledgments.—We thank Philip W. Lienesch for field assistance and Coral McCallister-Blanchard for help with figure illustration. We also thank Richard D. Durtsche, Victor H. Hutchison, Philip W. Lienesch, and Glenn A. Marvin for comments and suggestions regarding this manuscript.

Molecular analyses utilizing genomic DNA have revolutionized studies of systematics, ecology, evolution, and population genetics. Identification of restriction fragment length polymorphisms, DNA sequence disparities, and DNA fingerprints have been used to distinguish among individuals, populations, species, and higher taxa (e.g., Burke and Bruford 1987, Densmore et al. 1994, Parker and Whiteman 1993, and Vladychenskaya et al. 1993). While these techniques have proven extremely useful, sample collection often involves invasive techniques such as collection of blood by cardiac puncture (Sooter 1955; Dessauer 1970; Branch 1973; Cooper and Jackson 1981) or from the caudal vein (Reinert and Bushar 1991). In some cases it is necessary to sacrifice animals to obtain tissue for these analyses, and none of these approaches is ideal for working with neonates or endangered species. Shed snake skins provide a safe, non-invasive source of DNA.

While techniques for isolating DNA from skin samples have been described in the past (Knight et al. 1992), those utilizing proteinase digestion suffer from the long digestion period, as well as the possible degradation of the DNA which could occur during long incubations at elevated temperatures. Here we describe a modification of the protocol of Boom et al. (1990) which allows for the purification from shed skins of genomic DNA suitable for molecular analysis. The entire procedure can be completed in less than 3 hours and without an extended incubation period.

Shed skins from the timber rattlesnake, *Crotalus horridus*, and the corn snake, *Elaphe guttata*, were collected and stored at -20°C or -80°C prior to DNA purification. A 0.25 g sample is quick frozen on dry ice, transferred to a food processor (e.g., Black and Decker Handy Chopper HC20 type 3) containing 2 to 3 g of crushed dry ice, and processed by repeated ten-second bursts until skin and dry ice are reduced to powder. The powdered skin is then transferred to a loosely capped tube and repeatedly heated at 65°C for 3–5 minutes and mixed for 5–10 seconds until the color turns from grayish- to brownish-black, indicating that the CO_2 has sublimed. This step prevents the production of carbonic acid which could result in hydrogen cyanide gas formation during incubation of the homogenate in L6 buffer (see below).

The cell homogenate is then incubated in 3 ml of L6 buffer (Boom et al. 1990) for 30 minutes at 37°C, followed by centrifugation at 3000 X g for 5 minutes at room temperature (~20°C) to remove insoluble materials. In cases in which the homogenate is excessively viscous, 1.5 ml of TE, pH 8.0, may be added to the sample prior to centrifugation, and the centrifugation time increased to 10 minutes. L6 buffer is made by combining 120 g guanidine thyocyanate (Sigma Chemical Co.) in 100 ml 0.1 M Tris-HCl, pH 6.4 (heated to 65°C, shaking until dissolved), and then adding 22 ml 0.2 M EDTA, pH 8.0 and 2.6 g Triton X-100 (Sigma Chemical Co.). The buffer should be prepared in a fume hood and all wastes collected in 10 N NaOH to prevent hydrogen cyanide generation.

Following centrifugation, the supernatant is transferred to a clean, sterile tube; the volume of the supernatant is increased to 3 ml with TE buffer (10 mM Tris-HCl [pH 8.0]; 1 mM EDTA). Three ml of phenol: chloroform: isoamyl alcohol (49.5:49.5:1) is added to the supernatant and the resulting suspension is mixed on a rocking platform for 5 minutes. After mixing, the suspension is centrifuged at 3000 X g for 5 minutes at room temperature (~20°C). The supernatant is then transferred to a clean, sterile tube. The supernatant is subjected to a second extraction by the addition of an equal volume of chloroform:isoamyl alcohol (24:1) followed by mixing and centrifugation as described above. The resulting supernatant is transferred to a clean, sterile tube.

The DNA is then precipitated by the addition of 2 volumes of ice-cold ethanol, cooled for 10 minutes on dry ice (or at least 30 minutes at -20°C), and pelleted by centrifugation at 3000 X g for 15 minutes at room temperature (~20°C). The DNA pellet is then air dried for 10 minutes at room temperature (~20°C) and dissolved in 500 µl TE, pH 8.0. The DNA is re-precipitated by the addition of 50 µl of 5M NaCl followed by 1 ml of ice-cold ethanol, mixed by inverting several times, and cooled for 10 minutes on dry ice (or at least 30 minutes at -20°C). The DNA is pelleted by centrifugation at room temperature (~20°C) in a microcentrifuge for ten minutes. The DNA pellet is air dried for 10 minutes at room temperature (~20°C) and then dissolved in 100 µl H_2O.

We have successfully used this protocol to purify DNA from 31 shed skins representing 3 adult and 28 neonate *C. horridus* and 2 adult *E. guttata*. DNA concentrations and purities were measured by spectrophotometry; A_{260}/A_{280} ratios of 1.95 were obtained for DNA extracted from shed skin, with up to 100 µg of DNA obtained from 0.25 g aliquots of shed skin. Purity and quality of DNA isolated from shed skins was sufficient for amplification of microsatellite loci in *C. horridus* using the polymerase chain reaction (Villarreal et al., *in press*). This technique provides a useful alternative to traditional methods used to purify DNA for molecular analysis.

Acknowledgments.—We thank A. Knight and M. Culver for helpful discussion and M. Ortega-Nanos for technical assistance. This work was supported by a grant from the Pennsylvania Wild Resource Conservation Fund in cooperation with the Pennsylvania Fish and Boat Commission.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in volume 27, number 2 (June 1996).

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). **COMMUNAL NESTING.** Communal nesting by marbled salamanders is infrequent and typically includes fewer than three females. Of 72 nests observed by Graham (1971. Ph.D. Diss., Rutgers Univ.), only nine (12.5%) were communal and included the clutches of two (N = 7), three (N = 1), and seven (N = 1) females; 16 (5.5%) of 292 nests observed by Petranka (1990. J. Herpetol. 24:229–234) contained eggs of two females and three (1.0%) contained eggs of three females.

I observed communal nesting by marbled salamanders on 6 and 12 October 1995 at a semi-permanent, 15 x 19 m, man-made pond in the Hoosier National Forest, Crawford County, Indiana, USA. The pond is within a second-growth pine-hardwood forest. Approximately 15% of the clay-mud base is sparsely covered with herbaceous vegetation; the remainder is bare mud sparsely covered with fallen leaves. When these observations were made, half the basin was covered with water, leaving a 2 m wide band of mud above the water level. Nests were considered communal if clutches in adjacent depressions constructed by females were indistinguishable, the number of eggs was two or more times greater than the average of single nests (mean = 110 eggs), or nests contained eggs in varying stages of development.

Of 29 nests found, 12 (41.4%) were single-female nests containing 51–169 eggs, nine (31.0%) contained 163–319 eggs of two females, four (13.8%) contained 323–413 eggs of three females, one (3.4%) contained 514 eggs of four females, two (6.9%) contained 771 and 796 eggs of seven females, and one (3.4%) contained 1813 eggs of 16 females.

Marbled salamanders typically nest beneath cover such as leaf litter, logs, roots, rocks, or vegetation (Graham, *op. cit.*; Jackson et al. 1989. Can J. Zool. 67:2277–2281; Noble and Brady 1933. Zoologica 11:89–132; Petranka, *op. cit.),* or in crayfish or small mammal tunnels (King 1935. Ohio J. Sci. 35:4–15). Nests are generally concentrated in areas with high total cover (Jackson et al., *op. cit.).* The Crawford County pond is devoid of accumulated leaf litter from previous years except at the basin edge. Only four nests were found in this zone, the remainder were located at middle or lower elevations where leaf litter was absent when females oviposited. Females may have been forced to nest communally due to the paucity of cover. Most nests were partially or completely exposed until covered with freshly fallen leaves. Although females may have oviposited simultaneously in some nests, embryos in several communal nests ranged from Harrison stage 19 to 37 (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York, pp. 131–132), suggesting that later arriving females may have used eggs of preceding females as cover.

Only three nests (10%), all communal, had a single female in attendance. Nest attendance, which increases embryo survival, is typically much higher than that observed at the Crawford County pond (e.g., 87.4%, Jackson et al., *op. cit.;* 75.5%, Petranka, *op. cit.).* Estimates of embryo mortality in five communal nests ranged from 0–90%. The largest communal nest was exposed to direct sunlight for one hour each morning. On 12 October, temperatures in this nest varied from 22°C at the bottom to 27°C at the top immediately after exposure to the sun, suggesting that high temperatures may have contributed to high (ca. 90%) embryo mortality (Anderson 1972. Herpetologica 28:126–130).

I thank J. Sean Doody for commenting on the manuscript.

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). **COLORATION.** A mottled *Amphiuma tridactylum* was brought to Northeast Louisiana University Museum of Zoology by an anonymous person during summer 1988. The specimen (NLU 70638) measured 34 cm SVL, pigmentation varied from dark brown to black circular blotches of assorted sizes with a leucistic body color (Fig. 1). The origin of the specimen is unknown, however it is believed to have been collected in Louisiana.

FIG. 1. Adult mottled (left) and albino (right) *Amphiuma tridactylum* from Louisiana.

A second specimen, an albino, was collected 20 July 1992 in a ditch approximately 8 rd km S of Thibodaux, in Lafourche Parish, Louisiana, USA, by Terry P. Guidroz. This specimen (NLU 70488), 243 cm SVL, lacks all pigmentation except for the coloration of its blood vessels and pink eyes (Fig. 1).

then mixed with the stomach contents by gently massaging the belly; contents are removed by inverting the animal, retracting the tube an additional 2–3 cm (estimated distance from the hind wall of the stomach to the distal end of the sternum), and applying gentle pressure from the rear to the front of the stomach. The stomach contents are then collected in a plastic container; food becoming lodged in the mouth or pharynx is easily removed with forceps. This procedure is repeated 3–6 times for each animal and is stopped when the expelled water contains no plant items.

To test the efficiency of this procedure, one yearling and 13 hatchling iguanas were sacrificed, and the remaining stomach contents were analyzed after the procedure had been used. An average of 83.2%of all stomach contents (range 32–100 %) was recovered, and all species present in the stomach were detected in 13 of 14 cases. We did not consider it necessary to sacrifice larger animals to test the efficiency of the method.

Using this technique, we have been able to recover remains of 125 species of plants (Molina 1991; Rivas 1990). Stomach washing was performed on 365 iguanas ranging in size from hatchling (70 mm SVL, 12 g) to adult (up to 450 mm SVL, 4500 g). No animals died during the treatment although, in early attempts, some animals appeared weak after the maneuver. Many iguanas previously "stomach-washed" were recaptured in subsequent years and showed no ill effects.

This method provides a safe and easy way to study the dietary habits of large lizards. Because water is poured into the tube, no water pressure is applied to the animal gut, and no pump or syringe is needed. Although we used this method only for green iguanas, we believe it could be used with other lizards of comparable size; it was also used successfully with hatchling spectacled caiman (*Caiman crocodilus*) (Escalona, pers. comm.).

Acknowledgments.—We thank Thomás Blohm for the use of his ranch facilities, and the Wildlife Conservation Society (WCS) for financial support. Carlos Coronel allowed us to sacrifice some iguanas at his ranch. Gustavo Hernandez provided useful comments on the application of the technique. P. T. Andreadis, G. M. Burghardt, D. Truett, A. S. Rand, J. Thorbjarnarson, and A. E. Echternacht also provided useful comments and editorial suggestions.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send three copies of manuscripts, double-spaced, directly to the appropriate section coeditor (addresses on inside front cover): Lee A. Fitzgerald (lizards, amphisbaenians, crocodilians, Sphenodontia); Charles W. Painter (amphibians); or Paul A. Stone (snakes, turtles). Authors are encouraged to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a text-only version of the file.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins (1990. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 3rd ed., Herp. Circ. 19:1–41; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113). KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

ANURA

LITORIA FALLAX (Eastern Dwarf Treefrog). **REPRODUCTION.** McCoid (1993. Herpetol. Rev. 24:16–17) reported this introduced species as occurring island-wide on Guam, Mariana Islands, in association with wetlands. In the native range, neither Cogger (1988. Reptiles and Amphibians of Australia, 5th ed., Reed Books, Pty. Ltd., NSW, 688 pp.) nor Frith and Frith (1987. Australian Tropical Reptiles and Frogs, Tropical Australia Graphics, Queensland, 70 pp.) mentioned reproductive periodicity. Although calling males have been heard year-round on Guam after heavy showers, successful reproduction during the dry season (December–May) may be tied to episodic rainfall. Successful reproduction is probably seasonal in ephemeral bodies of water as tadpoles and froglets have only been observed during the rainy season. On Guam, many wetlands are ephemeral and tend to contract or disappear during the dry season.

Size at maturity is ca. 30 mm SVL and at metamorphosis, froglets are 11–13 mm SVL. At metamorphosis, froglets are brown dorsally, but turn green at they grow. Maximum known size on Guam is ca. 40 mm SVL.

Michael Ritter aided in field work and Rebecca Hensley reviewed a version of this manuscript. Portions of this study were supported by the Endangered Species Conservation Program, Project E4 (to Guam).

Submitted by **MICHAEL JAMES MCCOID**, Division of Aquatic and Wildlife Resources, P.O. Box 2950, Agana, Guam 96910, USA. Current Address: Caesar Kleberg Wildlife Research Institute, Campus Box 218, Texas A&M University, Kingsville, Texas 78363, USA.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). **MAXIMUM SIZE.** Maximum body size for *O. septentrionalis* is 140.0 mm SVL (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern North America, 3rd ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). This maximum figure is cited from a previous record (Wright and Wright 1949. Handbook of Frogs and Toads of the United States and Canada, Comstock Publ. Assoc., Ithaca, New York. 640 pp.). However, the 140.0 mm SVL record of Wright and Wright (*op. cit.*) is not present in their series of specimens and they "recall none over 4 inches" (101.6 mm SVL). Wright and Wright (*op. cit.*) state that the maximum length of 5.5 inches SVL (printed as 130.0 mm instead of 139.7 mm) is an approximation for females which they made from their series. I have been unable to find records approaching this size in the literature. Consequently, the status of maximum size in this species has been unclear. Here, I present the maximum size record for *O. septentrionalis*. In June 1993, an individual was captured on a hotel in Sebring, Highlands Co., Florida, USA and sold to a local petshop. I purchased the frog from the petshop within one week of its arrival, at which time it measured 155.0 mm SVL. A visit with hotel employees corroborated the story of its origin. It was kept in captivity and fed mice, other treefrogs, conspecifics, roaches, and anoles, until it died on 24 October 1994. At the time of death, it was determined to be a female and measured 165.0 mm SVL. After one week in 10% formalin, it measured 155.0 mm SVL and was deposited as USNM 337559. Large female *O. septentrionalis* are not rare; I have examined females ≥100.0 mm across its geographic range. However, because clutch and egg size increase with an increase in body size in this species (Meshaka 1994. Unpubl. Ph.D. dissertation, Florida International Univ., Miami), gigantic females can greatly contribute to the colonization process as founders of new colonies such as at Sebring where the colony is unlikely to be older than five years.

Males are smaller than females in this species (Duellman and Schwartz 1958. Bull. Florida State Mus. 3:181–324; Meshaka, *op. cit.*) and are mature at 27.0 mm SVL (Meshaka, *op. cit.*). The maximum body size of males is reported to be 112.0 mm SVL from a skeleton of an individual that originated from Key West (Mittleman 1950. Herpetologica 6:20–24) but it lacks verification (Duellman and Crombie 1970. Cat. Amer. Amphib. Rept. 92.1–92.4; R. Crombie, pers. comm.). Records of 89.0 mm SVL (Conant 1975. A Field Guide to Reptiles and Amphibians of Eastern North America, 2nd ed., Houghton Mifflin Co., Boston, Massachusetts. 429 pp.) and 90.0 mm SVL (Conant and Collins, *op. cit.*) approximate the 3.5 inches SVL (88.9 mm) presented in both field guides (J. T. Collins, pers. comm.) and are similar to a preserved male of 88.5 mm SVL (Mittleman, *op. cit.*). Records of large males are noteworthy because of their rarity. From >1500 males I examined from Florida and the West Indies, only two individuals exceed 75.0 mm SVL. The first (85.0 mm SVL in 10% formalin) was collected on 16 July 1993 from a house in Lake Placid, Highlands Co., Florida, USA (USNMFS 217671). The second (83.0 mm SVL) was collected in January 1967 in Tabajo, Baracoa, Guantanamo, Cuba (no other data), and stored in the museum of Instituto de Ecologia y Systematica de Academia de Sciencia de Cuba, La Chata, Ciudad de Havana, Cuba. If the well-developed sexual dimorphism in body size is enforced in the ecology of males, then only unusual conditions would produce large males in the wild. In this regard, Mittleman's (*op. cit.*) 112 mm SVL record is at least plausible, even if exceedingly rare. I thank Luis Moreno, curator of reptiles and amphibians at La Chata, for kindly allowing me to examine specimens in June 1994.

Submitted by **WALTER E. MESHAKA, JR.**, Museum, Everglades National Park, 40001 SR-9336, Homestead, Florida 33034-6733, USA.

RANA CATESBEIANA (Bullfrog). **RECORD SIZE.** The largest *Rana catesbeiana* reported is 20.3 cm SVL (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston, Massachusetts. 450 pp.); the Oklahoma record is 17.8 cm (Black and Sievert 1991. A Field Guide to Amphibians of Oklahoma, Oklahoma Dept. Wildl. Cons., Oklahoma City). Here we report a new Oklahoma and North American record SVL for *R. catesbeiana*.

The female bullfrog was found by John Lake on 3 May 1995 along Bishop Creek in Norman, Cleveland Co., Oklahoma, USA (T9N, R2W, NE1/4 of SW1/4 Sec 32). Body mass and mean SVL were 908.6 g and 20.42 cm (SE = 0.06, N = 4). The SVL was measured from the tip of the snout to the posterior edge of the vent with the frog placed on its back. The mean SVL was determined from independent measurements by four herpetologists. This reduced possible biases in individual measuring techniques and provided a measure of dispersion (standard error) for SVL. All measurements were made to the nearest millimeter with large calipers.

FIG. 1. Record-sized *Rana catesbeiana* from Cleveland Co., Oklahoma.

Body size >20 cm SVL in *R. catesbeiana* is rare. The largest of 2000 bullfrogs from an introduced population in southeastern Arizona measured 20.1 cm SVL and ca. 800 g (C. Schwalbe, pers. comm.). Such body size in natural populations may be more rare. Lance Fontenot (pers. comm.) sampled bullfrog populations from Louisiana and South Carolina and found maximum SVL of 18.1 (N = 70) and 15.9 (N = 79) cm, respectively. Howard (1981. Ecology 62:303–310) measured 283 bullfrogs in Michigan over a four-year period and observed a maximum SVL of 17.2 cm. A study in Missouri (where bullfrogs may be morphologically more similar to Oklahoma populations than those from Michigan) showed a maximum SVL <18.0 cm for 288 individuals (Moyle 1952. M.S. Thesis, University of Missouri, Columbia).

The frog is being maintained on live exhibit; upon death the specimen and a photograph (Fig. 1) will be deposited in the her-

petological collection of the Oklahoma Museum of Natural History (OMNH, collector's number VHH-95-001).

We thank Katie Meier and Dick Durtsche for their measurements of SVL, Coral McCallister-Blanchard for photo processing, and John Lake for donating the specimen to the University of Oklahoma.

Submitted by **WILLIAM I. LUTTERSCHMIDT, GLENN A. MARVIN**, and **VICTOR H. HUTCHISON**, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, USA.

RANA CATESBEIANA (Bullfrog). **PREDATION.** The diet of *Dolomedes triton*, the six-spotted fishing spider, includes many insects and small fish (Carico 1973. Bull. Comp. Zool. 144(7):435–488), but the inclusion of *Rana* tadpoles in the diet of these spiders has not been widely documented. Of 625 prey items identified by Zimmermann and Spence (1989. Oecologia 80:187–194) only one was an amphibian (female spider, *Rana sylvatica* tadpole). In lab studies (Bleckmann and Lotz 1987. Anim. Behav. 35:641–651), *D. triton* was observed capturing *Bufo bufo* tadpoles and juvenile *Xenopus laevis* (2–3 cm SVL).

On 24 May 1994, between 2100 and 2230 h, a gravid female *D. triton* was captured in the process of feeding on a *R. catesbeiana* tadpole at a small farm pond 3 mi. S. of Jacksonville, and 1 mi. E. of AL Hwy 21 on Longshore Drive, Calhoun Co., Alabama, USA. The spider was hanging from a partially submerged metal structure by the hindmost pair of legs, while grasping the tadpole at the water's surface with the two anterior pairs of legs. The tadpole was ca. 60 mm TL. The tadpole had well developed hind legs but no visible forelimbs. The cephalic region of the tadpole was necrotic, presumably indicating the point of attack.

Because *D. triton* feeds on small fish and insects it seems logical that it would also include tadpoles as part of its diet. The importance of tadpoles to the diet of *D. triton* is not known. The only records of *D. triton* predation on ranids have been by females which may indicate that due to sexual size dimorphism only females are large enough to include *Rana* tadpoles in their diet.

Submitted by **C. PAUL ROGERS**, Department of Biology, Jacksonville State University, Jacksonville, Alabama 36265-9982, USA.

RANA PRETIOSA (Spotted Frog). **PREDATION.** The distribution and abundance of *Rana pretiosa* have declined sufficiently throughout the southern extent of its range to warrant listing under the U.S. Endangered Species Act as a Candidate 1 species (Fed. Reg. 1994). Most remaining populations of *R. pretiosa* in the southern portion of its range (e.g., the Great Basin) are small and isolated. Therefore predation, although a natural factor and unlikely to have induced the observed declines, could be a serious threat to the persistence of this species in the region. This note documents predation on *R. pretiosa* by the wandering garter snake, *Thamnophis elegans vagrans*.

More than 100 h of observations of *R. pretiosa* behavior were made between 21 June and 10 August 1994 at a 400 m early seral stage meadow/spring complex consisting of 17 distinct pools along a permanent creek in the Toiyabe National Forest, Nye Co., Nevada, USA. The pools ranged in length from 3.1–22.8 m, width from 1.2–3.3 m, and depth from 0.1–0.6 m. The pools were 60–90% covered in rooted vegetation (e.g., *Potamogeton foliosis* and *Ranunculus aquaticus*) and contained dense populations of native fish (e.g., *Rhinichthys osculus* and *Catostomus tahoensis*). Cattle moved through the site, grazing heavily for a period of less than one week during the observation period. *Rana pretiosa* density (3.4 frogs/m^2) at this site is the greatest known in Nevada. The density of *T. e. vagrans* was estimated at 0.2 snakes/m^2. Snakes (19.5–51.0 cm SVL, 26.1–69.3 cm TL) were always present at the site during diurnal visits and appeared to be hunting consistently. On 21 June 1994 at 0745 h, JKR observed a *T. e. vagrans*, ca. 65 cm TL, in the process of consuming a *R. pretiosa*, ca. 5.0 cm SVL. The frog was totally consumed in five minutes and the snake seemed little alarmed by human presence. On 26 July 1994 at 0900 h (air 30°C, water 13°C) we found a dying male frog (5.0 cm SVL, 9.5 g) spread out on floating vegetation at the edge of a pool. The frog's right rear leg was dislocated and had multiple fractures. The frog died within moments of observation. The conjecture that injury was caused by snake attack is supported by another observation, made at a different pool later that same morning. At 1147 h (air 35°C, water 15°C) we observed the tail of a submerged snake twisting and thrashing through vegetation at the water surface. Close examination revealed that the snake had a medium-sized frog by one rear leg and was rapidly spinning itself and the frog. Unfortunately, the snake was startled and released the frog. Both were caught and measured. The snake measured 27 cm SVL, 38 cm TL, 16 g; and the frog, a male, measured 4.0 cm SVL, 7.5 g.

Several other potential predators of frogs (e.g., common raven, black-crowned night heron, badger, and coyote) occurred at, or were observed within range of, the site but were never seen hunting frogs either during diurnal or nocturnal observation periods. The absence of introduced trout at this site may be a significant factor in the frog population's persistence; historical frog locations in nearby drainages now stocked with fish apparently support few or no frogs.

A three-year study of *R. pretiosa* in progress at this site indicates that mortality of young individuals is high (RED and JKR, in prep.). Based on our observations, snake predation is likely the most significant cause of natural mortality, both directly through consumption and indirectly through attack-invoked injury. Because the frog population at this site is likely the source for subpopulations under favorable dispersal conditions and is one of very few sources for individuals if regional reintroduction programs are established, high mortality deserves special concern, even if the causative agents are natural.

Funding for studies of the spotted frog in Nevada was provided to JKR through a Stanford University Department of Biological Sciences Graduate Research Fellowship and to RED through Stanford University Undergraduate Research Opportunities. We thank the Toiyabe National Forest for permitting research at this site and the Nevada Biodiversity Initiative for logistical support. We are grateful to Alan E. Launer for commenting on the manuscript.

CAUDATA

EURYCEA CIRRIGERA (Southern Two-lined Salamander). **NEST SITE.** *Eurycea cirrigera* prefers to attach its eggs to the undersurface of submerged rocks, logs, and aquatic plants (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama, 347 pp.) in fast flowing wa-

ter (Martof et al. 1980. Amphibians and Reptiles of the Carolinas and Virginia. Univ. of North Carolina Press. Chapel Hill, 264 pp.). During April and May of 1995 in Poplar Cove Spring at the University of Mississippi Biological Field Station in Lafayette Co., Mississippi, USA, seven clutches of *E. cirrigera* eggs (mean = 53 eggs/clutch) were found, each with an attending female. Three of these clutches (mean = 67 eggs/clutch) were typically attached to the undersurface of a log in fast flowing (mean flow rate = 0.168 m/sec), highly oxygenated (approximately 8.0 ppm 0_2) water at 15°C. In contrast, the other four clutches (mean = 43 eggs/clutch) were found buried and unattached to a substrate in detrital sediment of low oxygen concentration (approximately 3.0 ppm 0_2). These latter clutches were buried just below the sediment surface under ca. 0.02 m of slow flowing (mean flow rate = 0.024 m/sec) water at 18°C. This nest site location and lack of ova attachment is atypical for this species. The distinct differences in nest site selection among females at this site may reflect alternative reproductive strategies, which may result in developmental and life history traits not previously considered for this species.

I thank R. Austin, R. Holberton, F. Zaidan (Univ. of Mississippi), and S. Marshall for their assistance in preparing this note.

TESTUDINES

CARETTA CARETTA (Loggerhead Sea Turtle). **NESTING FREQUENCY**. For loggerhead sea turtles, a record number of seven nests in one season has been observed twice in Georgia (Lenarz et al. 1981. Herpetol. Rev. 12:9; J. I. Richardson, pers. comm.). These events occurred in 1979 and 1990.

On both the east and west coasts of Florida, USA, the most nests reported for a loggerhead during a nesting season has been six (Dodd 1988. Synopsis of the Biological Data on the Loggerhead Sea Turtle *Caretta caretta* (Linnaeus 1758). U.S. Fish and Wild. Serv. Biol. Rept. 88(4) 110 pp.; LeBuff 1990. The Loggerhead Sea Turtle in the Eastern Gulf of Mexico. Caretta Res., Inc. Sanibel, Florida. 216 pp.). On Key Island, located south of Naples, on Florida's southwest coast, seven nests were documented for two individual turtles (tagged PPV921 and QQN240) in 1991 and 1992 (Table 1).

From 1985 to 1994, 207 multiple nesting loggerheads were observed on Key Island. Internesting periods of 10 and 11 days were the most frequently recorded intervals. Of the 472 internesting intervals recorded (range = 9–70 days), 36% were 10 or 11 days. Most longer intervals are probably due to the fact that only 5.9 km of the entire 12 km length of the island is patrolled nightly. Consequently, many turtles with internesting intervals between 18 and 70 days (N = 151) may not have been seen when they returned to nest on this beach or an adjacent one. Hence, the actual percentage of 10 and 11 day intervals is probably higher than 36%.

As 10 and 11 day intervals occur frequently, it is possible that PPV921 may have nested eight times in 1991. Similarly, QQE490 and QQE502 may have nested seven times (Table 1). QQE502's last observed nesting was on 17 July, a month prior to the end of the nesting season on this coast. Although only two nests were recorded for PPJ735 and PPJ780, the intervals between nests were within the 74–66 day range of the other turtles which were observed or suspected to have nested seven times. Thus, these turtles could have nested other times without our knowledge.

This report documents seven nests in a season by loggerhead sea turtles on the southwest coast of Florida. The data also suggest that, while seven nests in one season by loggerheads is certainly not a common event, such occurrences may be more frequent than existing records indicate.

TABLE 1. Nesting intervals and dates for Key Island loggerheads.

Tag no.	First nest	Intervals	Last nest	Days	Nests
PPV921	20 May 1991	13,12,10,9,9,21	2 Aug	74	7
QQN240	15 May 1992	14,12,11,11,9,11	22 July	68	7
QQE490	16 May 1991	14,12,21,9,10	21 July	66	6
QQE502	22 May 1994	13,11,10,10,12	17 July	57	6
QQE531	23 May 1991	12,22,20,14	29 July	68	5
PPJ735	16 May 1992	70	31 July	70	2
PPJ780	26 May 1992	66	31 July	66	2

I thank my predecessor, Ron Mezich, for keeping accurate records in the early years and to approximately 40 interns whose efforts over the years have made the Key Island monitoring project possible. I also appreciate James I. Richardson's advice and comments.

HYDROMEDUSA MAXIMILIANI (Maximilian's Snake-necked Turtle). **EPIZOIC COMMENSAL.** Two specimens of the South American chelid turtle *Hydromedusa maximiliani* in the collection of the United States National Museum of Natural History (USNM) were found to have clusters of temnocephalid turbellarian worms (Platyhelminthes: Turbellaria: Temnocephalida) and their encapsulated eggs attached to their shells. The first specimen (USNM 208284), collected 29 December 1977 at Reserva Biologica Nova Lombardia near Santa Teresa, Espirito Santo State, Brazil by Ronald I. Crombie, Maria C. Duchene, W. Ronald Heyer, and Francisca C. do Val, had clusters of encapsulated eggs attached to the anterior surface of the right bridge and the underside of the adjacent fifth marginal and on both femoral scutes. The second specimen (USNM 208681), collected 13 December 1977 2 km NE of Alto do Soberbo near Teresopolis, Rio de Janeiro State, Brazil by Crombie, Duchene, and Heyer, had adult worms attached to both bridges and dense clusters of eggs widely distributed on all posterior plastron scutes. Absence of worms on the dorsal surface of the carapace may be possibly explained by the species' habits of basking and traveling overland. Both turtles were taken from streams in primary forest between 1930 and 2200 h.

Temnocephalids compose an order of tropical and subtropical, freshwater, ectocommensal or parasitic, tentacled, flatworms that usually encapsulate on the exoskeletons of crustaceans or the shells of mollusks, but have been occasionally found attached to the shells of turtles (Barnes 1987. Invertebrate Zoology, 5th ed., Saunders College Publ., Philadelphia, Pennsylvania, 893 pp.). *Temnocephala brevicornis* has been previously found on a South American snake-necked turtle, *Hydromedusa tectifera*, from Uruguay (Cordero 1946. Com. Zool. Mus. Hist. Nat. Montevideo

2[34]:1–12). The worms attached to the two *H. maximiliani* also appear to be *T. brevicornis*, representing a new host record for the worm. The only other epizoic commensal reported from this turtle genus was the barnacle *Balanus improvisus* from an Argentine *H. tectifera* (Frazier 1986. Proc. Biol. Soc. Washington 99:472–477).

We thank Ronald I. Crombie for calling our attention to the infested turtles, and W. Ronald Heyer for permission to examine them and his field notes.

MALACLEMYS TERRAPIN TERRAPIN (Northern Diamondback Terrapin). **REPRODUCTION** and **NEST PREDATION.** Information on clutch size and rate of nest predation of northern diamondback terrapins along the Connecticut and New York coasts of Long Island Sound has been limited to infrequent observations of small samples of isolated individuals. Klemens (1993. Amphibians and Reptiles of Connecticut and Adjacent Regions. State Geol. Nat. Hist. Surv. Connecticut Bull. 112:1–318) reported a diamondback terrapin collected from Fairfield, Connecticut, USA containing 12 eggs, a nest in Westport, Connecticut containing 13 eggs, three clutches in Rye, New York containing 8, 11, and 15 eggs, and eleven clutches from the Jamaica Bay Wildlife Refuge, New York with a mean clutch size of 14.9 eggs.

During a population study of *Malaclemys terrapin terrapin* in 1994, a relatively large nesting site was discovered adjacent to a tidal creek along the Neck River in Madison, Connecticut. The nests were concentrated in a flat, sandy area (30 x 100 m) approximately 10 m from the creek. Sparse vegetative cover consisted of several bayberry bushes (*Myrica pennsylvanica*), poison ivy (*Rhus radicans*), and beach grass (*Ammophila breviligulata*). The area was bordered by a large expanse of *Spartina* salt marsh. Ten female *M. t. terrapin* were captured and measured during the 1993–1994 nesting seasons [mean carapace length (SLC) = 183.1 mm; SD = 7.43, mean plastron length (SLP) = 164.6 mm; SD = 7.14]. Maximum nesting activity was observed at high tide during the early daylight hours of 1–5 July 1994. From 1–31 July 1994, 33 nests were located. Clutch sizes were determined by excavating nests and counting eggs, and counting shells from nests opened by predators. Clutches ranged from 4 to 16 eggs with a mean clutch size of 9.6 (N = 33; SD = 3.58). Predators destroyed the entire clutch in each of the 33 nests (316 eggs). Numerous footprints throughout the area and bite patterns in the egg shells suggested that raccoons (*Procyon lotor*) were the only predators. They exhumed all eggs from each nest, consumed the contents, and discarded the shells within a few centimeters of the nest hole, often in a neat pile.

The observed mean clutch size (mean = 9.6) of this Connecticut population is similar to the mean clutch size (mean = 9.2, N = 237) reported by Burger (1977. Am. Midl. Nat. 97: 444–464) in a two-year study of a population of *M. t. terrapin* along the southern coast of New Jersey. Clutch sizes have been reported to be slightly lower in the southern subspecies. Hildebrand (1932. Zoologica. 9:551–563) noted that the "usual number" of eggs laid at one time by *M. t. centrata* x *M. t. terrapin* in captivity was eight. Burns and Williams (1972. J. Herpetol. 6:238–239) found that captive *M. t. pileata* produced a mean clutch size of 8.5 (N = 11) in Louisiana. Seigel (1980. Trans. Kansas Acad. Sci. 83:239–246) reported a mean clutch size of 6.7 (N = 14) for a population of *M. t. tequesta* on the Atlantic coast of Florida. The present findings in Connecticut provide further evidence that the diamondback terrapin produces larger average clutch sizes in the northern part of its range.

Field work was performed by Matthew Aresco, Marcy Klattenberg, and Beth Lapin. This study was supported by a grant from the Phillips Petroleum Environmental Partnership (PEP).

PODOCNEMIS UNIFILIS (Yellow-headed Sideneck). **NESTING.** *Podocnemis unifilis* is a medium to large pelomedusid turtle widely distributed throughout the Orinoco and Amazon River basins in South America. The species is of considerable importance as human food during the dry season, with both eggs and turtles being consumed or sold in large quantities throughout the species' range (Johns 1987. Oryx 21:25–28; Mittermeier 1978. Oryx 14:222–230). Commonly referred to as the tracajá in Brazil, nests of this species have been widely reported as shallow holes dug in sandy or loamy substrates along rivers and streams (Foote 1978. Herpetologica 34:333–339; Thorbjarnarson et al. 1993. J. Herpetol. 27:344–347).

Tracajá are known to inhabit streams and lakes in flooded forest, or *várzea*, in the Brazilian Amazon, including in the Mamirauá Ecological Station (MES), Amazonas, Brazil, located 30 km upstream of the town of Tefé. The MES consists of extensive lake and marsh habitat interspersed with forest (low and high *restinga* forest) in a broad floodplain at the confluence of the Amazon (Solimoes) and Japura Rivers (Ayres 1993. As Matas de Várzea do Mamirauá. CNPq, Brasilia. 123 pp.). Tracajá are known to inhabit regions of extensive *várzea*, but were tacitly assumed to migrate into riverine habitats for nesting in sandy beach substrates.

On 28 September 1994, while searching for nests of black caiman (*Melanosuchus niger*), we located a nest of *P. unifilis* on a floating mat of vegetation and organic matter (Fig. 1) in a small lake (Lago Sanguesuga; S 02° 58.96', W 64° 55.57') within the MES. The nest was made in organic soil composed principally of partly decomposed leaves, in the elevated root mat of a fallen tree (*Symmeria paniculata*; Polygonaceae; "Carauaçu"). The water level of the lake had fallen so that the organic mat, which would float during periods of high water, was resting on the lake bottom. The nest was found approximately one month before the average annual minimum water level is attained at MES.

The nest cavity was 65 cm above the bottom of the organic mat, but 15 cm below the mat's highest point, and had been recently opened by a predator (probably *Tupinambis nigropunctatus*). Three eggs remained in the nest cavity, and the remains of 19 others were scattered up to 5 m from the nest. The mean size of the three entire eggs was: 3.83 cm (length), 3.04 cm (diam), and 20.9 g. All three eggs in the nest cavity were opaque on their upper halves, translucent below, suggesting that they had been laid within two weeks of our finding them. The nest cavity was 17 cm deep and 13 cm wide.

According to a local informant (Sr. Revolver, pers. comm.), it is not unusual for tracajá to nest in similar substrates within the *várzea*. However, the sympatric *P. sextuberculata* and *P. expansa* were reported to always nest in sandy beaches along rivers. *Peltocephalus dumerilianus*, which lay much larger eggs (Pritchard and Trebbau 1984. The Turtles of Venezuela. SSAR Contrib. Herpetol. 2:1–403), are also reported to use fallen tree root mats

as nesting sites in flooded forest habitats (Medem 1983. Lozania 41:1–12.).

We thank M. Ayres for providing us with the opportunity to work in the Mamirauá Ecological Station, and Sr. Revolver for his work as a guide and assistant. Funding for the work was provided by CNPq, the British Overseas Development Agency (ODA), WWF-England, and the Wildlife Conservation Society.

TERRAPENE CAROLINA CAROLINA (Eastern Box Turtle). **HABITAT.** On 3 September 1994 at Buckeye Creek Cave in Greenbrier Co., West Virginia, USA, we discovered an adult *Terrapene c. carolina* 75 m in from the cave entrance (measured from the large boulder just inside the cave). The turtle was observed on the edge of the cave stream, facing away from the stream with the posterior edge of the carapace and hind legs slightly submerged. We photographed the turtle to document its occurrence in the cave, but did not handle it or determine the sex. One photograph was deposited in the Ohio State University Museum of Biological Diversity Vertebrate Collections and another was sent to the West Virginia Department of Natural Resources. The turtle may have crawled, swam, or washed into the cave at the main entrance where the stream enters the cave and is shallow and cobble-strewn. A detailed description of Buckeye Creek Cave can be found in Dasher and Balfour (1994. West Virginia Speleological Survey Bulletin 12. 236 pp.).

Our account of *T. c. carolina* in Buckeye Creek Cave appears to be the first for this species, as well as for any turtle, in a West Virginia cave. Garton et al. (1993. West Virginia Speleological Survey Bulletin 11. 107 pp.) reported no occurrences for any turtles in West Virginia caves; however, Dearolf (1956. Proc. Pennsylvania Acad. Sci. 30:201–210) listed *T. c. carolina* from a Tennessee cave. Considering the lack of records for box turtles in caves and the time of year we made the observation, this box turtle occurrence should be considered accidental, but it does add *Terrapene c. carolina* to the Buckeye Creek Cave fauna.

We thank J. Condit for loaning us literature, G. Turner for kindly allowing us access to the cave, J. D. Williams and E. R. Garton for providing information about Buckeye Creek Cave, D. L. Claussen for providing a reprint concerning hibernation, and two anonymous reviewers for making helpful comments.

LACERTILIA

ANOLIS CAROLINENSIS CAROLINENSIS (Green Anole). **NECTAR FEEDING.** During the summer and fall of 1994 two different types of hummingbird feeders were maintained at my home. I noted that one of the feeders was frequented by green anoles which are common in my yard whereas the other was not, even though both were on an outdoor patio ca. 3 m apart with the same "nectar" used in both. Upon close, quiet observations the anoles were seen to drink the nectar. On three occasions the red nectar was observed on the jaws of the anoles. At least three different anoles frequented the feeder. The placement of the feeders was switched and the anoles switched with them inasmuch as both were easily accessible by the same routes. Feeder use by anoles corresponded to feeder shape: a flower-shaped feeder was frequented while a flat feeder with holes was avoided. Bartlett (1995. Reptiles 2(5):48–65) stated that though "the green anole is primarily an insectivorous species, it may lap at nectar, pollen and tree sap, and may even consume an occasional brightly colored flower petal." To my knowledge, nectar feeding by anoles from hummingbird feeders has not been reported.

Submitted by **ERNEST A. LINER,** 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA.

CHAMAELEO CHAMAELEON (Common Chameleon). **DIET.** The common chameleon is broadly distributed in the southern regions of the Mediterranean basin (Hoofien 1964. Israel J. Zool. 13(2):136–138; Pasteur and Bons 1960. Trav. Inst. Sci. cherif. 21:1–132; Werner 1971. Bull. Brit. Mus. (Nat. Hist.) 21(2):213–256), but it has been introduced in several other geographic regions, including Portugal, Canary Islands, Sicily, and Malta (Bruno 1986. Tartarughe e sauri d'Italia. Giunti editore, Milano, 255 pp.). On Malta Island the species was introduced some 100 years ago, and its scattered populations are endangered mainly because of unrestricted collection for the pet trade (Corbett 1989. Conserva-

tion of European Amphibians and Reptiles. Cristopher Helm, London, 274 pp.). Biological data on chameleon populations from Malta are lacking and this note provides information on the food habits of this introduced taxon.

Data were obtained from free-ranging specimens captured during two seven-day surveys in June 1994 and late August 1994. Additional information came from field observations (U. Agrimi, Istituto Superiore di Sanità, Rome) during August 1990 in the same area where our research was carried out. All observations were made in the vicinity of Sliema, one of the main towns of Malta Island. The study site was a dry and sunny grassy area with patches of stone and acacia bushes. The chameleons were relatively common, and often climbed about 1 m above the ground. To study their diet, we collected fecal pellets of chameleons held in small cages until defecation. We did not collect feces from the environment. Feces were examined under a dissecting microscope and prey items were identified to the lowest taxon possible.

Table 1 summarizes the dietary data obtained during this study. Feces from 34 chameleons (18 males, 12 females, and 4 young) were collected, while stomach contents of two males, one female, and one juvenile found killed by cars provided additional prey items. Therefore, data given here include prey from both feces and stomach contents. The great majority (87.9%) of the 58 prey items identified were arthropods. Orthoptera and Cicadidae were the most frequently consumed prey. Small individuals of these prey taxa were the only prey observed in young chameleons (specimens <60 mm SVL). Juveniles and subadults of the Maltese lizard *Podarcis filfolensis* were occasionally preyed on by adult chameleons (especially by males).

We thank Umberto Agrimi who provided us with very useful information about chameleons in his care and showed us the study area. An earlier draft of this manuscript was critically reviewed and improved by Massimo Capula and Lee A. Fitzgerald.

TABLE 1. Prey items consumed by *Chamaeleo chamaeleon* around Sliema, Malta Island. Data were obtained from analysis of fecal pellets from 34 individuals and dissection of stomachs from 4 specimens found dead in the field.

Prey Type	Number in feces	Number in stomachs

Submitted by **LUCA LUISELLI**, Department of Animal and Human Biology, The University "La Sapienza," via Alfonso Borelli 50, I-00161 Rome, Italy, and **LORENZO RUGIERO**, via Domenico Cimarosa 13, I-00198 Rome, Italy.

EUMECES FASCIATUS (Five-lined Skink). **ENTRAPMENT.** On 1 August 1994, we found a hatchling *E. fasciatus* (0.264 g; 2.4 cm SVL length; 3.7 cm TL) dangling from a spider's web on the US 70 bridge over 2nd Creek, Rowan County, North Carolina, USA. The web was triangular and measured 16 x 8 cm. The lizard was alive, but unable to escape. Silk was tightly wrapped around it preventing free movement even after the lizard was removed (Fig. 1). Approximately 1.0 cm of the lizard's tail was broken and was wrapped separately in the web. The lizard was emaciated and its belly was dark brown, probably due to overexposure to the sun. Our best guess was that it had been trapped in the web for no more than a day. A mature male spider (Theriididae: *Achaeranea*) with a body length (tip of abdomen to tip of cephalothorax) of 3 mm and leg length (Leg I) of 14 mm was found in the web about 2.0 cm from the hatchling.

Comb-footed and widow spiders (Family Theriididae) are known to prey on small lizards (Blondheim and Werner 1989. Brit. Herpetol. Soc. Bull. 30:26–28; McCormick and Polis 1982. Biol. Rev. 57:29–58; Neill 1948. Herpetologica 4:158; D. Formanowicz, pers. comm.); this is the first record of *E. fasciatus* as a victim. Because hatchling lizards are small, they easily may be trapped in spider webs, which are not only extremely strong and adhesive, but are also placed in locations where lizards are apt to run or fall. Once caught, struggling further entangles the lizard, making escape nearly impossible. In this case, the nearby spider could not have captured the lizard because mature male *Achaeranea* do not construct webs, but it still could have eaten the lizard.

We thank James Wagner for identifying the spider and E. D. Brodie III for his helpful comments.

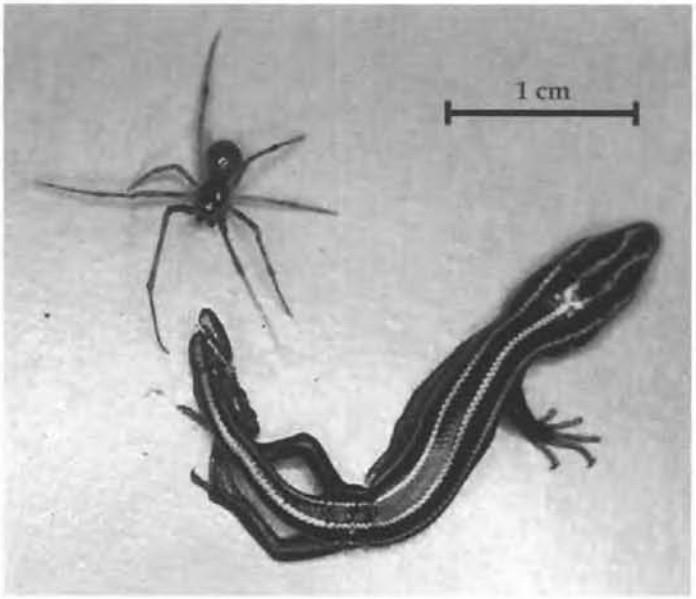

FIG. 1. The entrapped skink and the nearby male spider. The lizard's hind limbs and left forelimb are immobilized, held in place by silk wrapped around its body and tail. The distal portion of the tail is broken off and bound by silk to the rest of the tail.

Submitted by **STEPHANIE M. WELTER**, Center for Ecology, Evolution, and Behavior, University of Kentucky, 101 T. H. Morgan Building, Lexington, Kentucky 40506-0225, USA, and **JOHN E. FAUTH**, Department of Biology, College of Charleston, 66 George Street, Charleston, South Carolina 29424-0001, USA.

PACHYDACTYLUS BIBRONII (Bibron's Gecko). **PREDATION.** Seven left dentaries, seven right dentaries (maximum length 16.04 mm), two left maxillae, four right maxillae (maximum length 13.63 mm), and a single frontal bone (11.01 mm length, 11.14 mm across parietal border) belonging to a minimum of seven large gekkonid lizards were recovered from disso-

ciated pellets of the Cape eagle owl, *Bubo capensis*. Pellets were collected by W. R. Branch and D. Vlok on 8 April 1994 beneath a roost among large jumbled granite boulders at the base of the Ploegberg, Richtersveld National Park, Northern Cape Province, South Africa. Patterns of skin coosification on the frontal and on the prefrontal process of the maxillae allowed determination of at least these elements to species. Some dentaries, however, could also belong to the very similar species *Pachydactylus laevigatus*, which occurs in sympatry with *P. bibronii* throughout large portions of the Northern Cape and western Namibia. All of the elements measured appear to be from adult geckos, and the largest bones are comparable with those of animals >100 mm SVL. Twelve fragmented small mammal skulls were also recovered from the pellets. This species of owl is typically a hunter of mammals (Maclean 1985. Robert's Birds of Southern Africa, 5th ed. John Voelcker Bird Book Fund, Cape Town. 848 pp.), and lizards have rarely been recorded from its diet (Gargett and Grobler 1976. Arnoldia (Rhodesia) 8(7):1-7). This appears to be the first confirmed record of *P. bibronii* in the diet of a South African owl.

Submitted by **AARON M. BAUER,** Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085-1699, USA, and **WILLIAM R. BRANCH**, Department of Herpetology, Port Elizabeth Museum, P.O. Box 13147, Humewood 6013, South Africa.

PHRYNOSOMA CORONATUM BLAINVILLII (San Diego Horned Lizard). **GROWTH**. *Phrynosoma coronatum blainvillii* were marked and released from April 1990 to October 1991 on two 1 ha study sites in southern California, USA. The first study site was located at TlS R3W S10 SW1/4 in Redlands, San Bernardino Co., and the second at T4S R4W S24 SW1/4 on the University of California's Motte Rimrock Reserve, Perris, Riverside Co. Recaptures of eight individuals (four adults and four hatchlings) permitted calculation of growth rates. Daily growth [reported in mm snout-vent length (SVL)/day] between recaptures was calculated for each individual then averaged for hatchlings and adults, separately. Individuals >75 mm SVL were considered adults, those between 75 mm and 50 mm SVL were considered juveniles, and <50 mm SVL were considered hatchlings.

Phrynosoma c. blainvillii hatched during a short period from late July to early August, and ranged from 27–31 mm SVL when first captured. One male hatchling was recaptured twice with an increase of 0.345 and 0.200 mm/day at 13 and 15 days between measurements, respectively. Another male hatchling was recaptured once (16 days between measurements) and grew 0.375 mm/day. Two female hatchlings were recaptured once, each with 13 days between measurements; one grew 0.0769 mm/day and the other 0.154 mm/day. Overall mean growth of hatchlings was 0.230 mm/day (SD = 0.133; N = 4). One hatchling measured 47 mm SVL on 1 October 1990 before its first winter.

Juvenile growth was not calculated because no individuals were recaptured. Two juveniles, however, were captured following what was thought to be their first winter: a male measuring 50 mm SVL was captured in February 1991 and a female measured 66 mm SVL in May 1990.

Mean growth for adult horned lizards was 0.105 mm/day (SD = 0.169; N = 4). One male was recaptured once 32 days after initial capture and grew 0.125 mm/day. Two other males were recaptured twice; one of these grew 0.493 and 0.0541 mm/day at 345 and 74 days between measurements, respectively, and the other was recaptured at 230 and 55 days between measurements with no measurable growth and growth of 0.127 mm/day, respectively. One female was recaptured three times during the study at 68, 324, and 49 days between measurements with growth of 0.0400 mm/day detected only during the first interval.

I thank B. H. Brattstrom for his many helpful discussions of the natural history of the San Diego homed lizard as well as his review of this manuscript. The California Department of Fish and Game kindly provided a Memorandum of Understanding (issued to BHB) to legally conduct research on *P. c. blainvillii.*

PHRYNOSOMA CORONATUM BLAINVILLII (San Diego Horned Lizard). **CONSERVATION**. On 8 August 1994, while conducting surveys on Marine Corps Air Station (MCAS) El Toro, Orange Co., California, USA, I found a dead *Phrynosoma coronatum blainvillii* that apparently died of exposure or dehydration after the horns on its head became entangled in an erosion control blanket. The lizard pushed its head through the mesh of the blanket, but was unable to extricate itself or to continue through the mesh. The blanket was installed along the Foothill Transportation Corridor adjacent to the northeast border of MCAS El Toro. The installation of erosion control blankets is often required on slopes during and after construction projects. *Phrynosoma c. blainvillii* is a federal Category 2 species (being considered for listing as threatened or endangered under the Federal Endangered Species Act of 1973, as amended) and a California Species of Special Concern (California Department of Fish and Game designation) primarily due to loss of habitat throughout its historic range and planned development. The construction of linear transportation corridors through miles of horned lizard habitat may have a substantial impact on the populations of horned lizards in the vicinity. The placement of erosion control blankets along each side of these transportation corridors may act as an additional (if not more formidable) barrier to horned lizard movements. Considering the potential impact the use of erosion control blankets may have on *P. c. blainvillii,* it is recommended that alternative erosion control measures be assessed for feasibility along transportation corridors throughout the species' range.

I thank Barbara Wilson from MCAS El Toro for permitting me to disseminate this information and Thomas E. Olson for reviewing a draft of the manuscript.

TROPIDURUS TORQUATUS (NCN). **HOME RANGE**. The home range of an individual is the area where it normally lives, excluding migrations, emigrations, or unusual erratic wanderings (Brown and Orians 1970. Ann. Rev. Ecol. Syst. 1:183–199). *Tropidurus torquatus* is a terrestrial, heliophilous lizard, abundant in "Restinga" environments in southeastern Brazil. Here, I present home range data for this species. I conducted this study in July 1993 at the Reserva Florestal da Companhia Vale do Rio Doce (19°10'S; 40°00'W, 50 m elev., 1500 mm annual rainfall),

Linhares municipality, Espirito Santo State, Brazil. *Tropidurus torquatus* was studied in a habitat locally called "Nativo," characterized by white sandy soil, low sparse shrubs, and patches of bromeliads and grasses. Inside a 50 x 100 m study plot, the lizards were captured (pitfalls with drift fences and noosing), measured, sexed, marked with paint, and released at their original positions. Individual lizards were precisely located on the plot according to a system of X,Y coordinates. To locate marked individuals I slowly walked inside the plot searching for them with binoculars. The positions of known lizards were marked with flags. To estimate home range I used the convex polygon method. I considered for analysis only those individuals with three or more positions.

Tropidurus torquatus showed sexual size dimorphism, with males being larger (mean = 71.6 ± 3.7 (SD) mm; N = 6) than females (mean = 58.2 ± 2.6 mm; N = 17) (t-test, t = 9.66; $p < 0.001$); similarly, males (mean = 15.0 ± 1.7 g; N = 6) were heavier than females (mean = 7.6 ± 1.3 g; N = 18) (t = 11.38; $p < 0.001$). Juveniles ranged in size from 30.7 to 62.1 mm (N = 39). The size of the home range of males was different from that of females and juveniles (ANOVA $F_{2,13} = 12.56$; $p = 0.001$). Males occupied larger areas (mean = 57.9 ± 18.0 m^2; N = 4) than females (mean = 11.8 ± 11.4 m^2; N = 6) (Tukey 46.07; $p = 0.001$) and juveniles (mean = 17.5 ± 16.3 m^2; N = 6) (Tukey 40.35; $p = 0.003$). Juveniles' home ranges were not significantly greater than those of females (Tukey 5.72; $p = 0.79$). The home range ratio (male/female) was 4.8.

Individuals of *T. torquatus* occupied fixed areas. The mean home range size of both sexes at this site was smaller than that known for other *Tropidurus* species (Stamps 1983. *In* R. B. Huey et al., eds., Lizard Ecology, pp. 169–204. Harvard Univ. Press, Cambridge, Massachusetts), but follows the pattern of males using larger areas than females. A voucher specimen from the population is housed at the Museu de História Natural da UNICAMP (ZUEC 1774).

I thank the Companhia Vale do Rio Doce and Fundação MB for logistic support, C. F. Rocha for suggestions on field methods and this note, and A. Teixeira for helping with data analysis. L. A. Fitzgerald and anonymous reviewers improved an earlier draft. CNPq provided financial support (Process -132314/92-4).

SERPENTES

CHIONACTIS OCCIPITALIS ANNULATA (Colorado Desert Shovelnose Snake). **PREDATION** and **DIURNAL ACTIVITY.** On 22 July 1984, 16.7 km east of the junction of Interstate 8 and Highway 98 and 0.3 km south of Highway 98, Imperial Co., California, USA in the Yuha Basin (NE 1/4 SEC 19, T17S, RIIE; 110 m elev.), Bruce Barry discovered two adult *Chionactis occipitalis* impaled on an ocotillo, the apparent prey of a loggerhead shrike (*Lanius ludovicianus*). The habitat at the site is characterized as creosote bush scrub. At the time of the observation (1048 h; air temperature 32°C) one snake appeared to have been recently killed and measured 39.4 cm total length and was impaled 3.5 cm behind the snout. The second individual was desiccated. Both snakes were impaled about two meters above the ground and found intact with no evidence of mutilation. The site was visited for nearly 1.5 h and shrikes were not seen in the vicinity at this time.

This record represents the first record of a passerine bird preying upon *C. occipitalis* and apparent mid-summer diurnal activity of *C. occipitalis*, or perhaps seasonal crepuscular hunting of the loggerhead shrike. Impaled nocturnal prey (scorpions and solpugids) have been observed in the desert of Baja California (Clark and Frohlich 1982. Pan-Pacific Ent. 58:164).

We thank Kent R. Beaman and Michael A. Patten for their helpful comments on the manuscript.

Submitted by **CLARK R. MAHRDT** and **BENJAMIN H. BANTA**, Southwest Biological Associates, 9847 Willow Lane, Escondido, California 92029, USA.

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake). **FORAGING.** An observation of predation by a radio-tagged *E. o. obsoleta* on brown-headed nuthatch (*Sitta pusilla*) nestlings may help explain patterns of avian nest predation by semi-arboreal snakes and adaptive responses of breeding birds. On 29 May 1993 at 1500 h a female *E. o. obsoleta* (97 cm SVL) implanted with a motion-sensitive radio transmitter was located in a clearcut in the Ouachita National Forest, Arkansas, USA. The snake was beneath a log 1.5 m from a post oak (*Quercus stellata*) snag containing a cavity nest of *S. pusilla* 1.7 m above ground. The nest contained at least three nestlings nearly ready to fledge.

Adult nuthatches were making frequent feeding visits to the nest, when at 1603 h rain began, temperature fell 10°C, and the birds ceased their visits. At 1619 h the snake emerged and attempted to climb the snag, which was devoid of bark at its base and smooth to the touch. It abandoned the attempt after 30–45 s and retreated to the log.

At 2024 h (1 min past sunset) the snake attempted to climb the barkless portion of the snag, but descended after 7 min. It began another climb at 2034 h, struggling 3 min on the smooth surface and extending only 85 cm. At last it secured a grip on a slab of bark and moved upward. Upon reaching the cavity the snake ingested the nestlings, the posterior half of its body hanging outside the cavity. At 2131 h it emerged, climbed up 1.5 m, then descended to the ground. At 2234 h the snake was still moving. The next day at dawn the snake was located in grass 4.1 m from the snag. At 0940 h it began a move of 70 m, then entered a cavity 3 m high in a snag and remained there at least 27 h.

Our observation was typical in that most accounts of avian nest predation by *E. obsoleta* report predation on cavity-nesting species rather than open-nesters (Withgott 1994. M.S. thesis, Univ. Arkansas, Fayetteville. 147 pp.). In addition, *E. obsoleta* often attack nests in the latter part of the nestling stage (Neal et al. 1993. Wildl. Soc. Bull. 21:160–165; Withgott, *op. cit.*), a pattern also noted for *Pituophis melanoleucus* (Eichholz and Koenig 1992. Southwest. Nat. 37:293–298).

By climbing the nest snag at dusk, the snake we observed was able to avoid harassment by nuthatches defending the nest and was able to lessen its vulnerability to diurnal predators such as hawks.

The snake's difficulty gripping the snag's smooth, barkless surface is of interest. Had the entire trunk lacked bark, it seems likely the snake could not have reached the nest. Birds nesting in such smooth-surfaced snags may possess some degree of protection from predation by climbing snakes. Withgott (*op. cit.*) found in experiments with *E. o. obsoleta* that climbing ability decreased sharply with increasing trunk smoothness. Several woodpecker species at our study site preferred barkless snags as nest sites (Withgott, *op. cit.*). Such nest-site selection may be an adaptive response to the threat of nest predation by semi-arboreal snakes.

We thank R. Kannan, S. Lima, and P. Rodewald for comments on the manuscript. Funding was provided by Ouachita National Forest, Southern Forest Experiment Station, and Arkansas Audubon Society Trust.

FARANCIA ABACURA (Mud Snake). **DEATH FEIGNING.** Incidents of death feigning have been reported for a number of snake species, including xenodontine colubrids (Carpenter and Ferguson 1977. *In* C. Gans and D. W. Tinkle (eds.), Biology of the Reptilia, Vol. 7. pp 335–554. Academic Press, New York; Gehlbach 1970. Herpetologica 26:24–34). Since those reviews, additional species have been reported to letisimulate (e.g., Tryon and Guese 1984. Herpetol. Rev. 15:108). Davis (1948. Copeia 1948:208–211) observed a juvenile *Farancia abacura* feign death in captivity and included the following description: "The specimen...when annoyed by poking or patting with the hand, persistently thrust its head under the coils of the body and elevated the tail...with the conspicuously colored underside uppermost. Additional molesting caused the snake to turn over on its back, thus exhibiting the entire brilliantly colored underside. The animal would lie quietly in this position...." Davis (*op. cit.*) noted that it was remarkable that death feigning had not been reported previously for *F. abacura*, especially by Meade (1946. Sci. Mon. 63:21–29), who apparently handled over one hundred individuals. Here we report observations of death feigning in *F. abacura* in captivity, and attempt to reveal why the behavior has not been observed in adults.

On 3 August 1994 a gravid female (SVL = 110.5 cm , mass = 611.2 g) *F. abacura* was captured (by RAF) following a heavy rain along the Pascagoula River near Vancleave, Mississippi, USA. We housed this snake until she deposited 24 eggs, 14 of which hatched in the laboratory 11–16 September. The eggs were placed in moist vermiculite and incubated at a constant temperature (30°C). On day 42 of incubation the snakes began to hatch, with the last snake hatching on day 47.

Shortly after emergence, gentle handling would cause the snakes to roll up their tails, as reported by Davis (*op. cit.*). If further provoked (e.g., when picked up, or when lightly tapped on the dorsum) the snakes would thrash once or twice, empty their cloacal contents, and turn over, remaining motionless (Fig. 2). If harassed while in this position, the snakes would often crawl away on their dorsum, keeping the brightly colored ventrum visible at all times. The snakes (mean = 17.54 ± 1.087 cm SVL, mean = 4.40 ± 0.841 g, N = 14) feigned death in a variety of positions, from curled up to relatively straight, and righted themselves within four minutes, if left alone. All 14 snakes were harassed at least once, and all feigned death.

Apparently, death feigning has not been observed in adult *F. abacura* (the individual Davis observed was 29.8 cm (TL). One of us (JSD) has captured and handled several adult *F. abacura* without inducing the behavior. We thus conclude that either (1) there is an ontogenetic loss in the behavior, or (2) the behavior is difficult to induce in adults. We tested these ideas in an attempt to explain the apparent absence of the behavior in adults.

The timely arrival of a road killed barred owl (*Strix varia*) prompted us to perform a mock predation event. Owls and hawks are ophiophagus (Earhart and Johnson 1970. Condor 72:251–264), and probably represent a significant threat to adult mud snakes.

The same adult female mud snake was placed on the floor of the laboratory. One of us held the owl over the snake, brushing the talons and feathers against the snake's dorsum. The action of the owl's talons were simulated by grabbing the snake repeatedly at mid-body and near the head. After approximately one minute of harassment, the snake everted its cloaca, discharging its contents on and around itself (Fig. 2). It then thrashed its tail, and began turning it over. Finally it made a tight coil with its head hidden, and twisted over on its back, exposing its entire ventral surface (Fig. 2). The snake remained motionless for several minutes. It may be worth noting that the juvenile snakes did not hide their heads, as did the adult.

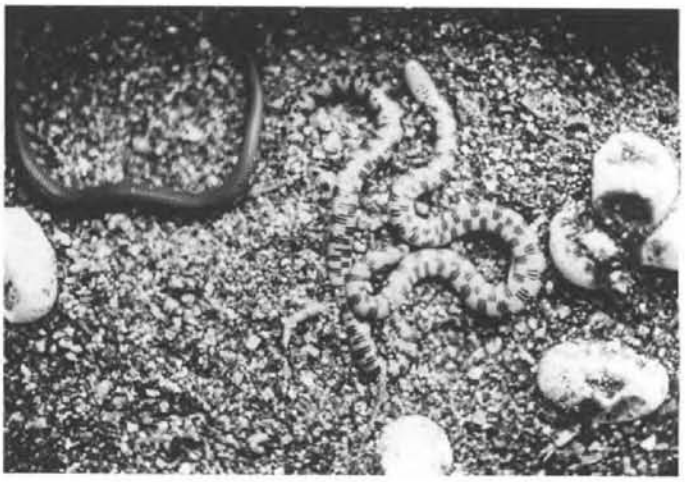

FIG. 1. Neonate *Farancia abacura* feigning death.

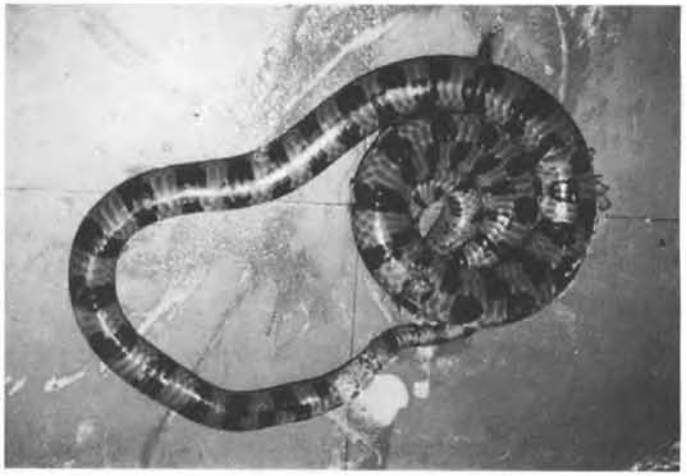

FIG. 2. Adult female *Farancia abacura* feigning death. Note the cloacal discharge.

Tryon and Guese (*op. cit.*) considered the failure of hatchling *Lampropeltis alterna* to death feign to be the result of an absence of odors or other natural stimuli from natural (versus unnatural) predators. To test whether or not the snake recognized the owl as a predator (i.e., by olfaction) or simply responded to increased molestation, the snake was harassed 3 days later by hand. Within one minute similar death feigning behavior resulted. Thus, we were able to confirm that death feigning can be induced in adult *F. abacura* without any specific olfactory cues. It appears that adult *F. abacura* require a greater degree of "molesting" than juvenile snakes based on this report, hence the lack of documented

death feignings induced by capturing and handling. It is possible that *F. abacura* does not perceive enough threat while enduring capture and passive handling to elicit the death feigning response.

Apparently, in several species of snakes known to feign death, only some individuals exhibit the behavior (Gelbach, *op. cit.*; Tryon and Guese, *op. cit.*), indicating the possibility that death feigning is a polymorphic trait. It should be noted that while all 14 provoked snakes in this study feigned death, they were full siblings, and thus represent a limited sample size. Additionally, death feigning in the adult female might be expected since her progeny possessed the behavior. The possibility remains that it is merely difficult to induce death feigning due to the lack of sufficient stress (e.g., as produced in attempted predation encounters) necessary to induce the behavior. Further manipulations involving more individuals under more natural conditions might help clarify whether this behavior is ubiquitous within the species.

LAMPROPELTIS TRIANGULUM NELSONI (Milk Snake). **PREDATION.** The majority of hawks feed mainly on birds, rodents, batrachians, reptiles, and insects (Bent 1961. Life History of North American Birds of Prey. Dove Publ., pp. 147–292). Records of predation by raptors on *Lampropeltis triangulum* are scarce (Williams 1988. Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. Milwaukee Publ. Mus., 176 pp.).

On 2 February 1992 we observed a gray hawk (*Buteo nitidus*) on the banks of the Huaynamota River near Sabinos Ranch, 21°40'N, 104°33'W, 70 km N of the city of Tepic, Nayarit, México. The area is located in the foothills of the Sierra Madre Occidental, with a tropical deciduous forest and a hot dry climate. We observed the gray hawk with binoculars as it attempted to pick something up between two big rocks. Within two minutes it caught a small serpent and carried it to an 8 m tall tree, where it began to eat it. The gray hawk was shot by a local "huichol." We had the opportunity to dissect it, and found it had eaten a young *L. t. nelsoni*, 18 cm total length. The bird, a young male, was deposited in the Bird Collection (#18124) and the snake in the Herpetological Collection (#8140), both of the Instituto de Biología, UNAM, in México City.

We thank Gustavo Casas for the identification of the snake and comments on the manuscript, William López-Forment for revision of the manuscript in English, Alejandro Landín for his assistance in the field, and the helicopter service of the Comisión Federal de Electricidad (CEF) for transportation to the Huaynamota River.

NERODIA ERYTHROGASTER TRANSVERSA (Blotched Water Snake). **REPRODUCTION.** On 25 August 1994, Colorado River Municipal Water District (CRMWD) personnel set minnow traps along the shoreline adjacent to the emergency spillway at Ballinger Municipal Lake (BML), formerly Lake Moonen, Runnels Co., Texas, USA. On 26 August, between 0900 and 0930 h, three *Nerodia erythrogaster* were captured [2 adults (male and female), 1 juvenile]. The adult female was gravid and estimated by palpation to contain 15 embryos. We retained the snake for observation.

Between 0845 and 0930 h on 17 September 1994, the female (SVL 866 mm, tail 170+ mm, mass 350 9) gave birth to 14 neonates and four infertile masses. Litter sizes are 5–25 for this species (Barton 1948. Herpetologica 4:198; Conant 1949. Copeia 1949:1–15; Diener 1957. Herpetologica 13:202–211; Wright and Wright 1957. Handbook of Snakes of the United States and Canada. Comstock Publ. Assoc., Ithaca, New York). Diener (*op. cit.*) suggested a mean litter size of 12 (range 5–21 ova) for a sample of five individuals.

Of the 14 neonates born in our lab, 8 were males and 6 were females. Measurements of the 8 neonate males were: TL range = 247–276 mm, mean = 260.9 mm, SD = 9.1; mass range = 5.0–6.2 g, mean = 5.4 9, SD = 0.4; neonate females: TL range = 244–277 mm, mean = 258.8 mm, SD = 10.2; mass range = 4.7–6.0 g, mean = 5.3 g, SD = 0.4; overall litter measurements were: SVL range = 185–214 mm, mean = 197.8 mm, SD = 7.8; tail length range = 56–69 mm, mean = 62.4 mm, SD = 4.3; mass range = 4.7–6.2 g, mean = 5.0 g, SD = 0.4. After parturition the adult female weighed 248 g. The total litter mass (excluding the infertile masses) was 75.5 g and the relative clutch mass (RCM = ratio of total litter mass to postpartum female mass + total litter mass) was 0.233. This compares to a RCM of 0.300 for *Nerodia rhombifer* (Plummer 1992. Copeia 1992:1096–1098), 0.259 for *Regina grahami* (Thornton and Smith 1995. Herpetol. Rev. 26:102–103), and 0.295 for 22 species of viviparous colubrids (Seigel and Fitch 1984. Oecologia (Berl.) 61:293–301). All the neonates sloughed immediately after birth. Diener (*op. cit.*) reported that in the southern part of the range of *N. erythrogaster*, mating occurs from early April through May. Assuming a three-month period of gestation (Betz 1963. Copeia 1963:692–697), ovulation of this *N. erythrogaster* probably occurred in late June. The adult female and all viable young were released at the capture site.

We thank the Colorado River Municipal Water District for funding and facilities. Collections were made under the authority of the Texas Parks & Wildlife Department Scientific Permit No. SPR-790-208 to CRMWD. James R. Dixon reviewed an earlier version of this manuscript.

NERODIA VALIDA (Pacific Water Snake). **PREY**. *Nerodia valida* is a scarcely known snake of the west coast of mainland México and the Cape Region of Baja California Sur. Only general data on its diet have been reported (Stebbins. 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.). Our observations were made on 14 August 1994, along Arroyo Boca de la Sierra in the Sierra de la Laguna, Baja California Sur, México (23°24'N, 109°49'W; 300 m elev.). It was the first sunny day after some rain, so the arroyo carried water and the first ponds of the year were formed. We walked 3 km along the arroyo at 1200–1400 h and 1500–1600 h.

We observed in the water and on sandy banks >500 adult *Bufo punctatus*, 80% of which were in amplexus. We also observed 27 individuals of *Nerodia valida*. Nineteen were juveniles <20 cm TL and 8 were adults. Two were swallowing a pair of toads in amplexus, and another was engorged and appeared to have eaten

other pair of toads. A fourth adult *N. valida* was pursuing another pair of toads.

It is remarkable that the male toads did not release their embrace despite the immediate risk of being eaten. Large breeding aggregations are characteristic of anurans living in subtropical desert areas (Wells. 1977. Anim. Behav. 25:666–693) and, apparently in these cases the toads were compromised between the opportunity to breed when conditions were favorable, and avoiding predation.

SEMINATRIX PYGAEA PYGAEA (Black Swamp Snake). **PREDATION.** On 31 January 1995 at Lake Woodruff National Wildlife Refuge in central Florida, USA, a nine-banded armadillo (*Dasypus novemcinctus*) was observed preying on a black swamp snake. The time was late afternoon (ca. 1630 h) and the surface temperature was ca. 15°C. The snake was 18.5 g in mass, 26.5 cm SVL and, though still alive when captured, was mutilated from midbody to tail due to the armadillo's mastication. The event took place in a mesic-hydric semi-deciduous (hammock) forest in an area of saturated, mucky soil.

Armadillos feed mainly on insects but also consume some reptiles. Breece and Duci (1985. *In* G. G. Montgomery (ed.), The Evolution and Ecology of Armadillos, Sloths, and Vermilinguas: Symposium on the Evolution and Ecology of Xenarthra, pp. 419–427. Smithsonian Inst. Press, Washington, D.C.) reported that small reptiles and amphibians were the only vertebrates found in stomach contents of 50 adult armadillos from Alabama.

In the southeastern U.S., armadillos (*D. novemcinctus*) may ingest more reptiles during winter than other seasons (Fitch et al. 1952. J. Mammal. 33:21–27). For example, Breece and Duci (*op. cit.*) found that in the winter season *Anolis carolinensis* constituted 24% by volume of ingested matter while the yearly average was only 3%. One hypothesis for this discrepancy between winter and overall feeding is that cool weather may make reptiles slower and therefore easier for armadillos to capture. Our observation is consistent with this hypothesis.

SISTRURUS MILIARIUS BARBOURI (Dusky Pigmy Rattlesnake). **MAXIMUM SIZE.** The reported maximum size for this race, the largest of the species, is 80.3 cm (31 1/2 inches) (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

In the spring of 1981, Mitchell Harris collected an adult male *Sistrurus miliarius barbouri* off Rt. 60 at a farm ca. 30 mi west of Vero Beach in Osceola Co., Florida, USA. The specimen was given to the senior author, who maintained it in captivity from March 1981 until April 1993 (13 years, one month), when it died. We estimate the age of this snake to be ca. 20 years, because it was ca. 63.5 cm (25 in.) in length when caught in the wild. Its weight (on 23 July 1988) was 23.2 ounces (658 g). At its death, the specimen measured 73.8 cm (29 in.) SVL and 9.4 cm (3.7 in.) tail length, for a total length of 83.2 cm (32.8 in.), a new maximum size for this race and the species. During the early part of its captivity, this specimen maintained only 2–3 rattle segments. However, despite repeated sheddings during the remainder of its life, these original segments wore down and the snake ceased adding any rattle segments. The specimen was preserved and deposited in the Florida State Museum of Natural History, Gainesville (UF-FSM 87590); color slides were deposited earlier (1987) at the Natural History Museum, The University of Kansas, Lawrence (KU Color Slides 7614-7615).

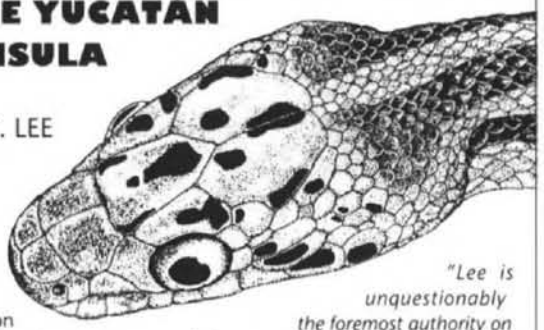
THAMNOPHIS SIRTALIS PICKERINGII (Puget Sound Garter Snake). **FORAGING** and **ARBOREALITY**. On 16 July 1995, between 1300 and 1500 h, we observed three individuals of *Thamnophis sirtalis pickeringii* actively climbing in willow (*Salix* sp.) branches between 0.5 and 2.0 m above the surface of a shallow lake in Dupont, Pierce Co., Washington, USA (NW1/4 S36, T19N, R1E). We watched one individual for 1.5 h and observed it hunting and feeding upon newly metamorphosed Pacific tree frogs (*Pseudacris regilla*) that were clinging to leaves and branches. We saw it take at least three small *P. regilla* as it moved rapidly through the branches. The *Thamnophis* appeared to take the small frogs on the fly as they attempted to leap away. Periods of active hunting lasted 30–60 s, between which, the snake laid motionless in the willows basking, partially concealed by leaves and branches. The individual moved in a horizontal diameter of approximately 1.5 m, and remained between 1.5 and 2.0 m above the water during the 1.5 h of observation.



Submitted by **WILLIAM P. LEONARD**, Washington Natural Heritage Program, P.O. Box 47016, Olympia, Washington 98504-7016, USA, and **NICHOLAS P. LEONARD**, 223 Foote St. NW, Olympia, Washington 98502, USA.

Anolis carolinensis (American Anole). Illustration by Dan C. Holland.

THE AMPHIBIANS AND REPTILES OF THE YUCATÁN PENINSULA

JULIAN C. LEE

Deforestation now threatens the ecosystem of the Yucatán Peninsula—an area including northern Guatemala, Belize, and southeastern Mexico. This splendidly illustrated book by the world's leading authority on Yucatán herpetology documents the natural history of all native and introduced species of reptiles and amphibians. Lee describes some 181 species of frogs, toads, salamanders, snakes, lizards, turtles, and crocodiles.

"Lee is unquestionably the foremost authority on the herpetology of the Yucatán. The section on ethno-herpetology will be of interest to nonspecialists and herpetologists alike."

—Jonathan A. Campbell, coauthor of *The Venomous Reptiles of Latin America*

NEW- REPTILE BOOKS FROM RALPH CURTIS

DANGEROUS SNAKES OF AFRICA- Natural History; Species Directory; Venoms and Snakebite By Stephen Spawls and Bill Branch (1995) Fully illustrated guide to more than 90 species. Latest identification and distribution data. Snakebite and first aid treatment. Color photos of almost all the species covered. *192pp., 120 Color photos. 93 maps. Hardcover* **$ 39.95** ***(Publication date - Due August 1995)***

A Photographic Guide To The SNAKES And Other REPTILES OF AUSTRALIA By Gerry Swan (1995) This guide covers 231 species of the most commonly seen reptiles. *144pp., 173 Color Photos. 231 maps.* **$ 15.95** ***(Publication date - Due August 1995)***

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19:1–41; for México as it appears in Liner, 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*. Herp. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985(3):802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: Joseph T. Collins (USA & Canadian records only), Museum of Natural History—Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA; Jerry D. Johnson (México and Central America, including the Caribbean islands), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA; Hidetoshi Ota (all Old World records), Tropical Biosphere Research Center, University of the Ryukyus, 1 Senbaru, Nishihara-cho, Okinawa 903-01, Japan; or Gustavo J. Scrocchi (South American records), Instituto de Herpetologia, Fundacion Miguel Lillo, Miguel Lillo 251, 4000 Tucuman, Argentina. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Submissions by e-mail are encouraged where possible**. Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Painter, C. W., and C. M. Milensky. 1993. Geographic Distribution. *Crotalus tigris*. Herpetol. Rev. 24:155–156.

CAUDATA

DESMOGNATHUS AENEUS (Seepage Salamander). USA: GEORGIA: Stephens Co: Panther Creek at Panther Creek Road, Chattahoochee National Forest, 8.8 km NNW of Toccoa. 5 May 1994. Carlos D. Camp and R. Dale Payne. Verified by Joshua Laerm. University of Georgia Museum of Natural History (UGAMNH 24874). Small creek in deciduous cove forest at ca. 270 m elev. New county record; range extension of ca. 15 km (Harrison 1992, Cat. Amer. Amph. Rept. 534:1–4).

Submitted by **CARLOS D. CAMP** and **R. DALE PAYNE**, Department of Biology, Piedmont College, Demorest, Georgia 30535, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ILLINOIS: Kane Co: SE 1/4 Sec. 24 T41N, R8E, marsh along Elgin Road, Elgin. April 1985. Peter L. Meserve. Verified by Thomas Near. HDW-NIU 1609. Documents county record of Garman (1892, Illinois Lab. Nat. Hist. Bull. 3(13):356) for which no vouchers exist, and fills gap between DeKalb and Cook County records (Smith 1961, Bull. Illinois Nat. Hist. Serv. 28:1–298).

HARLAN D. WALLEY, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA.

PLETHODON SERRATUS (Southern Redback Salamander). USA: GEORGIA: Jasper Co: Ocmulgee River at Ga. Rt. 16, Oconee National Forest, 16.5 km W of Monticello. 5 March 1994. Carlos D. Camp, R. Dale Payne, and Jeremy L. Marshall. Verified by Joshua Laerm. University of Georgia Museum of Natural History (UGAMNH 24872–873). Deciduous hillside at ca. 200 m elev. New county record; eastward range extension of ca. 30 km (Camp 1986, Georgia Jour. Sci. 44:136–146).

Submitted by **CARLOS D. CAMP**, **R. DALE PAYNE**, Department of Biology Piedmont College, Demorest, Georgia 30535, USA, and **JEREMY L. MARSHALL**, Department of Biology, University of Mississippi, University, Mississippi 38677, USA.

ANURA

PHRYNOHYAS MESOPHAEA (NCN): BRASIL: BAHIA: Município de Lauro de Freitas: Jardim Aeroporto (12°55'S, 39°15W). 5 October 1994. M. A. de Freitas. Verified by J. P. Pombal Jr. Museu Nacional (MNRJ 17442). First record for northern part of state of Bahia; extends previous geographic distribution to the north (Duellman 1971, Univ. Kansas Nat. Hist. Mus. Occ. Pap. 4–21) mentions *Phrynohyas mesophaea* from the state of Bahia at Santa Cruz. This reference is unclear, because it could be Santa Cruz da Vitoria or Santa Cruz Cabrália. Both sites are relatively close to each other, but 500 km S of this new record. According to Frost (1995, Amphibian Species of the World. Version 2/95. Electronic manuscript maintained under the auspices of the Herpetologists' League), this species is restricted to the Atlantic Forest of southeastern Brasil. However, the holotype is from the state of Rio Grande do Sul in southern Brasil (Frost, *op cit.*). To our knowledge, *Phrynohyas mesophaea* occurs along the Atlantic Forest from Rio Grande do Sul to Reconcavo Baiano in the state of Bahia.

Submitted by **REUBER A. BRANDÃO**, **MARCO ANTÔNIO DE FREITAS**, and **ANTÔNIO SEBBEN**, Laboratório de Fisiologia Animal-CFS/IB, Universidade de Brasília, 70 910-900, Brasília/DF-Brasil.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: MINNESOTA: Dodge Co: wet cow pasture S of Zumbro River, NE 1/4 Sec. 14, T105N, R16W. 30 May 1995. Terry VanDeWalle. Verified by James L. Christiansen. Bell Museum of Natural History (MMNH 13493). New county record (Oldfield and Moriarty 1994, Amphibians and reptiles native to Minnesota. Univ. Minnesota Press, Minneapolis. 237 pp.). Specimen was collected during a search for *Acris crepitans* in southeastern Minnesota conducted for the Minnesota County Biological Survey; no *A. crepitans* were found.

Submitted by **TERRY J. VANDEWALLE**, Biology Department, Des Moines Area Community College, Ankeny, Iowa 50021, USA, and **CHRISTOPHER D. VAN GORP**, Department of Biology, Drake University, Des Moines, Iowa 50311, USA.

RANA CAPITO (Gopher Frog). USA: TENNESSEE: Coffee Co: Hill Chapel Road, NE section of Arnold Engineering and Devel-

opment Center (AEDC), (35°24'15"N 86°3'40"). 12 July 1993. B. T. Miller and T. Casey. Verified by A.F. Scott. Middle Tennessee State University (MTSU 72A). Juvenile specimen (36 mm SVL) captured while road-cruising during a rainstorm. NE section of AEDC is characterized by low relief with many temporary and variably-sized bodies of water, including hardwood swamps (e.g., Sinking Pond, Westall Swamp). Specimen represents the first record for state and most inland record for the species (Redmond 1985, A Biogeographic Study of Amphibians in Tennessee. Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.; Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). A disjunct population of *Rana capito* has been reported in Shelby County, Alabama (Mount 1975, The Reptiles and Amphibians of Alabama. Publ. Auburn University, Alabama. 347 pp.; Guthrie 1985, Herpetol. Rev. 16:31.), ca. 225 km southwest of AEDC, and the closely related *Rana areolata* occurs within the coastal plain of western Tennessee (Redmond 1985, *op. cit.*) less than 200 km west of AEDC.

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA, and **DAVID L. CAMPBELL**, The Nature Conservancy, 50 Vantage Way, Suite 250, Nashville, Tennessee 37228, USA.

RANA CLAMITANS MELANOTA (Green Frog). USA: MISSOURI: Macon Co: South 61 Training Area, Missouri National Guard Macon Area Training Site, W of study plot 18, ca. 4 km NW Excello, 39°39'28"N, 92°30'53"W. 26 June 1994. Angelo P. Bufalino. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 5428). Specimen caught by hand in cattail-filled pond. New county record (Powell, Johnson, and Parmerlee 1993, Missouri Herpetol. Assoc. Newsl. (6):7–26).

Submitted by **ANGELO P. BUFALINO,** The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee, 37044, USA.

TESTUDINES

APALONE FEROX (Florida Softshell). USA: ALABAMA: Mobile Co: Adjacent to lake on Viaduct Street, 0.12 km E U.S. Rt. 43 and 1.36 km S jct. U.S. Rt. 43/State Rt. 158, T3S, R1W. 1989. S. McGee. AUMP 3580 (adult male). Viaduct Street (DOR). August 1993. J. L. Dobie, C. J. Leary, and J. Golden. AUMP 1808–09 (juveniles). All verified by Robert H. Mount. First county record (Mount 1975, The Reptiles and Amphibians of Alabama. Publ. Agric. Exp. Sta. Auburn Univ. vii + 347 pp.; Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Edition. Houghton Mifflin, Boston. xviii + 450 pp.).

Submitted by **JAMES L. DOBIE** and **CHRISTOPHER J. LEARY**, Department of Zoology and Wildlife Science, Auburn University, Alabama 36849-5414, USA, and **JEFFREY GOLDEN**, 201 4th Street North, Pell City, Alabama 35125, USA.

GRAPTEMYS OUACHITENSIS OUACHITENSIS (Ouachita Map Turtle). USA: ALABAMA: Mobile Co: east side Grand Bay, NW of confluence with Raft River, SW 1/4 Sec. 3, T3S, R1E. 18 June 1992. J. L. Dobie, C. J. Leary, and A. E. Davis. AUM 33782. Adult female. Verified by Robert H. Mount. Only specimen known from the Mobile Bay drainage (Mount 1975, The Reptiles and Amphibians of Alabama. Publ. Agric. Exp. Sta. Auburn Univ. vii + 347 pp.). The animal may have been released or moved down the Tennessee-Tombigbee Waterway subsequent to its completion in 1985.

Submitted by **JAMES L. DOBIE** and **CHRISTOPHER J. LEARY**, Department of Zoology and Wildlife Science, Auburn University, Alabama 36849-5414, USA, and **AUBREY E. DAVIS**, The Nature Conservancy of Georgia, 600 Dekalb Street, Apartment H-5, Auburn, Alabama 36830, USA.

LACERTILIA

EUMECES LATICEPS (Broadhead Skink). USA: MISSOURI: Macon Co: South 61 Training Area, Missouri National Guard Macon Area Training Site, ca. 100 m S of study plot 22, ca. 2.1 km NW Excello, 39°39'02"N, 92°29'29"W. 10 August 1994. Angelo P. Bufalino. All verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 5431), 12 August 1994 (APSU 5430), 13 August 1994 (APSU 5429). Specimens caught in drift-fence array; new county record (Powell, Johnson, and Parmerlee 1993, Missouri Herpetol. Assoc. Newsl. (6):7–26).

Submitted by **ANGELO P. BUFALINO**, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee, 37044, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Kenedy Co: 26°46'20"W. 29 December 1995. Glenn Proudfoot. Verified by K. Vaughan and deposited at TCWC. New county record (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station. 434 pp.) that fills in a distributional gap in extreme south Texas.

Submitted by **GLENN PROUDFOOT** and **MICHAEL JAMES MCCOID**, Caesar Kleberg Wildlife Research Institute, Campus Box 218, Texas A&M University, Kingsville, Texas 78363, USA.

LIOLAEMUS BIBRONI (NCN). ARGENTINA: SAN JUAN: Department Calingasta: Arroyo de las Cabeceras, Reserva Estratosferica Natural El Leoncito, 2800–3000 m. January 1993. Eduardo Haene-Sofia Heinonen. Verified by Ricardo A. Martori. Herpetological collection of Museo Argentino de Ciencias Naturales "Bernardino Rivadavia." MACN 35389 (adult male). This voucher represents a new province record, confirms presumed distribution in this area and extends known range at least ca. 100 km N from previously cited localities (Cei 1986, Mon IV. Mus. Reg. Sci. Nat. Torino. 527 pp.).

Submitted by **LUCIANO JAVIER AVILA**, CONICET–Departamento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Estado Postal 9, C. P. 5800, Rio Cuarto (Cordoba), Argentina. E-mail: luciano@unrccc.edu.ar.

SCELOPORUS MAGISTER CEPHALOFLAVUS (Orangehead Spiny Lizard). USA: UTAH: Emery Co: E side Utah Rt. 24, W Green River (city), 0.5 mi S jct U.S. Rt. 6. 15–16 June 1969. Harry L. Taylor. UCM 57431–3. Grand Co: E bank of Green River (river), 19 air km (28 river km) S Green River (city) boat ramp. 12 June 1988. Richard L. Holland. UCM 112–3 slide collection (color). Both verified by Lauren Livo. First county record for Grand County (Tanner 1955, Great Basin Nat. 15:32) where the lizards were exceptionally abundant and easily caught by hand (far different from behavior observed elsewhere within the range of the species). First unambiguous record for Emery County; Tanner (*loc. cit.*) cites "Green River" in Emery County but without clarification whether the river or city was intended, leading Stebbins (1985, Peterson Field Guide to Western Reptiles and

Amphibians. Houghton Mifflin Co., Boston. 336 pp.) to ignore the locality and to map the range for the subspecies with a more southerly northern range limit. These two new records extend the range, as depicted by Stebbins, some 100 km northward.

HARRY L. TAYLOR, Department of Biology, Regis University, Denver, Colorado 80221, USA; **RICHARD L. HOLLARD**, 1855 Garland Land, Boulder, Colorado 80304, USA; **ROSANNA L. HUMPHREY** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309–0315, USA.

SERPENTES

BOA CONSTRICTOR CONSTRICTOR (Boa, Tragavenado). VENEZUELA: ESTADOS MERIDA: DISTRITO SUCRE: Alcabala La Victoria (71°35'W, 8°25'N), 51 km SW Merida, road from Merida to Tovar. 4 January 1995. Roberto Casado and Samanta Zoltan. Verified by Enrique La Marca. Coleccion de Anfibios y Reptiles, Instituto de Geografia, Universidad de Loa Andes (ULABG 3933, cranium only). Adult male (everted hemipenis) found DOR, 1800 mm TL; 1 km SW of Estanques (71°31'W, 8°27'N), road from Merida to Tovar. 19 June 1985. Jaime Pefaur. Verified by Jaime Pefaur. Coleccion de Vertebrados, Facultad de Ciencias, Universidad de Los Andes (CVULA IV 3929). First state records and first Venezuelan Andean localities for the species (Lancini and Kornacker 1989, Die schlangen von Venezuela, Ed. Armitano, Caracas: 82–86).

Submitted by **ROBERTO CASADO B.**, Universidad de Los Andes, Facultad de Ciencias, Ecologia Animal, La Hechicera Merida 5251, Apartado Postal 71, Venezuela, and **SAMANTA ZOLTAN**, Residencia La Floresta, Torre D, Apartamento 6–2, Pedregosa Sur, Merida, Estado Merida, Venezuela.

ERIDIPHAS SLEVINI (Baja California Night Snake). MEXICO: BAJA CALIFORNIA SUR: Arroyo Los Burros at jct. with dirt road from La Purisima to San Juanico, 26°9'54", 112°14'51"W. 29 July 1995. Eric Mellink. Verified by Leek Grismer. LACM PC 1322, SLV = 200 mm. Species was known only from the central-eastern and southern parts of the Peninsula of Baja California, associated with the Sierras de la Asamblea, de la Giganta and de la Laguna (Grismer 1994, The Evolutionary and Ecological Biogeography of the Herpetofauna of Baja California and the Sea of Cortes. Doctoral Dissertation. Loma Linda University, Riverside, California. 677 pp.). This is the first record of the species in the western part of the peninsula. Specimen was found in the dry bed of a rocky wash coming down to the west side of the Sierra de la Giganta, over the Magdalena plains. The nearest known locality lies about 65 km to the east (Grismer, *op. cit.*).

Submitted by **ERIC MELLINK**, Centro de Investigación Científica y de Educación Superior de Ensenada, Apartado Postal 2732, Ensenada, Baja California, México.

FICIMIA PUBLIA (Blotched Hooknose Snake). MÉXICO: JALISCO: MUNICIPALITY OF LA HUERTA: Rancho Cuixmala, Carretera Federal 200, 3 km NW of Emiliano Zapata (19°22'44"N, 104°59'09"W). 6 July 1995. Andres Garcia and Marciano Valtierra. Museo de Zoologia, Facultad de Ciencias, Universidad Nacional Autonoma de Mexico (MZFC 7768). Verified by Fernando Mendoza. First record for the state of Jalisco and a range extension northwestward of ca. 612 km (airline) along the Pacific coast from records reported in central Guerrero [Hardy 1975, J. Herpetol. 9:133–168; Hardy 1980, Cat. Amer. Amph. Rept. (254):1–2.].

Submitted by **ANDRES GARCIA** and **MARCIANO VALTIERRA-AZOTLA**, Fundacion Ecologica de Cuixmala, A.C. Avenida Cometa 2910, C. P. 44520, Guadalajara, Jalisco, México.

GRAYIA THOLLONI (Thollon's Water Snake). SENEGAL: CAP-VERT REGION: Sebikotane, 14°45'N, 17°08'W. 1963. R. P. Berhaut. Verified by Ivan Ineich. Museum National d'Histoire Naturelle at Paris (MNHN 1964. 145). Second record for Senegal (Trape and Mane 1995, Herpetol. Rev. 26:156) and third record for West Africa W of Nigeria (Hughes 1983, Bonn. zool. Beitr. 34:311–356; Dunger 1972, Nigerian Field 37(1):21–38). Specimen was previously erroneously determined as *Grayia smithii* on the MNHN register by Villiers who gave "North Nigeria to Lake Tanganyika" as distribution for the species (Villiers 1975, Les Serpents de l'Ouest Africain. Institut Fondamental d'Afrique Noire, Init. Etudes Afr. n°2:1–195, 3rd ed.). This new locality is situated 130 km (airline) NW of the previous northwesternmost known locality.

Submitted by **OLIVER PAUWELS**, Museum National d'Histoire Naturalle, Laboratoire de Zoologie (Reptiles et Amphibiens), 25 rue Cuvier, F–75005 Paris, France, or Koninklijk Museum voor Midden-Africa, Vertebrate Section (Herpetology), Steenweg op Leuven, B–3080 Tervuren, Belgium.

HETERODON PLATIRHINOS (Eastern Hognose Snake). USA: OKLAHOMA: TEXAS CO: near Eva. 15 October 1995. Kirie Willimon. Verified by John E. Simmons. KU Color Slides 11225–227. Second record for county; extends range ca. 30 mi WNW of previous record for county (Webb 1970, Reptiles of Oklahoma. Stovall Mus. Publ. No. 2. xi + 370 pp.). Corroborates old (1927) record from adjacent Morton County, Kansas (Collins and Collins 1991, Reptiles and Amphibians of the Cimarron National Grassland, Morton County, Kansas. Publ. U.S. Forest Serv., Elkhart, Kansas. vii + 60 pp.).

Submitted by **KIRIE WILLIMON**, Cimarron National Grasslands, P. O. Box 300, Elkhart, Kansas 67950, USA, and **JOSEPH T. COLLINS**, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA.

All verified by William Lamar. These records were never previously published and the occurrence of this taxon in northeastern Brazil was questionable without reliable museum vouchers (Campbell and Lamar 1989, The Venomous Reptiles of Latin America. 425 pp.). These specimens reveal a coastal Atlantic distribution for this snake from Rio de Janeiro to Paraíba (with some exceptions owing to the extensive fragmentation of the Atlantic Forest), and west to Piauí (ecotone Cerado-Caatinga).

Submitted by **LUCIANA LYRA CASAIS E SILVA**, Laboratório de Herpetologia, Instituto Butantan, Avenida Vital Brazil 1500, Butantan, 05504-900, São Paulo, São Paulo, Brazil.

SIBON ANNULIFERUS (Western Snail-eating Snake). MÉXICO: JALISCO: MUNICIPALITY OF LA HUERTA: Reserva de la Biosfera Chamela-Cuixmala, Carretera Federal 200, 4 km NW of Emiliano Zapata (19°27'26"N, 104°57'56"W). 23 July 1995. Marciano Valtierra and Guillermo Nogueira. Museo de Zoologia, Facultad de Ciencias, Universidad Nacional Valtierra and Guillermo (MZFC 7766). Another specimen found in the same area (19°24'59"N, 104°58'33"W). 28 July 1995. Narciso Sandoval. MZFC 7767. Both verified by Fernando Mendoza. These records extend range along the coast ca. 37.5 km (airline) NW of locality in Barra de Navidad (Kofron 1988, Amphibia-Reptilia 9:145–168.).

Submitted by **ANDRES GARCIA** and **MARCIANO VALTIERRA-AZOTLA**, Fundacion Ecologica de Cuixmala, A. C. Avenida Cometa 2910, C.P. 44520, Guadalajara, Jalisco, México.

SONORA SEMIANNULATA (Ground Snake). MÉXICO: BAJA CALIFORNIA SUR: SIERRA DE SAN FRANCISCO: 1 km south of San Francisco de la Sierra, 27°35'12"N, 113°0'59"W. 31 July 1995. Eric Mellink. Verified by Lee Grismer. LACM PC 1323, SVL = 336 mm. Locality lies within the distribution given by Grismer (1994, The Evolutionary and Ecological Biogeography of the Herpetofauna of Baja California and the Sea of Cortes. Doctoral Dissertation. Loma Linda University, Riverside California. 677 pp.), but is the first record from the high reaches of a mid-peninsula Sierra; all other known mid-peninsular localities for this snake are in passes between mountain ranges. The nearest ones are ca. 23 km to the south along the road from San Ignacio to Las Virgenes between the Sierras of San Francisco and San Pedro; the next nearest locality is ca. 172 km to the north between Sierras de la Asamblea and San Borjaa (Grismer, *op. cit.*). Specimen was found at noon, crawling over an open spot, while heading for rock cover.

Submitted by **ERIC MELLINK**, Centro de Investigacion Cientifica y de Educacion Superior de Ensenada, Apartado Postal 2732, Ensenada, Baja California, México.

THAMNOPHIS ELEGANS VAGRANS (Wandering Garter Snake). USA: WYOMING: PARK CO: Shoshone National Forest, between E and W summits of Beartooth Pass, 44°58'40"N, 109°27'10"W on Beartooth Plateau, 10,440 ft (3182 m). 6 July 1998. P. Hendricks and C. Pidgeon. Idaho Museum of Natural History Photofile (IMNHP 001). Verified by Charles R. Peterson. First state record in alpine habitat (Baxter and Stone 1985, Amphibians & Reptiles of Wyoming. Second ed. Publ. Wyoming Fish and Game Dept. 137 pp.; Koch and Peterson 1995, Amphibians and Reptiles of Yellowstone and Grand Teton National Parks. Univ. Utah Press, Salt Lake City. 188 pp.). Adult (38 cm SVL) basking on pocket gopher burrow ca. 500 feet (155 m) above and 1 mi (1.6 km) beyond treeline. Only snake seen in alpine during residency at the pass from 13 July–10 August 1983, 29 June–12 August 1984, 8 June–18 July 1987, 8 June–30 July 1988, 13 June–5 August 1989. Sighting occurred during the hot and dry summer of the nearby Greater Yellowstone Ecosystem fire.

Submitted by **PAUL HENDRICKS**, Montana Natural Heritage Program, 909 Locust Street, Missoula, Montana 59802, USA.

THAMNOPHIS SIRTALIS PARIETALIS (Red-sided Garter Snake). USA: MISSOURI: MACON CO: South 61 Training Area, Missouri National Guard Macon Area Training Site, gravel road along W edge of South 61 Training Area, ca. 3.7 km NW Excello, 39°39'04"N, 92°30'49"W. 27 June 1994. Angelo P. Bufalino. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 5427). Caught on gravel road; new county record (Powell, Johnson, and Parmerlee 1993, Missouri Herpetol. Assoc. Newsl. (6):7–26). Specimen was caught on the western edge of the intergradation zone for *T. s. sirtalis* and *T. s. parietalis* (Johnson 1987, The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City. 368 pp.).

Submitted by **ANGELO P. BUFALINO**, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

New Records for Amphibians and Reptiles from Texas

The following account completes our coverage of the notable new distributional information on the herps of Texas represented in the herpetological collection of West Texas A & M University (WTAMU). First county records are based on Dixon (1987), supplemented by records published in *Herpetological Review*, where our previous contributions derived from WTAMU material have appeared. All identifications were verified by Anthony I. Mazeroll. Adam and Laine Chiszar kindly aided greatly in handling the many hundred specimens examined in our review.

Of special significance are range extensions for *Chrysemys picta bellii, Graptemys kohnii, Pseudemys concinna metteri, Sternotherus odoratus, Cophosaurus t. texanus, Crotalus v. viridis*, and *Nerodia r. rhombifer*. The numerous records for turtles (12 species vs 14 for all other herp species) reflects a long period of emphasis on turtle distribution and natural history by FCK and his students. Most of the WTAMU collection is a product of class efforts over a period in excess of thirty years.

Ambystoma tigrinum tigrinum (Eastern Tiger Salamander). USA: TEXAS: Bell Co: Outside of Belton, near Leon River. 25 October 1994. James H. Kreimeyer. WTAMU 14978-80 (larvae).

Bufo debilis insidior (Western Green Toad). USA: TEXAS: Castro Co: 3.2 km NW Hart, Rt. 168. 19 June 1985. Donita G. Sewell. WTAMU 14603.

Bufo woodhousii woodhousii (Woodhouse's Toad). USA: TEXAS: Nolan Co: Country Club Lake. 14 April 1986. R. L. Cavitt. WTAMU 14952.

Rana sphenocephala utricularia (Southern Leopard Frog). USA: TEXAS: Refugio Co: near Austwell. 16 April 1992. John Shields. WTAMU 14638.

Apalone spinifera guadalupensis (Guadalupe Spiny Softshell). USA: TEXAS: Guadalupe Co: Lake McQueeny. 20 April 1990. Flavius C. Killebrew and Dan Porter. WTAMU 13145.

Chelydra serpentina serpentina (Common Snapping Turtle). USA: TEXAS: Childress Co: Lake Childress, Childress. 24 February 1987. Matt Craig. WTAMU 10766. Gray Co: W of Pampa. 25 June 1966. Robert A. Norman. WTAMU 6.

Chrysemys picta bellii (Western Painted Turtle). USA: TEXAS: Llano Co: Lake Buchanan. April 1981. Flavius C. Killebrew. WTAMU 7417. Possibly complements the nearby isolated and questionable record noted on the distributional map for this species in Conant and Collins (1991). There is no conclusive evidence that any self-sustaining population of the species exists in central Texas.

Chrysemys picta dorsalis (Southern Painted Turtle). USA: TEXAS: Gregg Co: Sabine River near Longview. October 1980. Ichthyology/Entomology classes. WTAMU 6773.

Graptemys kohnii (Mississippi Map Turtle). USA: TEXAS: Hardeman Co: Malcolm Bottoms farm, 4.9 km NW Quanah. 15 August 1982. Fred Kinnaman. WTAMU 8495. Extends the known range about 320 km along the Red River, or 121 km northwest of Throckmorton County.

Kinosternon flavescens flavescens (Yellow Mud Turtle). USA: TEXAS: Crockett Co: 39 km N Ozona. 26 September 1971. Collector not recorded. WTAMU 1169.

Pseudemys concinna metteri (Missouri River Cooter). USA: TEXAS: Grayson Co: Lake Texoma. 5 October 1980. Entomology/Ichthyology classes. WTAMU 6770. Juniper Point, Lake Texoma. 23 September 1983. Flavius C. Killebrew. WTAMU 14976-7. Hansford Co: near Spearman. 8 December 1978. Flavius C. Killebrew. WTAMU 5528. All verified by Anthony I. Mazeroll. A westward range extension of some 500 km in a tributary of the North Canadian River.

Pseudemys texana (Texas River Cooter). USA: TEXAS: Guadalupe Co: Cuero, Guadalupe River. 23 May 1985. Flavius C. Killebrew. WTAMU 10775. Seguin Water Supply Lake. 22 June 1989. Dan Porter and Flavius C. Killebrew. WTAMU 13182. Guadalupe River near San Antonio. 15 March 1984. Collector unknown. WTAMU 13898. Lake Placid. 7 April 1990. K. Brewer and Flavius C. Killebrew. WTAMU 14008-10.

Sternotherus carinatus (Razorback Musk Turtle). USA: TEXAS: Gregg Co: Sabine River near Longview. 1 October 1980. Flavius C. Killebrew and Eric Surat. WTAMU 6182.

Sternotherus odoratus (Common Musk Turtle). USA: TEXAS: Gregg Co: Sabine River near Longview. 2 October 1980. Flavius C. Killebrew. WTAMU 6602. Hardeman Co: Talbert Creek, 8 km S Quanah. 24 November 1981. Fred Kinnaman. WTAMU 7913. Extend the known range about 320 km westward in a Red River tributary.

Terrapene ornata ornata (Ornate Box Turtle). USA: TEXAS: Hardeman Co: dirt road 3.2 km N Rudolph Livingston farm. 21 June 1982. Fred Kinnaman. WTAMU 8479-81. Malcolm Bottoms farm, 4.9 km NW Quanah. 15 August 1982. Fred Kinnaman. WTAMU 8492-5, 8531. Rt. 287 10.13 km E jct. Rt. 6. 18 March 1992. Robyn Richmond. WTAMU 14631. 4.9 km S Rt. 287 10.13 km E jct. Hwy 6. 16 April 1992. Stewart Knight. WTAMU 14974.

Trachemys scripta elegans (Red-eared Slider). USA: TEXAS: Childress Co: Childress Lake, Childress. 24 February 1987. Matt Craig. WTAMU 10767. Donley Co: 14.24 km NW Hedley, Rt. 207. 10 October 1969. K. Brown. WTAMU 2741. Hardeman Co: Rudolph Livingston Farm, Grosbeck Creek. 30 October 1982. Rudolph Livingston. WTAMU 8476. Mills Co: P. K. Caraway Ranch, 5.44 km E jct. Rt. 16 and 3023. 21 April 1977. Dennis

Chance. WTAMU 3235. 22 April 1977. Herpetology Class. WTAMU 3076.

Cophosaurus texanus texanus (Texas Earless Lizard). USA: TEXAS: Aransas Co: Mustang Island. 23 April 1987. Derl Brooks. WTAMU 10280. DeWitt Co: Beard's farm, Schroeder Community, Fannin road. 3 August 1985. T. Foote. WTAMU 13302. A range extension southeastward of ca. 160 km.

Coluber constrictor flaviventris (Eastern Yellowbelly Racer). USA: TEXAS: Moore Co: 0.8 km W Lake Meredith. 28 October 1987. Teresa Smith. WTAMU 13050.

Crotalus atrox (Western Diamondback Rattlesnake). USA: TEXAS: Collingsworth Co: Campbell Ranch, 22.4 km S Wellington. 1 April 1990. Jerry Davis. WTAMU 13585. Parmer Co: Farwell. 17 October 1981. Randy Geries. WTAMU 7326, 7329, 7333-5. Joel McKinney. WTAMU 7087. Roberts Co: Killebrew Ranch. 8 October 1977. Burgi Lehmann. WTAMU 5862. 40 km N Pampa, Rt. 70. 30 September 1989. Derl Brooks. WTAMU 14333.

Crotalus viridis viridis (Prairie Rattlesnake). USA: TEXAS: Foard Co: 11.2 km N Crowell, near old farmhouse. 22 October 1983. Tom Adams. WTAMU 9423-4. Grayson Co: Lake Texoma. 5 October 1980. Ichthyology class. WTAMU 6557. Parmer Co: 27.2 km W Friona, Rt. 2013. 29 April 1929. Tabitha Childs and Gigi Spring. WTAMU 6768. 8 km W and 3.2 km S Bovina, on Rt. 2290. 7 October 1983. Scott Rundell. WTAMU 9467. Extends the known range of the species eastward along the Red River about 160 km.

Elaphe guttata emoryi (Great Plains Rat Snake). USA: TEXAS: Carson Co: Alibates Canyon, Lake Meredith. 21 April 1981. R. Walsh and T. James. WTAMU 6409. Ochiltree Co: Gibner Ranch, 16 km N Spearman on FM 760. 21 August 1978. Flavius C. Killebrew. WTAMU 5587. Scurry Co: 3.22 km S Snyder, Rt. 280. 22 May 1989. D. Porter and M. Craig. WTAMU 14086.

Elaphe obsoleta lindheimerii (Texas Rat Snake). USA: TEXAS: La Salle Co: 41.6 km SE Cotulla. No date, no collector recorded. WTAMU 14325-6.

Nerodia erythrogaster transversa (Blotched Water Snake). USA: TEXAS: Roberts Co: Killebrew Ranch. 8 October 1977. Derl Brooks. WTAMU 3977.

Nerodia rhombifer rhombifer (Diamondback Water Snake). USA: TEXAS: Lavaca Co: 1.6 km W Hallettsville. 11 July 1982. Jay Long. WTAMU 8762. Mills Co: P. K. Caraway Ranch. 23 April 1977. D. Chance and P. K. Caraway. WTAMU 3195. Moore Co: Bonito Creek, Lake Meredith. April 1979. J. Bertl. WTAMU 6481. Potter Co: 14.8 km N Amarillo, FM 1912. 29 April 1972. WTAMU 6549, 6551. 16 km N Amarillo. 29 April 1972. B. Benson. WTAMU 2895. Randall Co: Currie Ranch. 3 October 1981. R. McDowell. WTAMU 7429. A western range extension of about 40 km in the central part of the state panhandle.

Pituophis catenifer sayi (Bullsnake). USA: TEXAS: Gillespie Co: Fredericksburg. June 1987. Dale Brodbeck. WTAMU 11060. Grayson Co: Juniper Point, Lake Texoma. 22 September 1981. Flavius C. Killebrew. WTAMU 8614, 14975.

Thamnophis sirtalis parietalis (Red-sided Garter Snake). USA: TEXAS: Lipscomb Co: 1.6 km S Darrouzett. 1 October 1989. Gene Hay. WTAMU 14336.

Williamson and Moulis (1994) summarized known distributional records of amphibians and reptiles of Georgia. However, comprehensive documentation for many species is still lacking from many counties and several physiographic provinces.

From 7 August 1994 to 30 April 1995, pitfall surveys for shrews (Insectivora: Soricidae) were conducted at ten localities on the Cumberland Plateau, Dade County, Georgia, USA. Sixteen species of amphibians and reptiles were trapped incidentally. Included were four species previously unreported from the Cumberland Plateau of Georgia, which we report on here. All specimens were obtained by Eric Brown and identifications verified by M. E. McGhee and Carlos Camp. All specimens are deposited in the herpetological collections of the University of Georgia Museum of Natural History.

Ambystoma talpoideum (Mole Salamander). Dade Co: Pigeon Mountain Wildlife Management Area, Rape Gap. 14 August 1994. UGAMNH 24865. Fills distribution gap between nearest record in Jackson County, Alabama (Mount 1975), ca. 60 km to the southwest, and nearest record in Bartow County, Georgia (Williamson and Moulis 1994), ca. 85 km to the southeast. To our knowledge, the present record, the single specimen from Bartow County, and five specimens from two localities in Newton County (Williamson and Moulis 1994) are the only records from Georgia north of the Fall Line.

Gastrophryne carolinensis (Eastern Narrowmouth Toad). Dade Co: Pigeon Mountain Wildlife Management Area, Dickson Gulf. 14 August 1994. UGAMNH 24861. Fills distributional gap between nearest locality in Jackson County, Alabama, 35 km to the west (Mount 1975) and Murray, Gordon, and Floyd counties, Georgia, approximately 65 km east and southeast.

Scaphiopus holbrookii holbrookii (Eastern Spadefoot). Dade Co: Pigeon Mountain Wildlife Management Area, Dickson Gulf. 14 August 1994. UGAMNH 24862–24863; Pigeon Mountain Wildlife Management, Rape Gap. 4 February 1995. UGAMNH 24864.

Mount (1975) reported records from the Cumberland Plateau of Jackson County, Alabama, ca. 20 km to the west. Nearest Georgia records are from Whitfield County, 45 km east-southeast (Williamson and Moulis 1994).

Virginia valeriae valeriae (Eastern Earth Snake). DADE CO: Pigeon Mountain Wildlife Management Area, Rape Gap. Two specimens taken, one each on 14 August 1994 and 8 October 1994. UGAMNH 24866–24867. Mount (1975) reported records from the Cumberland Plateau of Jackson County, Alabama, ca 15 km to the west. Nearest Georgia records include Murray County, ca. 70 km to the east, and Floyd County, ca. 85 km south (Williamson and Moulis 1994).

Additional species recovered from the pitfalls include the following: *Bufo americanus, Rana catesbeiana, Aneides aeneus, Eurycea cirrigera, Eurycea lucifuga, Gyrinophilus porphyriticus, Plethodon dorsalis, Plethodon glutinosus, Sceloporus undulatus, Eumeces fasciatus, Carphophis amoenus,* and *Diadophis punctatus*. These species are documented from numerous records in Dade County (Williamson and Moulis 1994) and adjacent regions of the Cumberland Plateau in Alabama (Mount 1975).

The title of this much improved second edition is somewhat misleading, because included are numerous photographs of plants (14), invertebrates (51), and birds (24); and much of the latter half of the book (pp. 353–399) is devoted to mammals and freshwater fishes. Compared to the first edition, which was published in 1992, the coverage is more complete and there are fewer mistakes. However, this second edition is far from error-free, and many of the faults of the first edition are perpetuated, the most important of which are the uneven treatment of amphibians and reptiles and the inclusion of material that will be of no value to most readers (e.g., oscillograms of frog calls) or is otherwise inappropriate for a field guide (formal description of new taxa).

The introductory section includes brief overviews of climate, biogeography, flora and fauna, and conservation issues. Also included in the introduction are three maps indicating the nature reserves in Madagascar, important localities, and biogeographic zones. After the introduction there is a two-page historical overview of herpetological research in Madagascar, which mainly concerns the rate of discovery of new species.

The following systematic sections are unbalanced, in that 36 pages of preliminary information about frogs (characters, measurements, skeletal features, reproductive diversity, egg and tadpole identification) are given, and only two such pages are devoted to reptiles, and even less to mammals and fishes. In addition, Appendix 5 is 23 pages of sonagrams and oscillograms of frog calls. This frog bias, indicated also by the beautiful cover photo of a *Boophis luteus*, undoubtedly reflects the interests of the authors, both of whom are pursuing Ph.D.s in programs centered around frog biology and systematics.

The sections that include the species accounts also give short summaries for each family and genus. Keys or determination tables are present for genera and species. Species accounts of frogs include subheadings for distribution, description, habits, call, eggs and tadpoles, and similar species. The reptile accounts are much abbreviated and contain no subheadings other than a diminutive "Distribution:" at the beginning of most accounts. For both frogs and reptiles, with a few exceptions (e.g., *Hemidactylus*), known specific localities and references documenting the localities are listed. Range maps are presented for most species, which consist of small outline maps of Madagascar with type localities indicated by a star and other localities by a dot. The distributions of a few reptiles are indicated by shading rather than dots, and in these cases the type localities are not indicated, perhaps because they are unknown. No reason is given for this deviation from dot maps. The maps are either placed individually near the corresponding species account (frogs) or are grouped (up to 20 maps) on a single page placed reasonably close to the relevant species accounts (reptiles and other groups).

Four new subgenera of *Mantidactylus* are described in the guide along with 11 new species and 2 new subspecies of frogs (*Boophis* and *Mantidactylus*). Additional taxonomic changes include elevation of *Boophis sibilans* (formerly a subspecies of *B. albipunctatus*) to species rank, resurrection of *Mantella cowani* and *Mantella pulchra* from synonymy of *Mantella madagascariensis* (these resurrections were already generally recognized), and rearrangement of various species groups of frogs. The authors also designate several frog lectotypes. No new reptile taxa are named, but *Lygodactylus septemtuberculatus* is placed in the synonymy of *L. miops* and *Calumma hilleniusi* is elevated from a subspecies of *C. brevicornis* to species rank. *Furcifer balteatus* is transferred from the *Calumma parsoni*-group to the *Furcifer bifidus*-group, the *Calumma boettgeri*-group is disbanded and placed within the *Calumma nasuta*-group, and informal species groups of *Brookesia* and Madagascan *Phelsuma* are named.

A 30-page section on mammals follows the reptile accounts. The mammal species accounts are short and limited to brief descriptions and notes on distribution, habitats, and status. Most of the distribution maps for lemurs consist of shaded areas rather than dots, but dot maps are used for the remaining mammals (carnivores, bats, tenrecs, shrews, rodents). Type localities are not indicated on the maps. In addition to several black-and-white photographs of mammals, there are 61 color plates, mostly of lemurs, some of them mislabeled according to a list of errata on p. 7.

After mammals there is a 19-page section on freshwater fishes which includes keys to families, cichlids, cyprinodonts, *Rheocles*, and eleotrids. In addition to very brief accounts of families and some species, there is a short section on introduced species and a list of marine families and species known to enter freshwater habi-

tats of Madagascar. A few black-and-white and 15 color photographs of fishes are included. No range maps are given for fishes.

Seven appendices follow the accounts of fishes. The first includes descriptions of four new subgenera of *Mantidactylus*. The second summarizes taxonomic changes published elsewhere and in the field guide since 1992 when the first edition was published. The third appendix is a summary of the field guide in English, German, and French and includes mainly a description of the taxonomic changes and new information that is presented. The fourth, which is mislabeled "Appendix 3," is a list of species and subspecies of amphibians and reptiles of Madagascar, including the original name and author, date of publication, type locality, museum where the types reside, and the current name. The fifth appendix is a set of 119 sonagrams and 126 oscillograms of frog calls. The sixth is a list of references grouped into sections on amphibians and reptiles (598 references), mammals (182), fishes (69), other groups (39), and personal communications (11); each reference is numbered and arranged alphabetically by author and date. The seventh is a gazetteer of localities and a locator grid-map (each grid cell being 0.5° x 0.5°), which includes six pages of about 600 localities listed alphabetically. Unfortunately, the page headings for Appendix 7 read "Appendix 6: references," an obvious printing error.

Following the appendices is a systematic index to all species, indicating the page number of the account, and, where relevant, the number of the color plate or figure pertaining to the species.

The book is attractively produced on good quality, 100% recycled paper in the same size and format as the first edition. However the binding is extremely fragile, and certainly will not survive long under field conditions. The printing quality, while generally good, is unclear or faint in places (usually only two or three words are affected). The traces in some of the sonagrams are barely visible. The standard text print is rather small, and the print size in the keys, determination tables, sections documenting localities of reptiles, and some of the maps is irritatingly small, especially in dim light. Elderly users and visually impaired readers will have trouble reading these sections.

Given that English is not the first language of either author, the text is remarkably free of grammatical and spelling errors and is eminently readable, even delightful in places. That is not to say the text is error-free; some typos and/or syntax anomalies occur, but in large these errors are not distracting.

Other errors of significance occur, however, and these are numerous enough that the authors (Glaw, in litt.) are planning to produce a supplement which will include a large set of errata and perhaps some new information. The errors include mislabeling or misnumbering of photographs and color plates, misplaced dots on range maps, missing information that was readily available in the literature and in museums, and errors of fact in the text.

The book is reasonably well organized and easy to use. The species accounts are condensed and standardized, deviating from form only when a new frog species is described. References to literature in the text are indicated by numbers in brackets that correspond to a citation in Appendix 6. Three improvements in organization would have been to place the distribution maps of the reptiles next to the corresponding species accounts, as was done with the frogs; closer positioning of photographs and species accounts; and an alphabetical arrangement of supraspecific taxa in the accounts.

The introductory material is useful but rather vague in places. For example, in a section on climate, the authors indicate that Madagascar is usually subdivided into Domains based largely on climate, but they give no citations for the climatic data nor any indication of who first proposed the Domains. Their discussion of biogeography is brief and non-illuminating. It is not very useful to say that the "distribution patterns of amphibians and reptiles" are "roughly in agreement" with the climatic domains. The authors indicated (p. 14) that biogeographic "zonation" (Domains ?) would be referred to in the distribution sections of the species accounts, but we found no such references in the accounts. In effect, there is no biogeographic analysis of amphibians and reptiles in the guide. The reviews of the historical geology and the origin and character of the fauna and flora of Madagascar in the Introduction are interesting but unbalanced and not properly documented. No references are given for the too brief section on historical geology, and many of the statements of fact about the biotae are unreferenced. The numerous photographs of plants, invertebrates, and birds in the Introduction will be of only passing interest to herpetologists and distracting to some readers. The section on conservation is packed with valuable information, but again, too few references. How, for example, do the authors know that 50% of the rain forest in Madagascar was destroyed between 1950 and 1985? The authors discuss exploitation of species popular in the pet trade, but give no press to the numerous, poorly known species that are known from only one or few specimens, some of which haven't been seen in decades.

The authors consider their book a field-guide, and four sources of information are provided for species determination: species descriptions, illustrations, character determination tables, and keys. However, many genera are not completely illustrated or lack character tables, and the largest herpetological genus in Madagascar, *Mantidactylus* (56 species), has no identification key. Sonagrams and oscillograms are also provided for many amphibian species, although it seems unlikely that most readers will ever use them to aid species identification.

The amphibian keys use a combination of characters which are either almost impossible to determine on live frogs (e.g., webbing formula, tympanum/eye ratio, tibiotarsal articulation point, vomerine teeth), or require live frogs (e.g., coloration characters that do not preserve in fixative and call characteristics). Therefore using these keys will sometimes require recording calling males (during a breeding period which may be short), photography of natural coloration, and preparation of museum specimens.

The keys themselves do not appear to have been carefully checked against the determination tables, resulting in discrepancies. As an example, for the frog genus *Boophis*, the finger webbing formula used in the first key couplet requires that *Boophis tephraeomystax, B. microtis,* and *B. opisthodon* do not have external finger webbing 3e(0-2), but the determination table describes these species as having finger webbing 3e(1). Discrepancies also exist between the species descriptions and determination table, and the species descriptions and the identification key. For example, the foot webbing of *Boophis tephraeomystax* is either 4i(1) in the description, or absent in the determination table. Other *Boophis* species, such as *B. microtympanum, B. laurenti*, and *B. williamsi*, are described in the species descriptions as having a "trace of webbing between fingers 3 and 4," but if the reader chooses the first key couplet condition "no or nearly no webbing between the external fingers" correct identification is impossible using this key. These types of errors make species identification time consuming, extremely frustrating, and considerably increase the risk of misidentification.

Because there is no *Mantidactylus* key, the determination table for this genus provides the main method for species identification. However, many of the most difficult species can not be identified using this table alone such as *Mantidactylus aerumnalis*

and *M. opiparis; M. curtus, M. ulcerosus, M. alutus,* and *M. biporus; M. eiselti* and *M. thelenae; M. asper* and *M. spinifer; M. luteus* and *M. plicifer; M. tornieri* and *M. depressiceps*. The species descriptions usually provide further information under the section "similar species"—but not always, and some of the most difficult groups of frogs cannot be identified using this guide. For example, on page 129 we are told that species determination for the *M. wittei* complex "is very difficult, if not impossible," and "very difficult" for the subgenus *Brygoomantis* (page 167). For this latter group of frogs, the authors have opted to present the work of previous researchers, rather than deal with these significant identification problems. Ironically, although the main focus of this second edition is still amphibian identification, we suspect that most readers are going to have major difficulties when trying to use this book, both in the field and in a museum environment.

For the reptiles, because the species descriptions are so short, and many species are not well illustrated, identification is heavily dependent on using keys. Most of these keys have been taken from the literature, and typically use characters based on preserved museum material. However, original keys have also been included for some groups such as *Amphiglossus, Lygodactylus*, and *Phelsuma*. These new keys provide a valuable summary of a diverse literature, but suffer somewhat from the poor choice of characters. In the *Phelsuma* key, the first couplet uses characters (femoral pore counts and total length measurements) that are not shown by females, juveniles, or individuals with damaged or regenerating tails; while in the *Amphiglossus* key the first couplet character requires either a skeletal preparation or x-ray examination (to make a presacral vertebrae count). This poor choice of characters means that accurate field identification of many of the reptile groups will be extremely difficult using the keys in this guide.

Although the range maps are useful, they must be viewed with caution, because, according to the authors, most localities are taken from the literature and the identifications of the voucher specimens usually were not verified. The confusion of collecting sites that exist in the literature will also contribute significant errors to some of these distribution maps (many Malagasy localities share identical or very similar names). In addition, we already know these maps are very incomplete, based on the large number of new distribution records that the Zoology Department (University of Antananarivo), and the Museum of Zoology (University of Michigan) have been accumulating since 1989.

The quality of the figures and color plates is highly variable. Most of the color plates are good to exceptionally good, but there are poor ones, and many of the black-and-whites are of poor quality. A large portion of the photographs were borrowed and acknowledged, and a significant number of them are mislabeled or misreferenced. For examples, color plate 176, referenced on p. 235 as *Brookesia nasus* and labeled the same, is actually a photograph of an African *Rhampholeon*; Fig. 504 is labeled *Liopholidophis lateralis,* but is actually *L. stumpffi*; Figs. 508 and 509 are referenced on p. 343 as "*Stenophis* sp. 2 Domergue, in press," but 508 is a black and white of *Ithycyphus oursi* and 509 is *Stenophis betsileanus*, both properly labeled. Most of the key illustrations are reproduced from other works, and the quality of reproduction is good to poor. An example of poor quality key illustrations are those of the chameleons taken from Brygoo's monographs.

The usefulness of the sections on mammals and freshwater fishes is questionable because of their brevity, and the authors admit that these sections will never compete with field guides devoted to these subjects (at the same time as Glaw and Vences guide was published, an excellent guide to the lemurs was published by Mittermeier et al. 1994). The authors included these sections as a "service," but they will only service those owners who can't afford other literature or who are only very generally interested in the vertebrate fauna of Madagascar. Most herpetologists probably would have preferred that the space be used for expanded and more detailed accounts of the herpetofauna, especially the reptiles. The two most popular groups, and also those most likely to be seen by visitors, are the chameleons and the day geckos. And yet the quality of the photographs and information presented about these diurnal reptiles does not measure up to that given for frogs, the group which includes the greatest number of species that are unlikely to be encountered by visitors.

The authors have done professional herpetologists a service by providing details of frog reproductive biology, sonagrams (Appendix 5), and information regarding original and current names (Appendix "3" = 4), however, this extra material will probably never be used by the average owner of this guide. Professionals will also find the gazetteer in Appendix 7 of use, but, for the precision needed in scientific work, it will still be necessary to use maps, GPS devices, and more detailed Madagascar gazetteers such as the one published by the United States Board on Geographic Names (1989) which includes 35,000 localities with coordinates.

It is a bit startling to see the publication of new subgenera, species, and subspecies in a field guide, especially one that is privately published by the authors. Glaw and Vences seem to be aware of the controversial nature of describing new taxa in privately published and unreviewed books and journals as they attempt to justify their actions in the Introduction. Many of the new species discovered in Madagascar (by Glaw, Vences, and others) have been recently described either in non-technical, non-peer reviewed, pet-keeping magazines; non-peer reviewed amateur journals; or journals with a very limited peer review process. The advantages of such sources for publication are obvious: rapid publication, and without the burden of having to convince reviewers that the newly described taxa are valid. For example, many professional journals would probably not accept papers describing new subgenera in the manner of those established for *Mantidactylus* by Glaw and Vences in their field guide, because they presented no evidence that these groups form monophyletic clades. Their diagnoses (Appendix 1) are purely phenetic and include ecological data, conditions which almost assure paraphyly in large groups such as *Mantidactylus*. Furthermore, it appears they rather uncritically accepted information from the literature in defining these taxa and may not have verified the diagnostic characters for every included species. Given the primitive state of systematics of Madagascan frogs, establishment of these four subgenera of *Mantidactylus*, and the additional seven by Dubois (1992), seems premature, and will likely cause confusion later on. Furthermore, the formal naming of subgenera (why not use informal species-groups?) serves no real purpose other than perhaps assuring authorship should it ever be decided that the subgenera, or parts of them, deserve generic rank.

The authors mentioned that Boulenger is the champion among the early describers of Madagascan frogs in the sense that he has the highest number of named species that are still valid. Glaw and Vences would do well to take a lesson from their own writings. History will judge them not by how many taxa they have described, but by the quality of their work and how well it stands the test of time.

Other than the changes mentioned above, the field guide generally follows the nomenclature of recent revisions and is up-to-date. Two exceptions are the unexplained decision not to use the name Opluridae (Frost and Etheridge 1989) for the Madagascan

iguanians, and their rejection of the modification of boine snake classification presented by Kluge (1991), in which *Acrantophis* and *Sanzinia* are placed in the synonymy of *Boa*. Glaw and Vences's reasons to reject Kluge's classification, by making a comparison to iguanian classification, and claiming that changing the taxonomy would cause confusion in the "worldwide conservation administration" are not convincing, and probably reflect Glaw and Vences's disregard for cladistic principles, as is suggested by their naming of phenetic subgenera.

As Glaw and Vences wrote in the preface, if they were typically German (like Helmut and Kurt, two German students with whom Glaw and Vences draw comparisons to themselves), and waited until the knowledge of the Madagascan herpetofauna was complete before attempting to produce such a book, they would never have been able to start. Perhaps more than anyone else, Glaw and Vences are acutely aware of the limitations of their field guide.

Despite the errors, unbalanced subject matter, uneven quality of figures, problems using the guide to identify species, the questionable procedure of taxonomic revision in an unreviewed and privately published book, incompleteness, and its almost immediate antiquation (many more species of amphibians and reptiles will certainly be described over the next few years), this is a useful book, and the authors are to be admired for the enormous amount of work that went into its production.

In many areas of the New World tropics, snakes in the genus *Chironius* are among the most abundant diurnal snakes. Nevertheless, for field herpetologists, they can be among the most difficult to find and once found, they can be even more difficult to capture. Because many localities contain several species, all of which appear superficially identical, capture and scale counting is the only way to confirm identification and in some instances that even fails given the available keys prior to Dixon et al. I have always viewed these snakes as herpetologist watchers, as they most certainly capture and integrate images of every continuously moving object in their field of vision. If the object is not food, the snakes slide away, equally agile on ground or in vegetation. I suspect that a vast majority of individuals are never seen simply because they have detected the presence of a herpetologist (clearly not differentiating "herpetologist" from all the other potentially threatening moving objects) long before the herpetologist is within his/her own snake detection range. Luckily for persistent herpetologists, the headlight is not part of the evolutionary history of *Chironius*. Consequently, as they sleep on vegetation, having been convinced by their evolutionary past that they are safe from most predators, they can easily be detected and captured. A vast majority of *Chironius* that I have found were captured at night and I have always been amazed at how "rare" they appear to be during the day.

In their revision of the genus *Chironius*, Dixon et al. begin by carefully reviewing the history of the genus name and the confusion in early literature. Linnaeus (1758) first described three of the currently recognized species under the genus *Coluber*. Even though the genus name *Chironius* was first used in 1826 by Fitzinger, it was not until the 1920s that *Chironius* became widely used. The authors recognize 20 taxa.

Twenty tables of morphological data precede species accounts providing the basis for what follows. The amount of work that went into compiling and summarizing those data, based on examination of 2978 specimens, is simply overwhelming. Whether one agrees or not with Dixon et al.'s taxonomy, the data are made available for all future workers in a concise and clear format. Furthermore, where significant variation exists within taxa, additional tabular data are provided so that the reader has access to data on which taxonomic decisions were based.

The key is straight forward and relatively easy to use as snake keys go. The authors have carefully avoided using color characters for those species in which there is geographic or ontogenetic variation and this should reduce confusion and hopefully will force non specialists to work their way through the keys rather than guessing identity based on color and pattern.

Chironius fuscus from the Rio Xingu, approximately 60 km SE Altamira, Pará, Brazil (1987). Photo by L. J. Vitt.

Following the tables and key are systematic accounts, first for each species and where applicable, with subspecies embedded. The systematic accounts are thorough, following standard format and including figures of relevant taxonomic characters (e.g., hemipenes, color patterns) and black and white photographs where appropriate. The distribution maps are spot locality maps so we

know where the material for descriptions was collected. Each account describes in detail variation that has been observed in the specimens examined providing the reader the opportunity to make critical identification decisions when key characters are ambiguous.

The life history accounts for each species provide an incredible amount of useful information that typically does not appear in taxonomic accounts and demonstrates how much data can be collected from individual museum specimens. We learn that *Chironius* are primarily frog eaters, and indeed, most of their diet consists of typically nocturnal species (hylids, leptodactylids, the lizard *Hemidactylus mabouia*). The important point is that the assemblage of natural history data compiled in this publication has the potential to generate numerous testable hypotheses about the ecology and behavior of these fascinating snakes. The data themselves suggest interesting questions that would not be asked otherwise. As environments throughout the world are being heavily impacted by man our only ammunition is real data on the organisms that comprise biodiversity on a local level. Lack of this information as development decisions are being made is akin to building a legal defense with no evidence.

Also within the life history accounts are behavioral observations that not only are extremely accurate but also suggest numerous hypotheses that could spawn additional research. We even learn the ecto and endo parasites to which these snakes are hosts.

The life history accounts clearly showcase the value of museum specimens in general (see also Greene 1986, 1994). With modern comparative methods (e.g., Harvey and Pagel 1991; Brooks and McLennan 1991) one could potentially reconstruct the evolutionary history of diet, reproductive characteristics (e.g., clutch and egg size), or examine the coevolution of host and parasites in *Chironius* (given a well supported phylogeny).

In the character summary on p. 24, Dixon et al. argue that the large eyes (and presumably keen eyesight) are adaptations for finding frogs and other prey that move "quickly and erratically." An alternative hypothesis is that large eyes and keen eyesight (which must have evolved early in the lineage) originally arose as an adaptation to detect and escape from predators and secondarily serves well for capturing fast moving prey. The data presented on diet suggest to me that *Chironius* are searching for prey that are typically inactive during the day and adds credence to the alternative notion that large eyes and keen vision may have arisen for predator avoidance rather than prey capture. As more diet data are collected and analyzed, it may be possible to test these competing hypotheses by examining the topology of diets on an independently derived cladogram for the genus.

The discussion of interspecific relationships and zoogeography (some 35 pages) is fascinating and should catch the attention of researchers working with a variety of organisms. Dixon et al. construct a phylogeny based on shared derived morphological characters, which, by their own admission, is only as good as the quality of the characters. It was not entirely clear to me why the phylogeny was constructed "by hand," given the numerous cladistic analyses packages available (e.g., *PAUP*, Swofford 1991; *MacClade*, Maddison and Maddison 1992). They then review Cenozoic history concentrating on Central and South America to set the stage for an interpretation of the historical zoogeography of *Chironius*. On page 222, Dixon et al. present the earlier phylogenetic hypothesis against a geological time frame and support their construct with published data on the history of the Amazon and surrounding regions. The authors indicate that their scenario is speculative, which is of course clear in reading it. However, the historical scenarios are interesting in themselves, and if taken as potentially testable hypotheses, should serve well to generate further discussion and research. Some alternative hypotheses are not considered, and I refer the reader to the section on zoogeography (p. 599) of the recent book on Amazonian lizards by Avila-Pires (1995) for an insightful discussion of these.

A brief summary of taxonomic changes makes it easy for the reader to determine what is new and two appendices, one of specimens not examined, the other of specimens examined, will direct interested systematists to the material on which this study was based.

At the end of the book is a series of color plates which, when coupled with the fact that no other tropical snakes have 10 or 12 dorsal scale rows, should make it ridiculously easy for anyone to immediately determine whether or not the snake that is chewing up their arm is a *Chironius* (as opposed to a *Philodryas*, for example!). More importantly, the color variation shown for all of the *Chironius* for which photographs were used clearly indicates the importance of key morphological characters in the identification of these snakes.

Overall, the errors and ambiguities are minimal and easily resolved. Tables are at first confusing because subspecies are listed in alphabetical order without the abbreviation for the genus, or, when subspecies exist, spelling out of the specific epithet. The reader has to turn to species accounts to determine which are species and which are subspecies. For example, under *monticola* are *m. cochranae, m. foveatus, m. multiventris,* and *m. septentrionalis,* in that order. In fact, *m. cochranae, m. foveatus, m. multiventris* and *m. septentrionalis* are subspecies of *C. multiventris,* not of *C. monticola.* More careful formatting in the first table could have avoided this confusion.

The word "oviducal" is used incorrectly throughout for "oviductal." This error somehow entered the life history literature prior to 1970 and still appears in some papers published by major scientific journals. "Oviductal" refers to things (usually eggs) in the oviduct, there is no structure called an "oviduc" (Smith et al. 1989).

In the *Definition* of the genus *Chironius* on p. 19, I would have added the descriptor "thin-bodied" or "streamlined" as all members of the genus are exactly that. Even the *Description* on the same page fails to mention the fact that all species are long and slender. Indeed, it is not until p 236 that we learn that these snakes have "...attenuated bodies, relatively long tails...."

Not all frog names are up to date. For example, "*Hyla rubra*" is now *Scinax rubra* (Duellman and Wiens 1992).

Color plates are not listed in the Table of Contents.

The use of quotes with periods and commas is incorrect throughout. Terminal quotes belong outside of the periods or commas, not inside, regardless of whether the periods or commas are part of the quote (Anonymous 1972, p. 39).

I have no doubt this will be a classic and should be on the shelves of all serious herpetologists working in the tropics. The combination of detailed species accounts, accurate distribution maps, discussion of variation, and summaries of morphological and life history data make this a particularly thorough and valuable contribution to tropical herpetology. Systematists can feel comfortable identifying their specimens (if the authors haven't already done their work for them), cladists can play with the data and possibly combine them with molecular characters, and ecologists and behaviorists interested in these snakes should not be bogged down with identification problems if this book is used properly. Moreover, the zoogeography section contains enough testable ideas to keep biogeographers interested in snake evolution busy for years to come. This is a "must buy" book for any serious tropical herpetologist.

This volume serves as a review of the integumentary system of amphibians. It will be the first volume in a series to deal with various aspects of amphibian biology in a corollary fashion to *Biology of the Reptilia*.

The preface to the series by Harold Heatwole reviews past and present attempts at reviewing amphibian biology and correctly recognizes a gap in both coverage and currency. The clear comprehensive coverage of Moore's *Physiology of the Amphibia* stood as foundation for reviewing the literature and delineating significant gaps in our understanding. These various volumes are now 20–30 years out of date.

The preface to volume 1 by Heatwole and George Barthalmus delineates the unique position the amphibian integument plays in their biology. Besides interfacing in mechanical ways with the environment there are significant mass fluxes of gases, water, and salts. In conjunction there are numerous glands with a plethora of chemicals unmatched in any vertebrate group.

Chapter 1 by Harold Fox nominally covers the structure of the integument. In reality, most of the chapter deals with aspects of development of the dermis and epidermis. The chapter is short. Fox has already published a series of reviews on the amphibian integument throughout the 1980's and this chapter is an update of those reviews. I feel this is a shortcoming since a comprehensive review is not present in this chapter.

Chapter 2 by Michael Warburg, Dina Lewinson, and Mira Rosenberg nominally covers the ontogenesis of the amphibian integument. The actual coverage is an in-depth analysis of larval-metamorphic changes in two species, *Pelobates syriacus* and *Salamandra salamandra*. The chapter is well written and reasonably well illustrated. The micrographs are clear though not crisp.

Chapter 3 by Sally Frost-Mason, Randall Morrison, and Kenneth Mason covers pigmentation. There is a major emphasis on development and biochemistry of the pigments. There is an attempt to correlate structure and function but with little regard for the work of others. For instance the discussion of chromatophore units in *Hyla* fails to acknowledge the contributions of Hans Nielsen in this genus. There is no synthesis of the biologic role of color in amphibians.

Chapter 4 by Uri Katz and Wolfram Nagel is on the biophysics of ion transport across the skin. Unlike the preceding three chapters there is no attempt to deal with developmental or ontogenetic changes. The authors are clear that this chapter is not a comprehensive review and provide references for those interested. A lucid, organized presentation of both sodium and chloride transport is presented. I was left wanting more on the regulation of these transport processes.

Chapter 5 by Dan Stiffler is on the role of cutaneous acid-base electrolyte exchange in organismic pH regulation. This is a narrow topic, but the information presented is comprehensive and state of the art. There is a consistent attempt to deal with mechanism and control.

Chapter 6 by Bob Parsons is on the effects of skin circulation on water exchange. Again a narrow but significant topic given the role of the skin in water uptake. The chapter is well written and provides a comprehensive picture with regulation as a unifying perspective.

Chapter 7 by Gary Malvin is on the cardiovascular regulation of cutaneous gas exchange. The topic is narrow, the review focussed, and regulation is emphasized. There is an excellent balance of theory and data.

Chapter 8 by David Booth deals with the effect of unstirred layers on gas exchange. Unstirred boundary layers develop around the surface of any object in a fluid. Whether they significantly influence cutaneous gas exchange or impact the biology of amphibians is still conjectural. The chapter is well written and provides a good theoretic framework.

Chapter 9 by Vittorio Erspamer is on bioactive secretions. This chapter is the foundation and tour de force of the book. The chapter represents 40% of the book and contributes to the decision to dedicate the whole volume to Dr. Erspamer. The chapter is a fascinating compilation of the biogenic amines, bioactive peptides and alkaloids found in amphibian skin. The characterization, phylogenetic distribution and physiologic effects of these substances on a variety of preparations are presented. This chapter alone would make the book a worthwhile reference. The potential evolutionary and ecological questions this synthesis opens up are exciting.

Chapter 10 by Lynne Houck and David Sever is on the role of skin in reproduction and behavior. This chapter represents the nominal bridge to the second volume of this series on social behavior. The emphasis of this chapter is on how integumentary structures interface with behavior to impact reproductive success and then how their phyletic distribution can be used to infer their evolution. The role of pheromones and chemical signals in reproductive behavior, territorial interactions and as anti-predator events are comprehensively reviewed. I very much enjoyed the synthetic attempt to cover various levels of biologic organization in this chapter.

Chapter 11 by George Barthalmus is on the biologic roles of skin secretions. The actual coverage is an analysis of skin glands in *Xenopus* as they relate to predatory defense, microbial defense and reproduction. Though the focus is narrow and not reflective of the title, the data are interesting and well presented.

The book suffers from a major flaw, there are significant gaps in the topics covered. A book whose aim is to be the definitive reference on the amphibian integument and not deal with topics like the regulation of and differences in the rate of water exchange across the integument seems very myopic. Some of the most significant discoveries in amphibian integumentary biology, like reduced evaporative water loss in certain arboreal species, are not mentioned or described. This is an editorial decision and not the responsibility of the authors. Couple this to the titles of many chapters not reflecting the narrow perspective presented indicate to me an abdication of editorial responsibility of a volume whose goal is to rival *Biology of the Reptilia*.

Despite the narrow perspective of many chapters and the gaps in topic coverage, what is presented is first rate and professional. The book will serve as an excellent reference for the topics covered. Whether every biologist interested in amphibians will need a personal copy is problematic. Clearly this volume should be in every school's research library.

Pleistocene Amphibians and Reptiles in North America, by J. Alan Holman. 1995. Oxford University Press, New York, and Clarendon Press, London. 243 pp. Hardcover. US $65.00. ISBN 0-19-508610-4.

JAMES D. GARDNER
Department of Biological Sciences and
Laboratory for Vertebrate Paleontology
University of Alberta, Edmonton, Alberta, T6G 2E9 Canada

With its climatic fluctuations and alternating glacial and interglacial episodes, the Pleistocene Epoch surely qualified as a time of environmental crisis. In North America numerous genera and some families of large mammals went extinct during this interval (e.g., Martin 1984), as did many genera of birds (e.g., Steadman and Martin 1984). The fate of amphibians and reptiles during the Pleistocene, however, is less well-appreciated. *Pleistocene Amphibians and Reptiles in North America*, the first comprehensive treatment of North American Pleistocene herpetofaunas, attempts to address this situation. J. Alan Holman is well-qualified to tackle such a project, because since the late 1950's he has been actively involved in the study of North American Cenozoic herpetofaunas.

The main body of this book consists of eight chapters. Following the brief introductory chapter (pp. 3–4), chapters two (pp. 5–20) and three (pp. 21–28) summarize, respectively, the North American Pleistocene and history of the North American pre-Pleistocene herpetofauna, from the Late Cretaceous to Pliocene. Although some might question the relevance of pre-Pleistocene amphibians and reptiles in a book devoted explicitly to Pleistocene herpetofaunas, I applaud Holman's desire to present the latter in an historical context. All too frequently we tend to view populations or taxa in isolation, forgetting that they are part of an historical continuum.

Chapter Four (pp. 29–81) is an annotated, systematic checklist of the 230 nominal species of North American Pleistocene amphibians and reptiles. Familial and generic accounts are concise; each briefly describes the general appearance, habitats, and geographic range of extant members in North America. Abbreviated, generalized osteological diagnoses are also presented for each family. Accounts are complemented by illustrations of 43 extant species with Pleistocene records.

Our understanding and interpretations of taxa known as fossils depend absolutely on our ability to reliably identify these taxa. It is thus fitting that the fifth chapter (pp. 82–98) briefly describes the skeletal elements that are commonly used to identify Pleistocene amphibian and reptilian taxa (e.g., ilia for anurans and trunk vertebrae for snakes) and each of these element's taxonomically more useful attributes. Descriptions in this chapter are illustrative; persons seeking detailed osteological diagnoses for particular taxa will have to delve into the primary literature. Illustrations of bones from 53 species with Pleistocene occurrences depict all of the key features reviewed in this chapter. Holman repeatedly advises would-be Pleistocene paleoherpetologists to make extensive use of comparative extant collections and develop an appreciation for patterns of variation within and among taxa. This advice is applicable to systematists in general, regardless of their group(s) of interest.

Chapter Six (pp. 99–179) is the core of this volume: it reviews 170 Pleistocene sites (three in Canada; the remainder in the lower 48 states), grouped under eight geographical regions, that have yielded amphibian or reptilian fossils. Accounts for each site include a brief description of its location and sedimentology, inferred depositional environment and age, and relevant comments and references. Accounts for more important sites—e.g., typically those with diverse faunas—also include a faunal list. Each regional section ends with a systematic checklist of its known Pleistocene species, cross-referenced by sites. This summary of known North American Pleistocene herpetofaunas will be useful to (and welcomed by) workers in many fields.

Chapter Seven (pp. 180–199) compares region-by-region how, if at all, the geographic ranges of amphibians and reptiles changed through the Pleistocene. Chapter Eight (200–211) first assesses the validity of the 17 nominal species and three nominal subspecies of currently recognized North American Pleistocene amphibians and reptiles (Holman concludes that 12 species and two subspecies are valid), then examines patterns of extinctions. To my knowledge, there is nothing particularly revolutionary nor contentious in either of these interpretive chapters. Compared to large mammals and birds, North American Pleistocene herpetofaunas were surprisingly stable, with only about 5.4% of species becoming extinct. Further, herpetofaunas in unglaciated areas also tended to stay put, suggesting that taxa readily adapted to long term climatic changes and associated biotic perturbations. Holman summarizes contemporary explanations for the stability of the North American Pleistocene herpetofauna, but he does not commit himself to any one theory. As he sagely observes, until we acquire a deeper understanding of how modern amphibians and reptiles respond to environmental changes, our explanations for the resiliency of the North American Pleistocene herpetofauna will remain speculative.

Given Holman's recent work on Pleistocene amphibians and reptiles from Europe (e.g., Holman 1992, 1993; Holman et al. 1990), I was surprised that he did not take the opportunity to compare the Pleistocene herpetofaunas of North America and Europe. If such comparisons are feasible they may prove most interesting, because the timing and rates of extinction between Pleistocene mammals on the two continents show intriguing differences (Martin 1984).

A reference list of 265 articles, followed by general, site, and taxonomic indices complete this book. Unfortunately, the general index appears to belong, at least in part, to a different book.

In total, 43 pen-and-ink drawings are presented: five of these are maps; the remainder depict extant species and bones from species with known Pleistocene occurrences. About one-quarter of the species reported from the Pleistocene, including most holotypes of Pleistocene species, are figured. Most of the figures in this book have been taken from other published sources and, thus, are of varying styles and quality.

Holman's goal in *Pleistocene Amphibians and Reptiles in North America* is to examine "the Pleistocene amphibians and reptiles of the North American continent (excluding Mexico) with emphasis on their ecological relationships and patterns of evolution and extinction" (p. 4). Holman has also directed his book at a more general scientific audience. Within these parameters, I feel that Holman's book adequately accomplishes its objectives. Aside from some typographical errors and the above-mentioned problem with the general index (surely the publisher's blunder), I have only one concern about this book. Although I can sympathize with the dilemma of trying to present a balanced account satisfactory to both specialists and novices, I feel that in some instances Holman catered to the latter audience too much. Specifically, some discussions were overly simplified and supporting documentation was often sparse. For example, in the overview of the North American pre-Pleistocene herpetofauna several fossil taxa were omitted (e.g., the extinct Albanerpetontidae and the enigmatic latest Cretaceous frog *Theatonius*). Further, although several papers (e.g., Tihen 1964; Estes 1970; Hutchison 1992) are relevant to the discussion in Chapter Three, Holman cited only Estes and Baez's (1985) paper. Such sparse documentation is annoying, because it needlessly complicates the task of tracking down pertinent references. I must temper my comments at this point, by acknowledging that this book alerted me to several papers, relevant to my own work, of which I was previously unaware.

In conclusion, I was generally pleased with *Pleistocene Amphibians and Reptiles in North America*. This book is an up-to-date, readily accessible summary of our current understanding of North American Pleistocene herpetofaunas. As such, it stands as both an invaluable reference and a source of potential ideas for future research.

LANI LYMAN-HENLEY

Division of Science & Mathematics, Mississippi University for Women Columbus, Mississippi 39701, USA

Despite the growing popularity of snakes as pets, there is a definite shortage of books dealing with the husbandry of native species. Much of the information available to people interested in keeping snakes—whether professionally or as interested laypersons—deals with a few well-known types (e.g., corn snakes) or exotics (e.g., pythons). With this problem in mind, I recommend this book to anyone interested in the husbandry of native snakes of western North America, be they laboratory researchers or mothers dealing with the snake Junior insists on bringing home. This book contains a wealth of information and is a worthwhile book for herpetoculture. However, with that "bottom line" assessment, there are a great many (mostly minor) flaws that I hope can be remedied in later editions.

One theme raised frequently in this book concerns the herpetoculture of native species as a means of preservation and building a knowledge base. The authors rightly point out that methods that work for four or five well-known genera don't necessarily apply to the other 50. The argument is brought up in favor of keeping various native species, including the less flashy ones, since the discovery that a population or species is in danger may not leave time to discover proper requirements for its protection (including captive propagation). The Rossis also tread on the controversial topic of relaxing regulations regarding captive maintenance and breeding—a topic that tends to arouse heated debate. They return to this discussion in several individual accounts regarding protected species.

Although the contents list four separate parts, this book is really organized into two distinct sections. Part I (Keeping Snakes: General Care) deals with various aspects of snake biology and husbandry, while Parts II, III, and IV are all species accounts. Part II deals with the majority of Western species, Part III with venomous species, and Part IV with assorted subspecies that are more thoroughly treated in Volume I.

In general, the editing of Part I could have been much better. There are enough grammatical errors and misspellings to be annoying. Anthropomorphic language is frequently used (i.e., a snake being "bored with the same food item") and odd terminology is common (i.e., "pop the snake," referring to everting the hemipenes). The writing itself is also occasionally awkward and the organization sometimes seems haphazard as topics are often repeated in different sections. A few specific examples include a "Summary" section that has the same heading level as the section it is summarizing and tables that list snakes in alphabetical order by common name only. Although the individual accounts do include scientific names, it would be helpful to include these in the

tables as well. Many laypersons may prefer this alphabetical approach, but it should be consistent throughout the book. The citation format is also inconsistent. Likewise, the tone of the book often changes abruptly. At points there is the assumption of a large technical and medical knowledge on the part of the reader, while in other places the writing is extremely elementary, leading to a difficulty in assessing the target audience for this book. This is especially true with the medical portions of the book where the first author, himself a DVM, too often writes as if reptile-familiar veterinarians are available everywhere (which is sadly still far from true). At times it is unclear which treatments require the aid of a veterinarian and those which may be accomplished by the educated layperson.

Most of the information contained in this book appears to be well-researched and sound, but there are a few subjects which do not seem quite up to par. Despite their laudable approach of tailoring husbandry to particular species' needs, the authors make several comments to the contrary. A place this repeatedly comes up involves diet. The authors suggest training captive snakes of most species to feed upon domestic mice, if necessary by scenting them with natural prey items. This seems to be counter to their aim of species-specific husbandry and catering more to the amateur snake-keeper with limited funds and limited access to natural prey items. Another example involves group housing of snakes. It is stated that snakes should not be housed together outside of breeding seasons, at one point making the statement that "juveniles of all species do better alone" (p. 60). I can however think of several studies suggesting the opposite among natricine snakes alone, and in personal experience I have found no better way to stimulate poor feeders than to place them in a group of similar-sized conspecifics.

Another element I have some disagreement with concerns hibernation/brumation/winter cool-down. Cool-down using the area's naturally occurring winter climate is recommended, but the authors need to better describe what problems and conditions to avoid in natural "brumatoriums." An unusually cold night can be quite devastating even to a local species if it is not housed in a suitably insulated place. The Rossis also seem to be under the impression that "artificial brumation" does not allow for any activity on the part of the snake, especially regarding drinking, which is simply false. Other questionable claims include the assertion that no snakes should be cooled in groups, and that two months is thought to be the minimum time for cool-down.

A few other particular statements also raise an eyebrow, some of which I will list here in example. The suggested "humane" killing of rodents by placing them in small airtight jars may surprise many animal care committees, and comments regarding hybrid vigor and the detriments of reduced gene flow (in favor of releasing some captive snakes) are bound to displease some ecologists. I found the suggestion to cover neonate water bowls with a lid with a hole in it dangerously reminiscent of a trap that could easily drown entrants. Two topics that needed more description or literature support were the suggestion that tail stripes could be used to sex snakes and something called "Cage Complacency Syndrome."

A topic not touched upon which may be of use would be methods of marking individuals for identification. This was odd given their emphasis on thorough record keeping, an extremely positive and a most helpful suggestion for anyone keeping several snakes.

Many of the problems of Part I, notably, both the writing quality and literature citations, are largely resolved in Parts II–IV. The photographic plates are nice, though it would be helpful if the text entries referred to the appropriate plate and vice versa. Each entry is a fairly complete description of the species in question, though it would not replace a good field guide. It is clear that the authors attempt to keep up with the current usage of names, but it would also be helpful if they included prior names and key citations on which their naming decisions are based. They do comment on nomenclatural problems in the section on garter snakes, a group in particular systematic flux.

Each entry in Parts II and III (and a few in Part IV) includes a summary box with a range map, species name (common and scientific), a "Maintenance Difficulty Index," average size, food, cage size, substrate, ventral heat, UV light, temperature range, and special considerations. The sections on food through temperature range serve as a quick reference to general housing requirements tailored to the particular species and are elaborated upon in the text. It is often unclear whether snakes benefit from UV light, but the authors cite evidence for or against its use in particular species."Special Consideration" includes any warnings regarding diet, likely parasitism, behavioral tendencies, etc. This is also where venomous or protected species are noted. The Maintenance Difficulty Index operates on a useful 5-point scale, with 1 being easiest and 5 most difficult (there are a very few 5+ animals described, such as the spotted leafnose snake, *Phyllorhynchus decurtatus*), but the scale probably does not need to be described in every entry.

There are consistent reports on known sensitivities to antibiotics or anti-parasite drugs, as well as species tendencies toward various health problems. A useful recipe for "Swamp Tea" (an acidic, swamp-like water made with tea) is given in the Graham's crayfish snake (*Regina grahamii*) account. This may have been better placed in the Housing section of Part I with other such maintenance details.

Several species with populations in danger are discussed in detail. Protected snakes are noted (including states in which they are protected), and the authors state that they do not suggest private collection of these animals (although the previously noted opinions regarding legal captive propagation are usually reiterated). In light of the great care taken to describe such predicaments, I was surprised to find the San Francisco garter snake (*Thamnophis sirtalis tetrataenia*) not listed as being protected despite its inclusion on the Federal Endangered Species list.

The bias towards switching every possible species to feeding upon domestic mice again rears its head, to the point where Food entries in the summary boxes almost invariably include "mice," thereby no longer reflecting the animals' natural diet.

Part III deals with venomous species, and opens with some guidelines to safety procedures and additional housing suggestions, as well as a disclaimer that the authors believe that no venomous snake should be handled except in the case of medical emergency. They also are careful to warn of venom toxicity and known fatalities in the individual accounts, and repeat their warning against handling venomous snakes despite seemingly calm dispositions. Part IV includes very brief summaries of species treated more completely in Volume I.

Despite its many small faults, I still recommend this book because of the paucity of herpetoculture references for native American species. Unfortunately, the high price will make it less attractive to those interested amateurs who would benefit most from it. I am always on the lookout for such practical and useful books to recommend to "budding herpetologists," and I even learned a few new tricks from this one. I was personally pleased by the entire section devoted to garter snakes, including a reference to a longevity record for coast garter snakes (*Thamnophis elegans*

terrestris) which was set by a snake of mine. I plan on keeping my copy of this book handy to help deal with the frequent calls I receive from students, mothers, and neighbors asking not only for identification but also for information on "how to keep it."

A Field Guide to Reptiles and the Law, by John P. Levell. 1995. Serpent's Tale Books, Excelsior, Minnesota. 240 pp. Softcover. US $29.95. ISBN 1-885209-03-7. Available from Zoo Books, 464 Second St., Excelsior, Minnesota 55331, USA.

JOHN MORIARTY
Hennepin Parks, 3800 County Road 24
Maple Plain, Minnesota 55359, USA

A Field Guide to Reptiles and the Law is an up-to-date guide to the state and U.S. laws effecting reptiles and amphibians. Levell's book covers CITES, the U.S. Endangered Species Act, and miscellaneous federal regulations, but the majority of the book deals with state regulations. Listings of state endangered and threatened species are accurate and current. The book also covers state regulations on commercial and non commercial harvest, importation of native and exotic species, and some unique regulations. One of the main things the state section reveals is the lack of regulations in many states.

One example is my state, Minnesota. It is illegal to possess or collect endangered and threatened species without a special permit. This protects five-lined skinks, Blanding's turtles, and wood turtles. There are commercial regulations and licenses for snapping turtles and frogs (there is no definition of "frogs" in state regulations, so by default it includes all anurans). The commercial and non-commercial taking of snapping turtles requires a 10-inch minimum carapace width. Frogs can not be sold as bait between March 31 and May 16 (the closed season for bass) and only northern leopard frogs and bullfrogs can be taken for purposes other than bait (biological supply trade). The taking of other species of frogs for the pet trade or other uses appears to be unregulated. There are 30 species, including all of the snakes, that have no protection and an additional 17 species with only partial protection. The Minnesota Department of Natural Resources doesn't even have the authority to regulate most amphibian and reptile species.

Minnesota's regulations are similar to many states where there is a good endangered species law (except for North Dakota, Utah, West Virginia, and Wyoming), poorly written commercial turtle rules, a wide open bait frog law, and little or no protection for the rest of the species. There are a number of states that ban the commercial trade of native amphibians and reptiles, but do not allow for the trade of captive bred specimens. There should be a permitting system that would allow trade in captive bred amphibians and reptiles, as is commonly found with many bird and mammal species.

The most complete reptile and amphibian regulations are found in Maryland. Maryland has a good threatened and endangered species law, well written native species laws including taking, importation, commercial trade, and captive maintenance regulations. If you live in Maryland send your Department of Natural Resources (DNR) a thank you note. If you live in another state you might consider sending your DNR a copy of this book.

There are a number of "interesting" laws found in the book. One of these is Kansas's taking law under which one can take unprotected amphibian and reptile species (68 of 97 species) by firearms (except machine guns), bows, crossbows, traps, deadfalls, snares, nets, dogs, and poison. I always thought Kansas had a wealth of herpetologists because of the reputation of KU, but I guess it is because of the thrill of going on a toad hunt with the ol' 12 gauge. Many other states have equally absurd taking laws, while other states don't appear to prohibit any method of taking.

In Massachusetts there is an extensive listing of non-native species that can be imported. Part of the list includes pythons and boas (Boidae) stating that a permit is needed except for common boa (under nine feet), green tree python, Colombian rainbow boa, sand boas, ball python, reticulated python (under eight feet), and African rock python (under eight feet). The next line says all other members of the family Boidae are exempt except (permit required) emerald tree boa. Simply put, the only boids needing permits are emerald tree boas, reticulated and African rock pythons over eight feet, and common boas over nine feet. What did emerald tree boas ever do to Massachusetts? What makes a big Burmese python and anaconda exempt? Discrepancies in various exemptions can be found in many state regulations. I wonder why a state agency would even try to regulate a non-native species that is not dangerous to humans or the environment.

Levell has done a good job dealing with the various agencies and an excellent job biting his tongue for not making any commentary about many of the laws. I was disappointed that there was not a summary that picked out the best pieces of the different laws for a proposed model state amphibian and reptile statute.

This book highlights the fact that most states do not have the laws necessary to protect native amphibians and reptiles. Conservation-minded herpetologists should use this book to start the process of revising their state's regulations, because without some controls on the taking and trade of amphibians and reptiles, long-term conservation will be difficult. Protecting habitat without protecting the animals that live there will not help conservation.

Amphibians and Reptiles Native to Minnesota, by Barney Oldfield and John J. Moriarty. 1994. University of Minnesota Press, 2037 University Avenue Southeast, Minneapolis, Minnesota, 55455-3092, USA. 237 pp., US $25.95. Hardcover. ISBN 0-8166-2384-8.

ERIK RUSSELL WILD

The University of Kansas, Lawrence, Kansas 66045-2454, USA
rosco@falcon.cc.ukans.edu

Increasing concern over worldwide declines in amphibian populations and the growing interest of non-specialists in herpetology has created a need for updated accounts of state and regional herpetofaunas. The 50th anniversary of the publication of Breckenridge's *Reptiles and Amphibians of Minnesota* (1944) is appropriate timing for the publication of Oldfield and Moriarty's contemporary treatment, *Amphibians and Reptiles Native to Minnesota*.

Amphibians and Reptiles Native to Minnesota is organized in a manner similar to most state or regional guides. There are 11 non-numbered chapters, the first eight of which make up one-fourth of the book. These chapters introduce the state of Minnesota ("History of Herpetology in Minnesota;" "Habitats"), the field of herpetology ("Observing, Studying, and Photographing Amphibians and Reptiles;" "Conservation;" "Common Amphibian and Reptile Problems"), and identification ("Amphibian and Reptile Identification") with a checklist and keys to the native species. The majority (three-fourths) of the book is comprised of three chap-

ters of species accounts ("Amphibians;" "Reptiles;" "Species of Possible Occurrence") of the 48 species that occur in the state, plus six species that could possibly occur there.

The first chapter provides a thorough synopsis of the history of herpetology in Minnesota. This chapter is followed by a description of the major aquatic and terrestrial habitats where amphibians and reptiles can be found in the state, including color photographs of the habitats and a handy table listing the species that occur in each. One unfortunate oversight here is the absence of a discussion (or map as provided by Breckenridge, 1944) of the major physiographic provinces of the state. Little is mentioned regarding the western prairie and eastern forest ecotone that bisects the state and which may explain the limits of some species distributions. Next, the authors include a chapter on methods, techniques, and strategies of observing and studying amphibians and reptiles. This section, written at an introductory level, adds little information not found in other such guides except for idiosyncrasies of herping in Minnesota and a unique and informative section on photography that will benefit even specialists. The quality of the 115 color photographs throughout the book are testament to Oldfield's photographic expertise. An important theme introduced in the next chapter, and continued throughout the book, is an emphasis on conservation of reptile and amphibian populations. In this vein, the authors give the official status of each species as threatened, endangered, or of special concern; unfortunately, they do not define what these labels mean in Minnesota. Nevertheless, the authors' efforts to instill a conscience toward amphibians and reptiles in the general public should be applauded. They devote an entire chapter to "Common Amphibian and Reptile Problems" (an unfortunate title because the chapter does not deal with problems that amphibians and reptiles face, but problems that people have with them) that anticipates the most popular questions of the general public. This chapter should prove useful not only to the layperson directly, but also to the non-specialist biologist who has to address these concerns and educate the public.

Chapters 6–8 set up the remainder of the book which comprises the species accounts. Chapter six, "Amphibian and Reptile Identification," explains how to use the book and the format and approach to the species accounts. This chapter is followed by a comprehensive list of species including current specific, subspecific, and common names. The next chapter introduces the authors' innovative circular keys. One starts at the center and moves sequentially toward the periphery according to dichotomous choices of features (although there is one trichotomous choice in the turtle key) until identification is achieved. The keys are essentially the traditional written dichotomous keys but in diagrammatic representation and so are much easier to use, especially when tracing backwards to examine alternative choices. I anticipate that these keys will be popular with non-specialists and young, budding herpetologists. The accompanying line drawings (Figures 1–6) are clear but hidden on the backside of the last key and so are of limited usefulness. A much better location would have been in the spaces surrounding the keys themselves or in the species accounts near the appropriate discussion in the text. It seems that for the level that the book was written there should be many more simple, labeled line drawings showing the parts of a generalized frog, salamander, turtle, etc., and explicitly showing comparisons of diagnostic features discussed in the text; there are some things that not even the best photographs can achieve.

The chapters "Amphibians" and "Reptiles" introduce their respective classes with good, general treatments of morphology, physiology, reproduction, and ecology written with a sophistication just above the rest of the book. This is followed by a useful description of each of the families represented in Minnesota. Each species account includes five subsections: Description, Distribution, Habitat, Life History, and Remarks. The descriptions are sufficient, clear, and emphasize diagnostic characters. The authors make appropriate comparisons that are consistent with the circular keys. The general distribution of each species in North America is described along with a more detailed explanation of the range and habitat in Minnesota. In the upper left corner of a left page of each account is a map of Minnesota with the counties delineated. The amphibian maps are green whereas the reptile maps are brown; this, along with the consistent placement on the page, make them easy to find when thumbing through the book. The presence of a species in a particular county is indicated by a dot. To the authors' credit, they distinguish between sightings/literature records and vouchered records. Furthermore, the vouchered records are identified as pre- or post-1960 (the significance of 1960 was not mentioned). This will provide a sense of the validity of a species' occurrence in a county or acknowledge the need for better documentation. With the growing concern for decline in amphibian populations, these maps will be very useful in recognizing a reduction in a species' range over the past 34 years (e.g., see map for the Great Plains toad). However, the authors fail to emphasize this virtue in the text. The authors efficiently incorporate new, relevant information and emphasize, when available, data particular to Minnesota. For example they include the unusual event "... reported in Minnesota in which a Snapping Turtle killed an adult Trumpeter Swan." Likewise, they emphasize the ability of species to deal with difficult environmental conditions (long cold winters) in the northern extreme of their range such as freeze tolerance in the gray treefrog, Cope's gray treefrog, and the wood frog, and they report unusual winter activity like a painted turtle seen under the ice or a milk snake active in late November. Each species account has at least one, but usually several, color photographs of excellent quality that clearly depict important features and geographic and ontogenetic variation consistent with the discussion in the text.

I found few technical errors in the book: on page 96 the authors discuss the two variants of the northern leopard frog and state that they differ by a "single gene" which, in modern terms, probably means allele; and the Aleksiuk citation in the common garter snake account is spelled differently than that in the Literature Cited. The amphibian accounts by Moriarty tend to be shorter than those for the reptiles by Oldfield, and at times it seemed that Moriarty stopped short of a complete explanation or that something had been left out. The tadpole descriptions are so brief as to be of little use, and it is a shame that Oldfield did not apply his photographic skills to amphibian larvae. These criticisms notwithstanding, the species accounts are well illustrated, organized, and written. Thus, the authors' principal objective of providing contemporary accounts and enabling identification of Minnesota's amphibians and reptiles has been achieved.

The last chapter, "Species of Possible Occurrence," discusses six species in neighboring states for which there is reason to expect them in Minnesota. These brief one-page accounts include a short description of the species and its habitat, a discussion of the potential range, and a large color photograph of the organism. The book ends with a 75-word glossary, which seems sufficient to cover most of the technical terms of the book, a list of resources, including reference books and herpetological organizations, and 277 literature citations.

In general, Oldfield and Moriarty provide an interesting and readable introduction to the amphibians and reptiles of the Land

of 10,000 Lakes. The text was not written for the professional herpetologist, but anyone interested in amphibians and reptiles in Minnesota should refer to this book. The authors' novel contributions of a synopsis of Minnesota literature, innovative circular keys, new geographical records, fresh personal observations, and excellent photographs make it unique among other regional guides. Add to this clear writing and a low price and you have an exceptional source for the growing populace of Minnesotans interested in herpetology. This book should play an important role in encouraging awareness and appreciation of amphibians and reptiles in this conservation-minded state.

LITERATURE CITED

BRECKENRIDGE, W. J. 1944. Reptiles and Amphibians of Minnesota. University of Minnesota Press, Minneapolis. 398 pp.

Amphibian and Reptile Species of Special Concern in California, by Mark R. Jennings and Marc P. Hayes. 1994. Published by the Inland Fisheries Division, California Department of Fish and Game, Rancho Cordova, California. iii + 255 pp., 6 tables, 49 figures, and 5 appendices. Softcover. US $20.00 (plus $2.50 s/h and $1.55 sales tax for California residents). Available from California Department of Fish and Game, Natural Heritage Division, 1416 Ninth Street, Sacramento, California 95814, USA. Tel. (916) 327-5957.

HARTWELL H. WELSH, JR.
USDA Forest Service, Pacific Southwest Research Station
1700 Bayview Drive, Arcata, California 95521, USA

This is an impressive effort that was seven years in the making. Under a contract from the California Department of Fish and Game that began in 1988, the authors assembled pertinent data on the status of 81 potentially threatened species or subspecies of the total 130+ taxa of reptiles and amphibians occurring in California. Their effort is the fourth in a series of reports commissioned by the department (it was preceded by reports on the birds, mammals, and fish), examining species of special concern in California. The California Department of Fish and Game deserves credit for its proactive stance in initiating this series (despite an adverse political climate). This is a commendable effort to promote the conservation of the rich biotic heritage of the state. Few state game departments in the U.S. have made such a conscientious effort to investigate and inform the public about the status of their native non-game species, let alone their herpetofauna. The only comparable work of which I am aware is *The Action Plan for Australian Reptiles* (Cogger et al. 1993), a comprehensive national effort commissioned by the Australian Nature Conservation Agency.

The quality of the final product demonstrates that the authors were a good choice for the task. This document is impressive in scope and thoroughness, and it sets a high standard for other responsible natural resource agencies to follow in this era of declining biotas. In addition to using all the usual sources of readily available information (scientific literature, localities and archival records from pertinent state and national museums, unpublished field notes, field surveys, and site visits) the authors mailed extensive questionnaires to 127 individuals with particular knowledge of individual species, and conducted interviews or exchanged letters with another 90 individuals to inquire on specifics about selected taxa.

The information is well organized into 48 individual accounts with brief descriptions of each taxon (species or subspecies), taxonomic remarks, distributions (with maps), life history and habitat information, status reviews, and management recommendations. Although pertinent current literature is extensively cited, the authors have not attempted to be thorough. Life history and habitat information is intentionally limited to that which is necessary to understand the threats to a given taxon. Nonetheless, this often amounts to an extensive review of what is known about the life history of a particular species. While the report summarizes the current status (as of 1993) of a majority of native species, it does not include those species already listed as threatened or endangered under either the state or federal Endangered Species Act (e.g., *Gopherus agassizii, Gambelia sila, Ambystoma macrodactylum croceum*). The focus is on prevention of decline, through examination of the status and the nature of current or potential threats to those taxa that may now be, or could potentially become, candidates for listing.

The distribution maps are worthy of some discussion. They depict major river drainages and county boundaries with coded symbols for all known localities. The authors have coded each locality as extant based on verified sighting or museum record, or extinct based on verified sighting or museum record. While it may seem somewhat risky to assume extirpation at a previously known site (especially for a small cryptic species like *Phrynosoma m'calli* or a secretive snake like *Lampropeltis zonata parvirubra*), the authors have used the conservative criteria of multiple visits over a ten year period, or evidence of habitat alterations clearly detrimental to a given species (e.g., draining of aquatic habitats or the replacement of native vegetation with a subdivision) to establish absence. These are sound and reasonable criteria for demonstrating absence and an essential methodological element for monitoring population status over time.

The authors concluded that 33 of the 81 potentially "at risk" taxa they examined did not warrant listing at this time. However, the remaining 48 taxa reviewed warranted listing at some level, with species requiring aquatic habitats at greatest risk. Such a conclusion is hardly a surprise for a state whose citizens have fought over water since the original human inhabitants were relegated to marginal habitats or extirpated. This report should be very useful in helping state resource agencies focus their limited resources for conservation where they can do the most good.

The text and maps are complimented in many accounts by black and white line drawings of the subject taxon from the works of Robert C. Stebbins, the premier illustrator of California's herpetofauna. The extensive, and relatively up-to-date, bibliography is the most comprehensive ever compiled and readily available in one place for California's herpetofauna and it alone constitutes a great resource for those interested in this fauna.

The two localities for *Plethodon elongatus* in Mendocino County designated with question marks are in fact errors. These sites were confused with two localities from further north as a result of a data transfer glitch between the source and the state's natural diversity data base. This and other minor mistakes could have been prevented had species experts been asked to review the final accounts. Overall though, and particularly given the amount of detail, errors are few. This report is a welcome addition to the literature on the conservation biology of North American reptiles and amphibians.

LITERATURE CITED

COGGER, H., E. CAMERON, R. SADLIER, AND P. EGGLER. 1993. The Action Plan for Australian Reptiles. Australian Nature Conservation Agency, GPO Box 636, Canberra, ACT 2601.

PUBLICATIONS RECEIVED

Conservation Genetics: Case Histories from Nature, edited by John C. Avise and James L. Hamrick. 1996. Chapman & Hall, New York. Hardcover, 512 pp. US $69.95. ISBN 0-412-05581-3. Available from International Thomson Publishing, 7625 Empire Drive, Florence, Kentucky 41042, USA. Fax (606) 525-7778; e-mail: order@chaphall.com.

Avise and Hamrick have produced a highly readable treatise on the application of molecular genetic information to conservation biology. Nineteen principal authors contributed to this volume, covering an array of subjects from endangered cetaceans to plants. The lone herp-oriented chapter, "Conservation Genetics of Marine Turtles," (authored by Brian Bowen and Avise) will be of greatest interest to herpetologists, although marine turtle researchers will likely find this familiar territory. Perhaps more valuable will be the discussions in other chapters of issues such as reduced gene flow, genetic subdivisions within species, and the implications for conservation strategies—both biological and political. Other chapters offer a regional or ecosystem perspective by comparing genetic features among diverse taxa that occur in the same area.

Amphibian Populations in the Commonwealth of Independent States: Current Status and Declines, edited by Sergius L. Kuzmin, C. Kenneth Dodd, Jr., and Mikhail M. Pikulik. 1995. Pensoft Publishers, Moscow and Sofia. Softcover, 159 pp. US $25 + $4 s/h. ISBN 954-642-007-7. In English, with abstracts in English and Russian. Available from Dr. Lyubomir D. Penev, PENSOFT Publishers, 1 Chekhov Street 208 #6, 1113 Sofia, Bulgaria. Fax: 359-2-736188; e-mail: pensoft@infolink.infotel.bg.

This is a collection of 22, mostly short, papers concerning amphibian populations in the former Soviet Union, produced in response to the worldwide amphibian decline. Original data are presented on the distribution, life histories, morphology, and biochemistry for several species. Seven families are represented: Salamandridae (*Salamandrella, Triturus*); Ranidae (*Rana*); Pelobatidae (*Pelobates*); Bufonidae (*Bufo*); Discoglossidae (*Bombina*); Hylidae (*Hyla*); and Pelodytidae (*Pelodytes*).

Self-Assessment Color Review of Reptiles and Amphibians, by Fredric L. Frye and David L. Williams. 1995. Iowa State University Press, Ames. Softcover, 192 pp. US $34.95. ISBN 0-8138-2990-9. Available from Iowa State University Press, 2121 South State Avenue, Ames, Iowa 50014-8300, USA. Tel. (800) 862-6657; Fax (515) 292-3348.

This is a collection of photographs—most in color—accompanied by informational text that present >250 case studies. The book is targeted primarily as a source of continuing education for veterinarians, though advertised as also useful for herpetologists and pet owners. Illustrations depict specific unidentified conditions, which the reader is asked to identify or recommend a course of treatment. The cases depicted range from common conditions that most herpetoculturists would recognize to the more unusual or rares ones that few veterinarians will have seen.

Care and Breeding of Panther, Jackson's, Veiled and Parson's Chameleons, edited by Philippe de Vosjoli and Gary Ferguson. 1995. Advanced Vivarium Systems, Inc., Santee, California. Softcover, 128 pp. US $12.00.

This is another addition to the highly popular series of small books targeting the burgeoning population of herpetoculturists. In this volume, various experts on the husbandry of *Chameleo* (sensu lato) offer tips for successful maintenance and reproduction of these fascinating lizards. Natural history summaries are provided by way of introduction for each of the four species covered—*C. pardalis, jacksonii, calyptratus,* and *parsonii.*

Turtle Islands: Balinese Ritual and the Green Turtle, by Charles Lindsay. 1995. Takarajima Books, New York. Hardcover, 124 pp., 90 color photographs. US $39.95. ISBN 1-883489-10-5. Available from Takarajima Books, 200 Varick Street Suite 507, New York, New York 10014, USA. Tel. (212) 675-1944; Fax (212) 255-5731.

Author-photographer Charles Lindsay chronicles the relationship between the people of Bali and the green sea turtle (*Chelonia mydas*). This turtle occupies a prominent place in religion and mythology—indeed, Balinese (Hindu) religious practice requires the sacrifice of turtles. Increasingly, commercial exploitation is taking a toll on turtle populations. Lindsay captures all of this in colorful, if distressing, detail.

Turtles, by Anita Baskin-Salzberg and Allen Salzberg. 1996. Franklin Watts, New York. Hardcover. 63 pp. US $20.95. ISBN 0-531-20220-8. Available from Franklin Watts, Sherman Turnpike, Danbury, Connecticut 06813, USA. Tel. (800) 621-1115.

A book for budding turtle enthusiasts, written by people who actually know something about turtles. Basic turtle facts—distribution, size, longevity, physical characteristics, and even a brief fossil history—are presented. Excellent color photographs offer a view to the diversity of turtles. Conservation problems facing turtles are discussed, and young readers are encouraged to become active in helping solve these problems.

ERRATUM

In the range extension for *Desmognathus aeneus* published in the December 1995 issue (Livingston et al., Herpetol. Rev. 26:207), the name of the first collector was misspelled. The first South Carolina specimen of this species was collected by a group that included D. A. Jackan (not D. Jackson as previously listed).

Graptemys kohnii (Mississippi Map Turtle). Illustration by Dan C. Holland.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Techniques, Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at 303 West 39th Street, Hays, Kansas 67601-1518, USA. Application to mail at 2nd Class Postage rates is pending at Hays, Kansas with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, P.O. Box 626, Hays, Kansas 67601-0626.

All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

Please notify Karen Toepfer, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 600		$300
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 600	$150

For back orders only: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA (fax 314-977-3658). E-mail: aldridge@sluvca.slu.edu.

Society for the Study of Amphibians and Reptiles

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

Annual Dues and Subscriptions: Annual membership dues for the year 1996 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. All members receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with Visa or MasterCard (account number and expiration date must be provided). Payment should be sent to: Karen L. Toepfer, SSAR Treasurer, P.O. Box 626, Hays, Kansas 67601–0626, USA. Telephone: (913) 623-4258; Fax: (913) 625-8890; e-mail: fmkt@fhsuvm.fhsu.edu.

Future Annual Meetings

1996 — University of Kansas, Lawrence, Kansas, USA, 24–29 July (Linda Trueb, Chair).
1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July (Theodore Pietsch, Chair).
1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).

SSAR BUSINESS

HR Staff Changes

Due to a continuing increase in submissions to Natural History Notes, a new section editor position has been added to help spread the work load. Paul Stone has joined our staff, and will handle all Natural History Note submissions concerning snakes and turtles. Charles Painter will continue to handle all manuscripts concerning amphibians, and Lee Fitzgerald will cover lizards, amphisbaenians, crocodilians, and Sphenodontia. Contributors should send Natural History Note manuscripts to the appropriate section editor. Stone's address is: *Paul A. Stone, Department of Biology, University of Central Oklahoma, 100 North University Drive, Edmond, Oklahoma 73034, USA; e-mail: pstone@aix1.ucok.edu.*

Other staff changes include the addition of Hidetoshi Ota and Gustavo Scrocchi as new section editors for Geographic Distribution. Ota will handle all submissions concerning records for the Old World (Eurasia, Africa, Oceania, Indian Ocean Islands), while Scrocchi will cover South American records. Joseph Collins will continue to process records for Canada and the U.S., and Jerry Johnson will handle reports for México and Central America. Ota's address: *Hidetoshi Ota, Tropical Biosphere Research Center, University of the Ryukyus, 1 Senbaru, Nishihara-cho, Okinawa 903-01, Japan; e-mail: ota@sci.u-ryukyu.ac.jp.* Scrocchi's address: *Gustavo J. Scrocchi, Instituto de Herpetologia, Fundacion Miguel Lillo, Miguel Lillo 251, 4000 Tucuman, Argentina; e-mail herpetol@untmre.edu.ar.*

HR's long-time section editor for Recent Population Changes, Ralph Axtell, is stepping down to pursue other things (lizards, mainly). We thank Ralph for his many years of dedicated service to his colleagues and wish him well. Authors of Recent Population Changes manuscripts should send these directly to the Editor.

Publications Needed for SSAR Graduate Student Reprint & Book Scavenge

Reprints and other publications are needed for the 1996 SSAR student reprint scavenge. The graduate student social is greatly enhanced by the opportunity for students to acquire various herpetological literature. Now would be a good time to disseminate those extra reprints you have cluttering your office. Anyone wishing to donate items in advance may send them to: *Jeff Parmelee, Graduate Student Social Committee, Natural History Museum, University of Kansas, Lawrence, Kansas 66045-2454, USA.*

Items Needed for SSAR Auction

Joe Collins will be conducting the SSAR auction during the annual meeting at the University of Kansas in July 1996. All proceeds from the auction go to the SSAR treasury, and help to continue the production of diverse publications and services which has made the SSAR the largest professional herpetological society in the world. Items of value as well as those that lend themselves to humor are always welcome. Joe is skilled at removing large quantities of cash from auction participants through the judicious use of beer and plastic. Anyone wishing to donate auction items in advance should send them directly to: *Joseph T. Collins, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA.*

About Our Cover

Interest in the herpetological fauna of the Indian Ocean island of Madagascar has surged in recent years. High levels of endemism, prominent radiations in several groups (especially frogs, geckos, and chameleons), and relict taxa have drawn the attention of many researchers. The publication of the first edition of a field guide to Madagascan herps (Glaw and Vences, 1992) stirred further interest. In this issue of *Herpetological Review*, Ron Nussbaum and Chris Raxworthy, who together have made a number of important contributions to our knowledge of the Madagascar herpetofauna, offer a detailed review of the second edition of the Glaw and Vences field guide.

Frogs of the genus *Boophis* are endemic to Madagascar and, together with the monotypic *Aglyptodactylus*, represent the subfamily Rhacophorinae on this island. Most *Boophis* are tree dwellers, and all have enlarged tips on fingers and toes. Thirty-six species are currently recognized, but this is definitely not the sum total. Since 1990, thirteen new species and two subspecies have been described, and others await description. The very first Malagasy frog described and named in the literature was *Boophis goudoti*, a large species which is sometimes eaten by the local people. This frog was described by Johann Jakob von Tschudi in 1838, and by 1870, only eight additional species had been added to the list. Herpetologists today are describing new species at a rate higher than ever before. In 1990, about 150 species of frogs were known from Madagascar, but evidence suggests that this figure could possibly double by the year 2000.

Herp photographers will be hard-pressed to find a more photogenic group of animals than the Malagasy *Boophis* species. The specimen on the cover is an adult female *Boophis erythrodactylus* (Guibé 1953), collected by Frank Glaw at Mandraka during the 1994-95 summer season. The red toe and finger disks are diagnostic for this species. Males call from vegetation next to fast flowing brooks and the tadpoles live in rapids. Specimens of *B. erythrodactylus* and *B. mandraka* can secrete a strong-smelling fluid when touched, the function of which presumably is to enable frogs to identify conspecifics (Blommers-Schlösser 1979. Bijd. Dierkunde 49(2):261-312) and perhaps serves a defensive function as well.

One advantage of photographing amphibians and reptiles, as opposed to mammals and birds for example, is that the photographer can very often manipulate the subject. As such, the specimen on the cover was positioned on a plant set up in the foyer of a hotel in Antananarivo. Frank Glaw provided flashlight illumination by which to focus, and **Marius Burger** shot away on Fujichrome 100 ASA film using a 35mm SLR Minolta X700 camera, a 100mm Minolta lens (1:2 macro function) and a small flash unit.

Marius is a research assistant in the Scientific Support Services section of Eastern Cape Nature Conservation in South Africa. Herpetology constitutes a relatively minor part of his duties, but he does chase after these animals whenever the opportunity arises. He says that visiting places like Madagascar can be both exciting and quite frustrating if you are a herp fanatic—particularly when you are not permitted to collect specimens, be it for the museum pickle pots or to take home as pets. Fortunately, there exists the option of capturing specimens on film. Burger's photos have been featured in a number of publications, mostly in books on Southern Africa herpetology. Quite a few of his pictures appear in the Glaw and Vences field guide reviewed in this issue.

Society for the Study of Amphibians and Reptiles 1996 Annual Meeting

Dates: 24–29 July 1996
Place: The University of Kansas, Lawrence, Kansas, USA

Keynote Address: "New Drugs from Old Frog Skins," by Michael J. Tyler (University of Adelaide).

Symposium: "A Tropical Natural History: Essays in Honor of William E. Duellman." *Organizer:* John D. Lynch (The University of Nebraska).

Symposium: "Diversity of Approaches to Amphibian and Reptilian Systematics." Participants restricted to graduate and post-doctoral students. *Organizers:* Daniel J. Meinhardt and Joseph R. Mendelson III. *Contact:* Joseph R. Mendelson III, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA; Tel. (913) 864-3439; Fax (913) 864-5335; E-mail: sapo@falcon.cc.ukans.edu.

Symposium: "Population Status and Conservation of Amphibians." Sponsored by the US DAPTF. *Contact:* Michael J. Lannoo, Muncie Center for Medical Education, Indiana University School of Medicine, MB209, Ball State University, Muncie, Indiana 47306, USA; Telephone: (317) 285-1050; Fax: (317) 285-1059; E-mail: 00mjlannoo@bsuvc.bsu.edu.

Workshop: "Herpetological Collections: Funding, Growth, and Management." *Contact:* John E. Simmons, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA; Tel. (913) 864-3342; Fax (913) 864-5335; E-mail: jsimmons@kuhub.cc.ukans.edu.

Conservation Forum: "Relocation and Reintroduction of Amphibians and Reptiles: Viable Options or Half-way Technology?" *Organizer*: C. Kenneth Dodd, Jr. (National Biological Service).

Oral and Poster Sessions: Several concurrent sessions each day.

Student Paper Awards: Seibert Prizes to be awarded to the two best student-presented papers at the meeting ($250 first prize, $150 second prize).

President's Travelogue Slide Shows: Profusely illustrated lectures of exotic amphibians and reptiles and their habitats. "Ice Cool Herps: New Zealand's Herpetofauna," by Louis J. Guillette (University of Florida); "From the Pacific to the Amazon, a Natural look at Northwest South America," by William Lamar (The University of Texas at Tyler); "Herps of South Asia," by Indraneil Das (Madras Crocodile Bank Trust).

Multimedia Presentations: "Herps of the West" and "Amphibians of the Appalachians" by David Dennis and Eric Juterbock; "Herpetological Namesakes" by Kraig Adler and David Dennis.

Declining Amphibians: Annual board meeting of the IUCN/SSC Declining Amphibian Populations Task Force.

Social Activities: Welcoming Social (honoring Roger Conant, Henry S. Fitch, Hobart M. Smith, Robert C. Stebbins, and Ernest E. Williams), Auction, Barbecue Picnic, Graduate Student Social (including herpetological trivia quiz with prizes).

Art and Photographic Exhibit: Featuring herpetological art and photographs.

Rare Book Exhibit: A special exhibit, "The Slimy Toeth," by Sally Haines in the Spencer Research Library, featuring 16th and 17th century books dealing with herpetology.

Live Exhibit: Amphibians and reptiles from Kansas, presented by the Kansas Herpetological Society.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Costs: Preregistration $125 regular, $90 student; late registration fee after 1 June $170 regular, $125 student; companion (social only) preregistration $30, after 1 June $50. Lodging in dormitory: $100 person/5-day package (double occupancy; includes breakfast each day and 3 dinners) and $140 person/5-day package (single occupancy; includes breakfast each day and 3 dinners). Buffet lunch provided at meeting site—$30 for 5 days.

Further Details: Meeting Announcement/Call for Papers was mailed to all North American members of the SSAR in March 1996, and is available upon request from Cathy M. Dwigans, Academic and Professional Programs, Continuing Education, The University of Kansas, Lawrence, Kansas 66045, USA; Tel. (913) 864-3284; Fax (913) 864-5074. Chairperson of Local Committee: Linda Trueb, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA; Tel. (913) 864-3342; Fax (913) 864-5335. E-mail: Trueb@kuhub.cc.ukans.edu.

NEWSNOTES

Lacerta Now on the Internet

The Nederlandse Vereniging voor Herpetologie en Terrariumkunde, publisher of the journal *Lacerta*, has become the first European herpetological society to establish a presence on the Internet. The society may be found at: http://www.xs4all.nl/~lacerta and may be contacted via e-mail at lacerta@xs4all.nl. Manuscripts should continue to be sent by mail rather than electronically.

The society's web page provides a cumulative index to volumes 36–50 (1972–1992) of the journal *Lacerta*, an index to volumes 51–53, summaries (in English) of all papers published in recent issues, and a newsgroup with information on local activities and links to other sites.

North American Amphibian Monitoring Program (AMP) Documents Now Available

The question of the extent, existence, and impact of declines in amphibian populations is a contentious one. In the face of few statistically designed regional surveys, the controversy can only continue, undermining local and national efforts to implement amphibian conservation programs.

The AMP group was formed in response to this need. The group aims to develop solid, statistically defensible regional surveys of amphibians throughout North America. The process of developing those recommendations has not been a simple one. Monitoring methodology for amphibians, while based on countless hours of field time, innovative designs, and published within numerous papers, largely lacks the statistical evaluation and validation investigations necessary to assess their relative merits. In two years time and two international meetings the AMP group has published a preliminary set of documents.

Those documents present a set of recommendations for calling survey implementation. Calling surveys have had sufficient statistical investigations to warrant making a set of recommendations. However, for aquatic surveys, terrestrial salamanders, and atlas projects the group has not set any recommendations for implementation. Rather, we present the merits of techniques applicable for regional surveys and outline what further information will be needed to evaluate them.

We invite researchers and conservationists to participate in the ongoing evaluations of these techniques. The best way to get involved is to become part of the electronic network of AMP. You can do so by sending a message to:

listproc@rana.im.nbs.gov
in the BODY (not the subject line) put the following:
subscribe amp <your name>

Those interested in starting calling amphibian surveys in their state can contact Sam Droege at the address below. All AMP documents are available via the World Wide Web at: http://www.im.nbs.gov; by anonymous ftp site: ftp.im.nbs.gov (in directory /pub/naamp); or by mail from: *Sam Droege, National Biological Service, 12100 Beech Forest Road, Laurel, Maryland 20708-4038, USA; e-mail: frog@nbs.gov; tel. (301) 497-5840; fax (301) 497-5784.*

Holbrook Receives Posthumous Honor

John Edwards Holbrook (1794–1871), author of *North American Herpetology*, was inducted into the South Carolina Hall of Science and Technology on March 8, 1996 in ceremonies held at the University of South Carolina in Aiken. Mr. James L. Knight, Curator at the South Carolina State Museum, presented the award, including the Ernest E. Just Medallion for the Biological Sciences. Dr. Nat B. Frazer, Associate Director of the Savannah River Ecology Laboratory, accepted the award on behalf of the herpetological community. The medallion will be placed in the South Carolina Hall of Science and Technology Research and Display Room in the Academic Center of the Midlands Technical College, Airport Campus, South Carolina.

Staff Herpetologist Position

The Seminole Nation needs a herpetologist to work and live on the reservation located in the Everglades, near Clewiston, Florida, USA. This person will be responsible for developing and curating live reptile and amphibian exhibits, providing educational programs and lectures, and training guides in accurate herpetological interpretation. This person may become involved in captive breeding programs and assist with monitoring and managing reptiles and amphibians on the reservation.

Experience in captive maintenance and breeding, exhibit development, interpretation and working with the public, teaching and field work is required.

Salary begins at $8–10/hour plus a house on the reservation and is based on experience and training. A minimum one-year commitment is preferred.

Please send inquiries or resumes to: *Mr. Jimmie McDaniel, Seminole Tribe of Florida, HC-61, Box 46, Clewiston, Florida 33440, USA. Tel. (800) 949-6101; fax (813) 983-9396.*

Graduate Student Research Assistantship

A graduate research assistantship in stream/amphibian ecology is available for an M.S. candidate starting in Fall 1996. The research will focus on the effects of timber harvest on the distribution and abundance of stream amphibians (tailed frog and Idaho giant salamander) in northern Idaho. For additional information, contact: *Kirk Lohman, Department of Fish and Wildlife Resources, University of Idaho, Moscow, Idaho 83844, USA. E-mail: klohman@uidaho.edu. Tel. (208) 885-7203.*

Project Bog Turtle

Growing concern over the future of the bog turtle (*Clemmys muhlenbergii*) throughout its range has prompted the North Carolina Herpetological Society to establish Project Bog Turtle. Even though bog turtles are protected in every state where they occur, destruction of wetland habitats and collection for the pet trade continues.

Project Bog Turtle emphasizes local involvement in designing management and conservation strategies for the bog turtle and its habitat. The goal is to preserve habitat through direct contact with landowners, and state and federal agencies to prevent the need to place this animal on the U.S. Endangered Species List. Current

activities include bog restoration, population monitoring, and telemetry studies of movement.

Project Bog Turtle is seeking funds for research and restoration projects and development of programs designed to actively involve landowners in conservation efforts. Tax deductible (for U.S. residents) donations may be sent to: *Project Bog Turtle, N.C. Herpetological Society, P.O. Box 29555, Raleigh, North Carolina 27626-0555, USA.*

Carnegie Museum of Natural History Collection Study Grants in Herpetology

The Carnegie Museum of Natural History is pleased to announce a new grant to support herpetological research by graduate students and foreign scientists. The grant is intended to defray the costs of transportation and lodging associated with visiting and using the collection. The Carnegie's herpetological collection contains more than 195,000 preserved specimens, including one of the largest collections of turtles, and extensive holding from the West Indies, México, South America, Spain, Africa, India, and the Philippines. Applicants should send the following, in duplicate: (1) a description of the proposed research (including its expected significance and the justification for visiting the Carnegie), not to exceed two pages; (2) literature cited; (3) budget; (4) CV. Students should also arrange for two letters of recommendation to be sent. Awards will be made twice a year. Deadline for application materials are 15 April and 15 November. Send applications to *Collection Study Grants in Herpetology, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, Pittsburgh, Pennsylvania 15213-4080, USA*. For more information contact *John Wiens (wiensj@clpgh.org; 412-622-5520; fax 412-622-8837) or Ellen Censky (censkye@clpgh.org; 412-622-3258).*

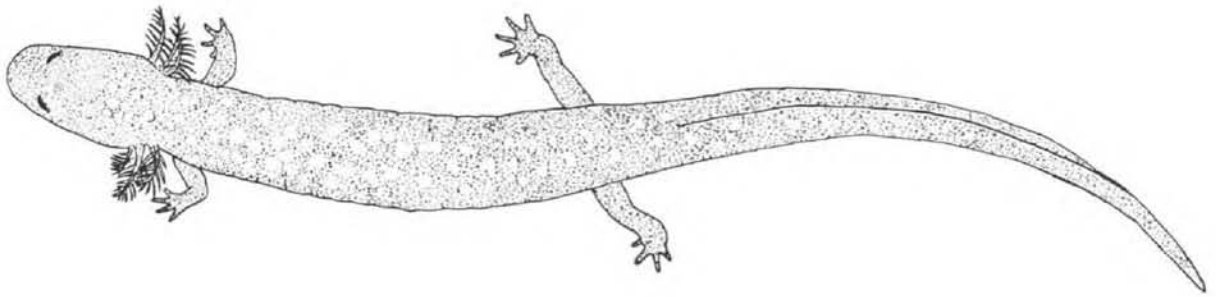
Zoo and Aquarium Directory

The 1995-96 Consortium of Aquariums Universities and Zoos Directory was published on 31 October 1995. The 159-page document contains valuable information for all zoo and aquarium professionals and includes listings of Species Survival Plan Coordinators and other important AZA (American Zoo and Aquarium Association) information. Network members from 25 countries have submitted information about their current activities, including field projects occurring in 75 countries. The directory is available at US$ 20 from *CAUZ Network Coordinator Donna Hardy, Department of Psychology, California State University, Northridge, California 91330, USA*. The URL on the World Wide Web is http://www.fhcrc.org/~ialwww/CAUZ/CAUZ.html.

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.



Proposals are due on 15 October 1996, with notification by 1 December 1996. Grantees are expected to complete their Academy visit by 15 September 1997. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

SENIOR HERPETOLOGISTS TO BE HONORED AT SSAR MEETING IN JULY

Roger Conant, Henry S. Fitch, Hobart M. Smith, Robert C. Stebbins, and Ernest E. Williams will be honored by the SSAR during its meeting at The University of Kansas in July 1996 (for details about the meeting, see *Herpetological Review*, 26(4):165–166, December 1995). These senior colleagues have had unusually productive careers and, indeed, they remain active.

The Welcoming Social, on the evening of Wednesday, July 24th, in the Kansas Union Ballroom, has been designated in their honor and **they plan to attend** to greet their many friends. This will be a unique opportunity for junior colleagues and students to meet these major figures in the field of herpetology.

A New Facsimile Reprint from the Society for the Study of Amphibians and Reptiles

HERPETOLOGY OF JAPAN
by LEONHARD STEJNEGER

With a New Introduction by MASAFUMI MATSUI

STEJNEGER'S BOOK, "HERPETOLOGY OF JAPAN AND ADJACENT TERRITORY," IS A recognized herpetological classic. It is "still the only complete treatment of the herpetology of Japan, and even today is an indispensable reference book" (from the new introduction). **Its geographic coverage is far greater than modern Japan and includes Taiwan, Korea, Manchuria, and adjacent coastal China, as well as easternmost Siberia.** Stejneger treats 156 species of amphibians and reptiles (13 salamanders, 36 frogs, 31 lizards, 62 snakes, and 14 turtles), including all marine species, and for each provides a complete synonymy, detailed descriptions of typical specimens, a discussion of variation, habitat, distribution, and a list of specimens with localities. Each species is illustrated, usually with multiple figures. There is an extensive, annotated bibliography, a gazetteer of localities, and an index.

Leonhard Stejneger (1851–1943), late curator of amphibians and reptiles at the National Museum of Natural History in Washington, was one of America's leading herpetologists. He authored many careful taxonomic studies on amphibians and reptiles from many parts of the world and wrote several other books, including "Poisonous Snakes of North America" (1895), "Herpetology of Porto Rico" (1904), and a series of checklists of the North American herpetofauna (1917–1943, with Thomas Barbour). Stejneger visited Japan three times and part of this book is based on his own field observations.

Masafumi Matsui (Kyoto University) provides commentary on Stejneger's work in Japan and updates his species names to current nomenclature. Matsui shows that Stejneger's 156 species today represent 180 taxa.

HERPETOLOGY *of* JAPAN

Specifications: 684 pages, portrait, map, 35 plates, 409 text figures, keys, index. Format 6 × 9 inches (15.5 × 23 cm). Clothbound. To be published September 1996. ISBN 0–916984–38–9.

Prices:	***Shipping:***
SSAR members *before publication* . . US$45.	In USA . . . . add US$3.
Institutions and Non-members . . . . . US$58.	Non-USA . . . add US$5.

Send orders to: Dr. Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, 3507 Laclede Avenue, Saint Louis, Missouri 63103, USA (*telephone*: area code 314, 977–3910 or –3916; *fax*: 314, 977–3658; *e-mail*: ssar@sluvca.slu.edu). Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks (include an additional amount to cover bank conversion charges) or by International Money Order. Orders may be charged to MasterCard or VISA (provide account number and expiration date). SSAR membership details and a complete list of Society publications can be obtained on request to Dr. Aldridge.

MEETINGS

Meetings Calendar

13–19 June 1996—76th Annual Meeting, American Society of Ichthyologists and Herpetologists, together with the 44th Annual Meeting of The Herpetologists' League, New Orleans, Louisiana, USA. Hosted by the University of New Orleans. Deadline for receipt of abstracts 1 April 1996. Contact: Bob Cashner, ASIH Local Committee Chair, Dept. Biological Sciences, University of New Orleans, New Orleans, Louisiana 70148, USA. Tel. (504) 286-6741; fax (504) 286-6121; E-mail RCCBS@UNO.EDU.

19–23 June 1996—Annual Meeting, The Society for the Study of Evolution and Society of Systematic Biologists. Washington University, St. Louis, Missouri, USA. SSB Symposium: "Morphological Data in Phylogenetic Analysis: Recent Progress and Unresolved Problems" (John Wiens, Organizer). Contact: Michael Ryan, Department of Zoology, University of Texas, Austin, Texas 78712, USA. Tel. (512) 471-5078. Meeting Web page at http://bio650.wustl.edu.

27–29 June 1996—20th Anniversary Meeting, International Herpetological Symposium. Sheraton Fiesta Hotel, San Antonio, Texas, USA. Focus on the herpetofauna of Madagascar and vicinity. Keynote speaker: W. Ronald Heyer. Banquet speaker: William W. Lamar. Contact: Davis Hulmes, 361 Van Winkle Avenue, Hawthorne, New Jersey 07506, USA. Tel. (201) 427-0768.

24–29 July 1996—39th Annual Meeting, Society for the Study of Amphibians and Reptiles. Hosted by The University of Kansas, Lawrence, Kansas, USA. *Refer to meeting announcement in this issue for details.*

1–5 August 1996—2nd International Conference on the Biology and Conservation of the South Asian Amphibians and Reptiles, University of Peradeniya, Sri Lanka. Contact: Anslem de Silva, Conference Director, Faculty of Medicine, University of Peradeniya, Sri Lanka. Tel. 94-08-88130; Fax 94-08-32572; e-mail: Anslem@Med.Pdn.ac.lk.

20–24 August 1996—2nd International Symposium and World Congress on the Preservation and Conservation of Natural Science Collections: "Natural Science Collections—A Resource for the Future." St. John's College, Cambridge, U.K. Contact: Chris Collins, Natural Sciences Congress '96, Geological Conservation Unit, Department of Earth Sciences, Downing Street, Cambridge, CB 2 3EQ, U.K. Tel. (0223) 62522; fax (0223) 60779.

24–27 August 1996—3rd Annual Conference of the Association of Reptilian and Amphibian Veterinarians, Saddlebrook Resort, Tampa, Florida, USA. Deadline for receipt of abstracts 15 April 1996. Contact: Wilbur Amand, VMD, P.O. Box 605, 1 Smithbridge Road, Chester Heights, Pennsylvania 19017, USA. Fax (215) 387-2165.

14–20 October 1996—4th Latin American Congress of Herpetology, University of Chile, Santiago de Chile, Chile. *Refer to meeting announcement below for details.*

2–10 August 1997—Third World Congress of Herpetology, Prague, Czech Republic. Contact: Zbynek Rocek, Congress Director, Department of Paleontology, Geological Institute, Academy of Sciences, Rozvojová 135, 165 00 Praha 6 – Suchdol, Czech Republic. Tel. (++42-2) 24311421; Fax (++42-2) 24311578; e-mail: rocek@gli.cas.cz. *Refer to meeting announcement in* Herpetological Review *27(1):4–5, March 1996 for details.*

Fourth Latin American Congress of Herpetology

The 4th Latin American Congress of Herpetology (4th CLAH) will be held at the University of Chile, Santiago de Chile, Chile, 14–20 October 1996. The official languages of the 4th CLAH will be Portuguese and Spanish. However, English and other languages will be accepted in workshops and poster presentations but they need to have an abstract in one of the official languages. For registration and additional information please contact: Dr. Alberto Veloso, Depto. de Ciencias Ecologicas, Facultad de Ciencias, Universidad de Chile, Casilla 653, Santiago, Chile; e-mail: veloso@abello.dic.uchile. For registration within the U.S. and Canada, please contact: Rafael de Sá, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA; e-mail: desa@urvax.urich.edu.

LEGISLATION & CONSERVATION

Call for information on the status of amphibians and reptiles. This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information especially on the State and Province level. Please send pertinent information to the Section Editor.

USA: Minnesota: Minnesota has issued draft revisions to its list of Endangered, Threatened, and Special Concern Species. The main changes from the previous official list include the elevation of the massasauga (*Sistrurus catenatus*) and the northern cricket frog (*Acris crepitans*) to Endangered and the timber rattlesnake (*Crotalus horridus*) to Threatened. The rattlesnake listings are significant in that they bring the status of these animals from bounty hunted to protected in seven years. The finalized, official list was expected at the end of March 1996. Submitted by John J. Moriarty, Suburban Hennepin Regional Park District, 12615 County Road 9, Plymouth, Minnesota 55441-1248, USA. For further information contact: *Richard J. Baker, Natural Heritage and Nongame Research Program, Minnesota DNR, Box 7, 500 Lafayette Road, St. Paul, Minnesota 55155-4007, USA. Tel. (612) 297-3764.*

USA: U.S. Fish and Wildlife Service: On 21 March 1996, the Office of Scientific Authority (OSA) issued a statement concerning the Proposed Rule to Export Box Turtles (*Terrapene*) from the United States in 1996 (Federal Register, vol. 61 [FR 61], no. 23, February 2, 1996, pp. 3894–3898). Specifically, the statement declares that the export quota of box turtles from Louisiana and the entire United States will be zero (0) in 1996. The Proposed Rule had requested information from the public and professional biologists on the proposal by Louisiana to export Gulf Coast box turtles (*Terrapene carolina major*) and three-toed box turtles (*T. c. triunguis*) in 1996. All box turtle species had previously been added to the CITES (Convention on International Trade in Endangered Species of Wild Fauna and Flora) Appendix II list at the Ninth Meeting of the organization in 1994. This listing was made based on documented long-term population declines in the United States. According to USFWS figures, approximately 26,000 *T. carolina* were exported from the U.S. in both 1992 and 1993 and 22,000 were exported in 1994 (FR 61). Louisiana's authorized export quota for 1995 was 9750 box turtles (FR 61), and by the end of 1995, 6115 box turtles had been exported of an estimated 13,300 harvested in the state (OSA, 21 March 1996). The deci-

sion by OSA to impose a zero export quota was made in response to numerous communications by scientists, conservation biologists, and the public who stated and agreed that the risk of serious population decline was great and that not enough information was available on the Louisiana populations to determine a sustainable level of harvest. In addition, available data from other turtle studies (e.g., Congdon et al. 1993, Conservation Biology 7:826–833) strongly suggest that the harvest of long-lived animals, in which the adults may take 10–20 years to reach maturity, coupled with relatively low fecundity, may not be sustainable. In conclusion, OSA believes that further scientific information on Louisiana's wild turtle populations and the implementation of a management plan will be necessary before future export quotas may be determined.

Section Editor's comment: I thank Allen Salzberg and Heather Kalb for constantly providing new information concerning this issue. I also find it encouraging that many persons took the time to respond to the Request for Information and Comment by the Office of Management Authority to convey their viewpoints and scientific information.—KAB

IUCN/SSC Re-Introduction Specialist Group

The IUCN/SSC Re-introduction Specialist Group (RSG) is a disciplinary group (as opposed to most Species Survival Commission (SSC) Specialist Groups which deal with a single taxonomic group). The RSG promotes the re-establishment or reinforcement of self-sustaining populations of plants and animals in the wild. The RSG has prepared official IUCN Re-introduction Guidelines, available upon request (see below). The RSG has an international network of members, publishes a bi-annual newsletter (*RE-INTRODUCTION NEWS*), and has a growing database of re-introduction projects worldwide. Persons involved in re-introduction efforts or those wishing more information may contact the RSG: *Pritpal S. Soorae, Technical Project Officer, IUCN/SSC Re-introduction Specialist Group, c/o African Wildlife Federation, P.O. Box 48177, Nairobi, Kenya. Tel. (254)-2-710367 or e-mail: awf.nrb@tt.gn.apc.org.*

Saltwater Crocodiles in Australia Stage Comeback; Reclassified as Threatened

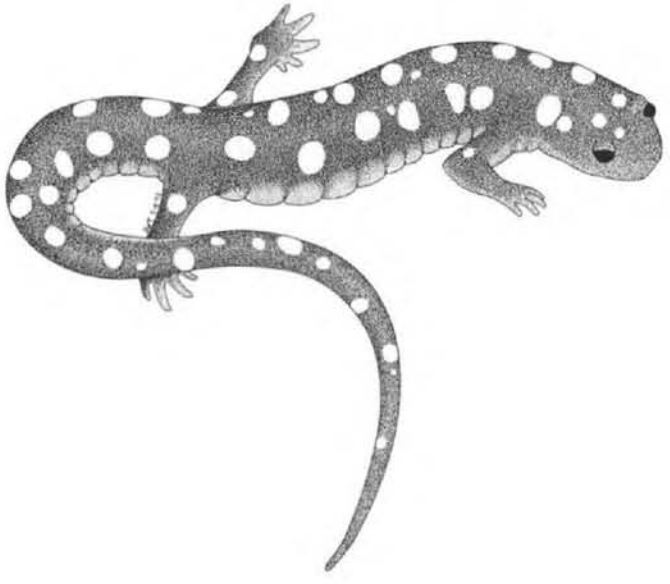
Rebounding from the effects of habitat loss and commercial exploitation, Australia's population of saltwater crocodiles (*Crocodylus porosus*) is being reclassified by the U.S. Fish and Wildlife Service from endangered to threatened, a less restrictive designation under the U.S. Endangered Species Act. Protective management strategies by the Australian government are in large part responsible for the crocodile's recovery. The Service said it is also issuing a special rule allowing the importation into this country of skins of these crocodiles as well as Nile crocodiles (*Crocodylus niloticus*), also listed as threatened, if certain requirements are met.

The saltwater crocodile was listed as endangered throughout its range (except the Papua New Guinea population which has never been listed) in 1979 because of severe habitat loss and the species' near extirpation due to illegal harvest to supply the international demand for products made from crocodiles.

"The remarkable recovery and reclassification of the saltwater crocodile demonstrates the effectiveness and flexibility of the U.S. Endangered Species Act," said Acting Service Director John Rogers. "Following the initial listing, habitat protection, trade restrictions, and the Australian state and federal governments' aggressive captive-breeding and ranching programs combined to bring back the species."

The reclassification to threatened status and the adoption of a special rule allowing commercial trade under certain conditions does not end trade controls for the species. The saltwater crocodile, along with the Nile crocodile, remains listed as an Appendix II species under the 130-nation conservation treaty, the Convention on International Trade in Endangered Species (CITES). This category allows commercial trade with appropriate export permits, issued by the country of origin, ensuring that such trade does not deplete wild populations.

The United States and other CITES member nations have been concerned about the commingling of legal and illegal crocodilian skins, especially in intermediary countries (those countries reexporting skins and products). At the ninth meeting of the Conference of Parties, held in Ft. Lauderdale, Florida, in November 1994, the CITES member nations adopted a crocodilian skin-tagging resolution. This resolution recommended the use of export tags by countries of origin (range countries) and administrative tracking measures in intermediary countries.



Provisions of the special rule established with this reclassification action are designed to support the tagging and tracking practices in the CITES resolution. Most CITES member nations trading in crocodilian skins and products implement the tagging and tracking practices properly. The special rule establishes procedures to prohibit such trade from any country not in compliance with the resolution.

"By allowing a controlled trade in legally harvested saltwater and Nile crocodile skins, meat, and products, we hope to provide other countries with incentives for conserving the species," Rogers said.

The saltwater crocodile is one of the world's largest reptiles, growing longer than 20 feet and weighing several hundred pounds. It ranges in coastal waters throughout Southeast Asia.

INSTITUTIONAL PROFILE

The University of Kansas: A Long-time Center of Herpetological Research and Training

LINDA TRUEB
and
WILLIAM E. DUELLMAN
Natural History Museum and Department of Systematics and Ecology
The University of Kansas, Lawrence, Kansas 66045-2454, USA

Sprawling over a wooded hill, Mount Oread, in the City of Lawrence (population 80,000), The University of Kansas (KU) is the academic home to more than 1200 faculty and 25,000 students. Denizens of the hill enjoy a wide range of scholarly interests and extracurricular activities, not the least of which is supporting the Jayhawk basketball team. However, herpetology at KU preceded basketball. The tradition of herpetological research at the university began with the founding of KU in 1866. One of the first four faculty members was Francis H. Snow. Although best known as an entomologist, Snow was in charge of the Cabinet of Natural History. He took students in the field throughout the state and other regions to collect specimens of plants and animals and survived a rattlesnake bite in the process. Later, as chancellor of the university, Snow was instrumental in convincing the state legislature to appropriate funds for the construction of the Natural History Museum. The museum was needed to house the accumulated collections and to be a showplace for the acclaimed Panorama of North American Wildlife prepared by the famous naturalist-explorer Lewis Lindsay Dyche, for whom the building is named. Snow also founded the State Biological Survey; most of the early herpetological specimens in the collections were acquired by personnel associated with that organization.

In 1908, Edward H. Taylor entered the university as an undergraduate; he participated in many field trips in Kansas and adjoining states and even managed to contract malaria on the plains. Upon his graduation in 1912, Taylor took a position in the Philippines, where he made extensive herpetological collections and became Director of the Bureau of Science in Manila. He returned to join the faculty of The University of Kansas in 1926. During his tenure, Taylor had an active group of graduate students. Notable among them were David M. Dunkle, Claude W. Hibbard, Hobart M. Smith, and Wilmer W. Tanner. In 1932, Taylor and Smith began a series of expeditions to Mexico. This event set a tempo for research in neotropical herpetology at KU and initiated a life-long career for Smith. During Taylor's tenure, research emphasized morphology, systematics and faunistic studies, such as the checklists of Mexican amphibians and reptiles (with Smith) and reviews of the herpetofaunas of Costa Rica and Thailand. Among the classic systematic studies were Smith's exhaustive treatise on *Sceloporus,* and Taylor's work on *Eumeces* and his monograph on caecilians.

In 1947, the university acquired a tract of 590 acres 7 miles northeast of Lawrence. This tract became the Natural History Reservation. The following year Henry S. Fitch joined the faculty as an assistant professor and superintendent of the reservation. Thus began nearly half a century of research on the biota of this mixed prairie and woodland area locally known as the "snake farm," resulting in some of the most thorough autecological studies ever completed on reptiles, e.g., Fitch's work on the blue-tailed skink (1954) and the copperhead (1963).

As the collections in the Natural History Museum grew, so did the curatorial staff. Taylor was named the first curator in herpetology in 1946; when he retired as curator in 1954, the herpetological collection contained more than 40,000 specimens. Between 1954 and 1959, John M. Legler was acting curator. By the time William E. Duellman became curator in 1959, the collection had grown to more than 51,000 specimens. In 1968, Joseph T. Collins was appointed as a technician in herpetology and ichthyology; in 1988 he relinquished his position in herpetology to work in various other capacities in the museum. Linda Trueb became the second curator in herpetology in 1975, and John E. Simmons was appointed collection manager in 1981.

Since 1960, the herpetological collections have grown steadily to the present number of 278,000 specimens. Most of the new material was acquired in the traditional way—through field work by the curators, staff, and students, principally in Latin America. However, the single largest accession (63,000 specimens) was the West Indian collection assembled by the late Albert Schwartz.

In addition to the usual alcoholic specimens, the KU collection contains a large numbers of amphibian larvae and skeletons, especially of anurans. Other important material associated with preserved voucher specimens includes color transparencies, tape recordings of anurans, histological preparations, and frozen tissues. Thanks to support from the National Science Foundation, in the last decade the entire collection has been checked for identifications and accuracy of data before an electronic hierarchical data base was established. The growth of the collections resulted in major space problems, which were relieved by the completion in the fall of 1995 of a new wing solely for the storage of alcoholic specimens.

The collection is widely used by the herpetological community. During the past five years, answers to 261 queries have resulted in the dissemination of 116,834 records of specimens and 324 loans of 11,205 specimens to investigators throughout the world. Within that same period, 144 visitors spent 659 days working in the collection.

In addition to curatorial facilities and collection storage, the Natural History Museum has histology and molecular laboratories, and photographic and sound-analysis facilities. The Division of Herpetology is equipped with a wide range of optical and computer equipment. A major asset is the herpetology library containing more than 3000 bound volumes and 27,000 reprints.

In addition to their curatorial responsibilities, Duellman is Director of the Center for Neotropical Biological Diversity, and Trueb is Scientific Editor of the museum publications. Nearly all of Duellman's research has dealt with aspects of the neotropical herpetofauna, ranging from a monograph on the hylid frogs of Middle America (1970) to the biology of the herpetofauna in Amazonian Ecuador (1978) and the evolution of marsupial frogs (in preparation). Working with specialists in other taxonomic groups in the neotropical biological diversity program, he is attempting to synthesize patterns of distribution of the neotropical biota. Trueb's research is focused on the morphology of amphibians and has ranged from detailed studies on the skulls of casqueheaded hylid frogs and the phylogeny of pipoid frogs (1988) to the relationships of the Lissamphibia (1991) to present endeavors on the integration of data from living and fossil taxa in a phylogenetic study of archeobatrachians. Duellman and Trueb combined efforts to produce the only existing compendium on amphibians, *Biology of Amphibians* (1986; reprinted in paperback in 1994). In his capacity as collection manager, Simmons has taken an active

role in the conservation of natural history collections, and is involved in several projects focused on the assessment, care, and maintenance of fluid-preserved specimens and natural history collection management.

A select number of herpetologists are research associates in the Division of Herpetology. These include Ana María Báez (Argentina), Carl Gans (USA), William W. Lamar (USA), John D. Lynch (USA), Michael J. Tyler (Australia), Alberto Veloso M. (Chile), and the late Werner C. A. Bokermann (Brazil).

Like other curators in the Natural History Museum, Duellman and Trueb have half-time academic appointments as professors in the Department of Systematics and Ecology. Duellman teaches courses in Biogeography and Reptile Biology, and with Trueb, Amphibian Biology. Trueb also teaches courses in Evolutionary Morphology and Scientific Illustration. Henry Fitch, Professor Emeritus, continues to provide limited guidance to students.

The University of Kansas has maintained a strong graduate program in herpetology. Graduate students have come from throughout the USA, including Puerto Rico, as well as many foreign countries—Argentina, Brazil, Burma, Chile, Colombia, Ecuador, Germany, India, Mexico, Peru, Venezuela, and Zambia. Doctoral dissertations by students in the Natural History Museum have reflected a wide variety of research carried out in many parts of the world. These include ecological studies such as reproductive strategies of tropical frogs (Martha L. Crump, 1974), population biology of the brown soft-shelled turtle (Michael V. Plummer, 1975), and foraging ecology of garter snakes (Richard A. Seigel, 1984). Biogeographic studies include the ecobiogeography of the herpetofauna of the Yucatan Peninsula (Julian C. Lee, 1977), late Pleistocene herpetofauna of Puerto Rico (Gregory K. Pregill, 1979), and biogeography of lizards in the Samoan Islands (Terry D. Schwaner, 1979). Systematic studies varied from the systematics of *Rhadinaea* (Charles W. Myers, 1970) and phylogenetic relationships among iguanian lizards (Darrel R. Frost, 1985) to molecular studies such as systematics of New World *Rana* (David M. Hillis, 1985) and phylogenetic relationships among desmognathine salamanders (Tom A. Titus, 1992). Also, numerous undergraduate students have carried out research in herpetology; among these are Pere Alberch, Neil B. Ford, Kevin R. Toal III, and John J. Wiens.

Present graduate student dissertation research includes the population biology of the Puerto Rican frog *Eleutherodactylus cooki* (Patricia A. Burrowes), the phylogenetic relationships among toads of the genus *Atelopus* (Luis A. Coloma), phylogenetic relationships of megophryine frogs (Anne Maglia), heterochrony and miniaturization in anurans (Daniel J. Meinhardt), systematics and biogeography of toads of the *Bufo valliceps* group (Joseph R. Mendelson III), dentition and feeding in frogs (Jeffrey R. Parmelee), phylogenetic relationships of casque-headed treefrogs (Helio da Silva), and developmental osteology and phylogenetic relationships of ceratophryine frogs (Erik R. Wild).

In 1974, the Kansas Herpetological Society was founded in Lawrence by Joseph T. Collins and Eric Rundquist. This organization has grown to 260 members, many of whom participate in an annual meeting and numerous field trips that are designed to increase knowledge of occurrence and abundance of amphibians and reptiles in Kansas. Members provide voucher specimens for the Natural History Museum; these and other accumulated data are documented in the Newsletter of the Society and have provided distributional data for the three editions of *Amphibians and Reptiles in Kansas* by Joseph T. Collins.

The diversity of research by staff and students in the Division of Herpetology has resulted in 233 publications in the past decade. These are distributed to herpetologists worldwide; currently 402 persons are on the mailing list. The staff at KU have long taken active roles in herpetological societies. Both Edward H. Taylor and Linda Trueb served as presidents of the American Society of Ichthyologists and Herpetologists; William E. Duellman was president of the Herpetologists' League, and Joseph T. Collins was president of the Society for the Study of Amphibians and Reptiles. The annual meeting of the American Society of Ichthyologists and Herpetologists was held at KU in 1965, as was the combined annual meeting of the Herpetologists' League and the Society for the Study of Amphibians and Reptiles in 1977. All of us at The University of Kansas look forward to hosting the annual meeting of the Society for the Study of Amphibians and Reptiles in 1996.

Hobart Smith (left), University of Kansas alumnus, and Henry Fitch (right), Professor Emeritus at KU. Both will be honored at the 1996 SSAR Annual Meeting. Photo by Larry Miller, courtesy of Joseph T. Collins.

CURRENT RESEARCH

The purpose of **Current Research** is to present basic summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA; e-mail: herpbooks@sisna.com. Comments and suggestions are also welcome.

The current contents of several herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are being listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Systematics

Ctenoblepharys adspersa is a highly derived arenicolous lizard that inhabits the sandy coast of central Peru. Etheridge recently examined this species and its relationship to others in the subfamily Liolaeminae. In addition to a redescription of *C. adspersa*, a taxonomic history of the genus is presented.

ETHERIDGE, R. 1995. Redescription of *Ctenoblepharys adspersa* Tschudi, 1845, and the taxonomy of Liolaeminae (Reptilia: Squamata: Tropiduridae). Am. Mus. Novit. (3142):1–34.

Ctenosaura

Gunther Köhler recently published several papers on the spiny-tailed iguanas of the genus *Ctenosaura*. In addition to field studies, Köhler described two new species. The papers listed below are a selection of his recent work; other papers are available.

KÖHLER, G. AND K. KLEMMER. 1994. Eine neue schwarzleguanart der gattung *Ctenosaura* aus La Paz, Honduras [A new species of the genus *Ctenosaura* from La Paz, Honduras]. Salamandra 30(3):197–208.

KÖHLER, G. 1995. Eine neue art der gattung *Ctenosaura* (Sauria: Iguanidae) aus dem südlichen Campeche, Mexico [A new species of the genus *Ctenosaura* from southern Campeche, Mexico]. Salamandra 31(1):1–14.

KÖHLER, G. 1995. Freilanduntersuchungen zur morphologie und Ökologie von *Ctenosaura bakeri* und *C. oedirhina* auf den Islas de la Bahia, Honduras, mit bemerkungen zur schutzproblematik [Field studies on morphology and ecology of *Ctenosaura bakeri* and *C. oedirhina* on the Islas de la Bahia, Honduras, with notes on conservation status]. Salamandra 31(2):93–106.

Physiology of Digestion

The digestive physiology and energy requirements of eating were examined in two species of snake. Both *Crotalus cerastes* and *Python molurus* fast for long periods between meals and undergo rapid physiological change after eating. Secor and colleagues examined these changes and the energy budget associated with digestion in two recent papers.

SECOR, S. M., E. D. STEIN, AND J. DIAMOND. 1994. Rapid upregulation of snake intestine in response to feeding: a new model of intestinal adaptation. Am. J. Phys. 266 (Gastrointest. Liver Physiol. 29):G695–G705.

SECOR, S. M., AND J. DIAMOND. 1995. Adaptive responses to feeding in Burmese pythons: pay before pumping. J. Exp. Biol. 198:1313–1325.

Amphibian Declines

In previous studies Blaustein and colleagues have examined the possible role of UV-B irradiation and a fungus in the decline of amphibians in the Pacific Northwest (USA). Recently Kiesecker and Blaustein presented evidence of synergistic effects of these two factors on the mortality of amphibian embryos.

KIESECKER, J. M., AND A. R. BLAUSTEIN. 1995. Synergism between UV-B radiation and a pathogen magnifies amphibian embryo mortality in nature. Proc. Nat. Acad. Sci. 92(24):11049–11052.

Anuran Vertebral Morphology

During the last five years the Morphology Research Group of St. Petersburg State University (Russia) has published several papers on anuran vertebral morphology. The group's research interests include form transformation during ontogeny and phylogeny, significance of variability and anomalies for evolution, morphogenetic mechanisms determining normal and abnormal development, methods of analysis of variability, and bioindication.

Some recent publications from the group are listed below. Reprints can be obtained by writing: Morphology Research Group, Department of Vertebrate Zoology, Faculty of Biology and Soil Science, St. Petersburg State University, Universitetskaya nab. 7/9, 199034, Russia, or e-mail: Irene@isav.usr.pu.ru. The group is seeking collaborators and reprints of morphological studies.

DANILOV, I. G. 1995. Analysis of variability of the vertebral column in some Palearctic ranids. Abstracts, 8th O.G.M. of S.E.H., Bonn, Germany, 23–27 August 1995, p.48.

KOVALENKO, E. E. 1992. The anomalies of the vertebral column in Anura. St. Petersburg University Press, 142 pp. [In Russian]

KOVALENKO, E. E. 1994. The variability of anuran sacrum: structure analysis in the whole spectrum of its possibility. ICVM-4 Abstracts. J. Morphol. 220(3):362.

KOVALENKO, E. E. 1994. The compound sacrum in individual variability of common platanna (*Xenopus laevis*). Russian J. Herpetol. 1(2):172–178.

KOVALENKO, E. E., AND I. G. DANILOV 1994. Rare variants of abnormal structure of the vertebral column in Anura. Vestn. S. Pb. Univ., Ser. 3 Biologia, No. 3, pp. 10–24. [In Russian]

KOVALENKO, E. E., AND S.E. DANILEVSKAYA 1993. On unique forms of anomalous sacral structure in tailless amphibians. Russian J. Herpetol. 1(1):30–36.

KOVALENKO, E. E., AND T. A. BORDUKOVA 1995 The variance of the sacrum form in ontogeny of common platanna *Xenopus laevis* (Anura: Pipidae). Vestn. S. Pb. Univ. Ser. 3 Biologia, No. 2, pp.18–31. [In Russian]

MALASHICHEV, Y. B. 1995. Qualitative variability analysis of the sacro–coccygeal part of the vertebral column in some *Bombina* species. Abstracts. 8th O.G.M. of the S.E.H., Bonn, Germany, 23–27 August 1995, pp. 82–83.

Intraspecific Venom Evolution

Venom composition within snake species can show considerable geographic variation. The underlying causes of this phenomenon have never been explained. Daltry et al. examined the venom of the southeast Asian pit-viper *Calloselasma rhodostoma* in relation to diet, gene flow, and phylogeny and found that geographic differences in diet were closely associated with differences in venom composition. The other two factors appeared not to be related to venom composition.

Calloselasma rhodostoma. Photo courtesy of Wolfgang Wüster.

DALTRY, J. C., W. WÜSTER, AND R. S. THORPE. 1996. Diet and snake venom evolution. Nature 379(6565):537–540.

New Publication Series

The Oklahoma Museum of Natural History has begun an Occasional Papers series. The inaugural paper, by Laurie J. Vitt, examines the ecology and interrelationships of 13 carnivorous lizard species in the semiarid caatinga of Brazil. For more information about the series, or to obtain copies, write to: Oklahoma Museum of Natural History, 1335 Asp Avenue, Norman, Oklahoma 73019–0606, USA.

VITT, L. J. 1995. The ecology of tropical lizards in the caatinga of northeast Brazil. Occ. Pap. Oklahoma Mus. Nat. Hist. (1):1–29.

Russian Journal of Herpetology

Russian Journal of Herpetology is an international, multidisciplinary journal and publishes articles covering both basic and applied research on recent and fossil amphibians and reptiles. All aspects of herpetology including systematics, distribution, speciation, phylogeny, morphology as well as behavior, ecology, and toxinology of amphibians and reptiles will be presented.

Of particular emphasis is the conservation of species of amphibians and reptiles, their associations and habitats. Although much attention is given to fundamental research, papers devoted to breeding in captivity and propagation of amphibians and reptiles will be welcomed and presented in a special part of the journal.

The ultimate aim of the journal is to provide an effective medium for communication of the latest and best scientific information from the expanding, interdisciplinary, and international scientific community focusing on new methods and ideas in progress and to promote cooperation between Russian and foreign scientific and commercial organizations.

Subscription Information: One volume per year, in two issues. Subscription price for 1996: US$ 84 (for libraries), US$ 44 (for individuals), US$ 75 (Supporting Membership).

Because of the difficulty in sending money to banks in Russia, the Museum of Vertebrate Zoology will handle membership fees for the journal. Checks for membership in this society and subscription to the journal should be made out to RJH and mailed to: *Russian Journal of Herpetology*, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA. Checks must be in $US drawn on a bank with an office in the USA. International money orders (such as issued in Japan) can be accepted.

Because of the difficult economic situation in Russia, the Russian Herpetological Society cannot survive without foreign memberships. The journal is provided free of charge to herpetologists in the former USSR. There are now less than 100 foreign members in the society. Each issue of RJH costs about $3000 to produce. If you are associated with a museum or university, perhaps you can ask your library to subscribe.

Contents of Volume 2 are:

SCHNEIDER, H., AND E. M. EGIASARYAN. 1995. The mating call of the green toad, *Bufo viridis viridis* (Anura, Amphibia), in Kazakhstan. Russian J. Herpetol 2(1):1–4.

GOLUBEV, M. L., AND E. A. DUNAYEV. 1995. *Phrynocephalus nasatus* (Reptilia, Agamidae), a new species of toad agama from western China. Russian J. Herpetol 2(1):5–9.

CARRETERO, M. A., AND G.A. LLORENTE. 1995. Reproduction of *Acanthodactylus erythrurus* in its northern boundary. Russian J. Herpetol 2(1):10–17.

TATARINOV, L. P. 1995. A new ictidosuchid *Karenites ornamentatus* (Theriodontia) from the Upper Permian of the Kotel'nich Locality in the Kirov Region. Russian J. Herpetol 2(1):18–33.

LITVINCHUK, S. N., AND L. J. BORKIN. 1995. First record of the Danube newt, *Triturus dobrogicus*, in Moldavia. Russian J. Herpetol 2(2):176–177.

ORLOV, N. L. 1995. Rare snakes of the mountainous forests of northern Indochina. Russian J. Herpetol 2(2):179–183.

POINT OF VIEW

Tail and Hand Waves: A Come-on for Predators?

WILLIAM E. MAGNUSSON
Coordenação de Pesquisas em Ecologia
Instituto Nacional de Pesquisas da Amazônia
Caixa Postal 478, 69011-970 Manaus AM, Brasil
e-mail: bill@cr-am.rnp.br

Werner (1995) noted that tail waving has a long history of description in the literature, and in the same issue, Bedford (1995) describes tail waving in *Carlia*. Tail waving has been assigned a role in prey capture (Perez-Mellado 1994) and has been suggested as a tactic to divert predator attacks from the head region (e.g., Fitch 1954; Vitt and Cooper 1986). Here, I would like to advance a third hypothesis that is a more likely reason for the evolution of the trait, even though it may have acquired secondary functions.

Movement attracts the attention of visual predators (Cushing 1939; Gluesing 1983). It is so notable that many species of active lizards appear to have abandoned crypsis entirely, at least in the males, and developed bright coloration which is presumably important in sexual interactions. Sit-and-wait species usually have flash colors which are used only during courting or territorial interactions. Tail waving to distract a predator from the head obviously would only be of benefit after detection by the predator. Attracting the predator so that it could bite your tail would seem a rather unlikely adaptation. Species that show ontogenetic shifts in tail color (e.g., Vitt and Cooper 1986) may show ontogenetic differences in activity (e.g., Fitch 1954).

Most lizards that use tail waving do so in the intervals between bouts of walking or running. I suggest that this has evolved as a stimulus for predators. Not only are moving lizards easily detected by predators, they are also essentially blind during movement due to the relative motion of the background (see review in Fleishman 1986). I have observed yellow-faced whip snakes (*Demansia psammophis*) stalking copper-tailed skinks (*Ctenotus taeniolatus*) in Australia and their ecological equivalents, *Mastigodryas boddaerti* and *Cnemidophorus lemniscatus* in Brazil. In each case, the snake follows the lizard while it is moving and remains motionless while the lizard is motionless. The lizards are attentive and appear to be scanning for predators while stationary. My own experience stalking lizards, feral buffaloes, and kangaroos convinces me that the tactic is effective.

It would obviously be advantageous for the lizard to maintain movement, which would keep the predator in motion, while maintaining the head motionless so that it can detect movement. That is exactly what waving the tail between bursts of walking or running does. Neither of the two wide-foraging lizards mentioned above has a flexible tail, but *C. lemniscatus* waves one, or occasionally both forelegs while maintaining the head immobile. A similar behavior has evolved, presumably independently, in the agamid *Amphibolurus barbatus*. In contrast to amphibians (Bavetz 1994), the lizards do not wave their legs when feeding.

This hypothesis requires further investigation but I believe that it is a viable alternative to hypotheses that suggest that the tail is mainly a food gathering or an expendable diversionary organ.

THE GARTER SNAKES
Evolution and Ecology
By Douglas A. Rossman, Neil B. Ford, and Richard A. Seigel

Volume 2 in the Animal Natural History Series

"Garter snakes! And more garter snakes! In fact, all known species of garter snakes are examined in this keystone coverage of the ecology and evolution of the genus. With their insights and augmentation to current knowledge Rossman, Ford, and Seigel unequivocally establish garter snakes as a group we know more about than any other diverse genus of snakes in the world. GARTER SNAKES will set the herpetological standard for works of this type."—**J. Whitfield Gibbons**, University of Georgia.

The first comprehensive review of the genus *Thamnophis* in nearly ninety years, this up-to-date, appealing book, written by the world's leading authorities, contains 88 color plates, 31 black-and-white figures, 28 maps, and 4 tables.

Although the debate continues on the relative roles of natural fluctuations and anthropogenic influences in recently observed amphibian population declines (Blaustein 1994; McCoy 1994; Pechman et al. 1991; Pechman and Wilbur 1994; Travis 1994), many species are clearly demonstrating local extinctions and large-scale declines (Blaustein and Wake 1990; Blaustein et al. 1994b; Fellers and Drost 1993; Hayes and Jennings 1986; Jennings 1988). Causes of these declines can be placed in two broad categories: direct habitat degradation (Blaustein et al. 1994b), and more nebulous large-scale environmental changes and contamination (e.g., airborne pollutants, acid precipitation, ultraviolet radiation) (Blaustein et al. 1994a; Dunson and Wyman 1992; Fellers and Drost 1993; Hagstrom 1977; Harte and Hoffman 1989).

Dams and water diversion projects have been proposed as causes of declines of many native frogs (Hayes and Jennings 1986; Jennings 1988; Moyle 1973), but the effects of these projects have not been quantitatively evaluated. Water diversions also have been implicated in region-wide declines of anadromous fish in the Pacific Northwest (Moyle and Williams 1990; Nehlsen et al. 1991) and are documented to adversely affect riverine macroinvertebrates (Petts 1984). Impacts to fish include loss and degradation of habitat because of reservoir filling and downstream changes in river morphology along with detrimental off-season and fluctuating water releases (Burt and Mundie 1986; Petts 1984). A recent petition to list the arroyo southwestern toad (*Bufo microscaphus californicus*) as endangered indicated that impoundments associated with dam construction have caused a 40% loss in the original habitat of this toad. In addition, it was suggested that habitat quality downstream of dams has been severely compromised by changes in water temperatures, riparian vegetation, and habitat stability (Federal Register 1993). Our study provides information on both direct and indirect effects of a dam on the foothill yellow-legged frog (*Rana boylii*) in a northwestern California river system.

Rana boylii is generally found in association with stream riffles that have rocky substrates and partly shaded banks (Hayes and Jennings 1988; Moyle 1973; Zweifel 1955). This frog ranges from northern Baja California, Mexico (Loomis 1965) to central Oregon, west of the Sierra Nevada and Cascade crests. *Rana boylii* is currently listed as a Species of Special Concern in California (Laudenslayer et al. 1991) and is also a candidate for Federal listing (Federal Register 1994). The most notable declines are in southern California and the west slope drainages of the Sierra Nevada and southern Cascade Mountains (Jennings and Hayes 1994; Leonard et al. 1993).

Our objectives were: (1) to describe the changes in *Rana boylii* breeding habitat in a dammed river prior to and some years following dam construction, and (2) to document the effects of the timing of water releases from the dam on the reproductive ecology of this population.

Our study took place on the main stem of the Trinity River, in Trinity County, California, USA, and covered the 63 km of river from Lewiston Dam (near Lewiston, California) downstream to the confluence with the North Fork Trinity, near Helena, California (elevation 420–550 m). Construction of two dams, an upper (Trinity) and a lower (Lewiston), was completed in 1963. At Helena, this river drains an area of 2968 km^2. Before dam construction the river had an average yearly (water year; Oct–Sept) discharge of 1.2 million acre-feet at Lewiston. During the four years of our study, the yearly discharge ranged from 270,800 to 367,600 acre-feet at Lewiston. The basin surrounding our study reach is 52% public land (USDA Forest Service and USDI Bureau of Land Management) and 48% privately owned. Land use activities within this watershed include logging and associated road building, recreation, and widely scattered home construction. Portions of river channel and adjacent areas were mined in the early to mid-1900's.

Since 1984, the USDI Fish and Wildlife Service, in cooperation with the USDI Bureau of Reclamation (the dam administrator), has been conducting a flow evaluation study on the main stem of the Trinity River. Water has been released at varying levels above base flow (8.5 m^3/sec [cms]), each spring in order to facilitate migration of wild and hatchery-raised anadromous fish and to permit evaluation of fish habitat availability and changes as a function of discharge. The timing of these high flow releases has been influenced by many factors, though efforts have been made to mimic historical flow release patterns (Trinity River Restoration Program 1994).

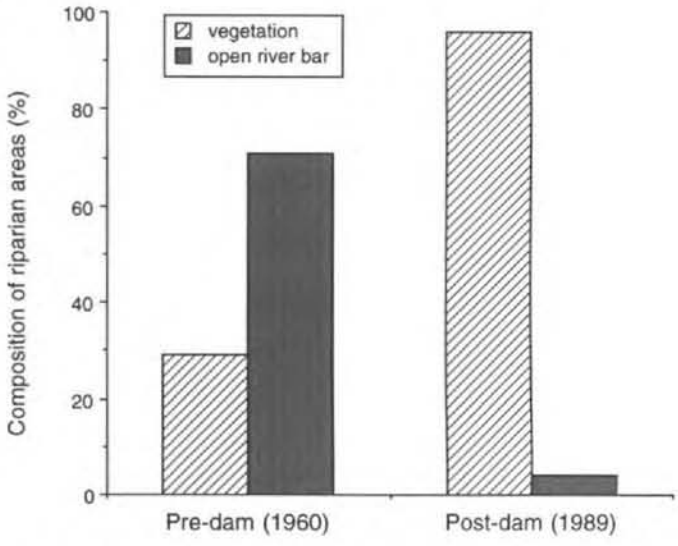

FIG. 1. Riparian habitat composition before (1960) and 26 years after (1989) construction of Trinity and Lewiston Dams on the main stem Trinity River. Estimates were derived from GIS analysis of aerial photographs.

A geographical information system (GIS) was used to analyze amount and distribution of riparian habitats prior to and following construction of the dams. Aerial photographs taken before (1960) and 26 years after (1989) the construction of the dams were used to derive estimates of the areal extent of four riparian habitats: (1) unvegetated rocky areas, (2) willow stands, (3) wil-

low/alder mixed stands, and (4) alder/cottonwood stands. We used U.S. Geological Survey (USGS) records of flow releases at Lewiston and in an undammed tributary stream within our study area, Grass Valley Creek, California, to determine the timing and magnitude of discharges during our study. Values for discharge at Helena (the lower end of our study area) were derived by extrapolating tributary flows from Grass Valley Creek to the drainage area between Lewiston and Helena.

Field surveys of all potential breeding habitat were conducted from 1991–1994 along the study reach described above. Designation of potential breeding habitat was based on literature accounts of suitable habitat (Fuller and Lind 1992; Hayes and Jennings 1988; Kupferberg, in press; Zweifel 1955) and our experience with this species in other drainages in northwestern California. Potential breeding habitat, for riverine environments, was defined as low-velocity (0.0–0.21 m/sec), shallow water (8–40 cm), with rocky substrates, adjacent to sparsely vegetated, gravel/cobble bars (hereafter referred to as bars). Bars are formed through the natural meandering process of rivers and are areas of repeated sediment deposition and erosion; usually they occur on the inside of meander bends (Leopold et al. 1964). We sampled only those bars (= sites) that were at least 10 m long and composed of coarse gravel (>32 mm diam: Platts et al. 1983) or larger substrates. Many of the bars are no longer geomorphologically active because of decreased flows. In these cases, only the sparsely vegetated portions of bars were surveyed and the heavily vegetated and steeply sloped portions were omitted because of poor habitat quality. In 1993 and 1994, we also surveyed several "bank feathering" restoration projects that were within our study reach. These feathering projects are designed to restore river bars to their historic form. Through removal of riparian berms and encroaching vegetation, river banks are mechanically recontoured to form a gentle slope and provide shallow, low water-velocity habitats (Trinity River Restoration Program 1994).

Several surveys were conducted throughout the breeding and rearing season of *Rana boylii* on the main stem Trinity River in 1991–1994 (Table 1). Two surveys were conducted each spring in 1991–1993 and one in 1994. Twenty-five to 33 natural bars were surveyed each year. In addition, one bank-feathering project was surveyed in 1993 and five more were surveyed in 1994. Surveys were timed to coincide with the peak of breeding activity each year, if possible, and were carried out from late April through

TABLE 1. *Rana boylii* reproductive ecology on the main stem Trinity River, between Lewiston and Helena, in northwestern California, 1991–1994.

1. ( ) = larvae only found at this site.
2. Includes one recently completed bank feathering restoration project site and two natural sites not surveyed in previous years.
3. Includes five recently completed bank feathering restoration project sites not surveyed in previous years; 10 of 24 egg masses were laid at these sites.

June. At least one mid-summer survey (late July/early August) was conducted to search for larvae. We also conducted at least one survey at known breeding sites, immediately following high-flow releases from the dam to track egg mass survival. In 1993, high-flow releases from Lewiston Dam in April were followed by a long period of rain and natural high flows from tributary input in May and early June; as a result we surveyed substantially later than in other years. At each bar site, egg masses, juveniles, and adult frogs were counted. The length of each bar was measured by pacing so that estimates of frogs and egg masses per linear meter of habitat could be derived. We also examined historical locality records for *Rana boylii* to qualitatively assess the distribution of this species in the Trinity Basin prior to dam construction on the main stem.

Water releases since construction of the dams have been 10–30% of pre-dam flows, based on both total yearly volume and magnitude of periodic high flows (Trinity River Restoration Program 1994; USGS records 1991–1994). Within our study area, vegetation covered less than 30% of the pre-dam riparian area and more than 95% of the post-dam area. Open bars made up 70% of the pre-dam riparian area and only 4% of the post-dam area (Fig. 1). This constitutes a loss of 94% of bar habitat, and potential breeding habitat for *Rana boylii*. Encroachment by riparian vegetation has resulted in the development of stable sandy berms, forcing the river into a narrower and deeper channel that lacks habitat complexity. Other changes seen along the main stem Trinity include loss of seasonally flooded marshes and high-flow side channels, filling of pools with fine sediments, lowered water temperatures, and riffle sedimentation (Petts 1984).

Historical records (Bury 1967; Museum of Vertebrate Zoology, University of California at Berkeley) demonstrate that *Rana boylii* occurred on the main stem Trinity and in many tributary streams, though relative abundance could not be gauged from these records. Initial surveys indicated that there were few *Rana boylii* in the upper portion of our study area and that the lower section had more potential breeding habitat due to the more natural flow conditions created by tributary streams; subsequently we surveyed only the lower 22.5 km. Of the 25–39 bar and bank feathering sites searched, 7–10 had egg masses annually. Total egg mass counts over four years ranged from 21–31 annually in 22.5 km (Table 1).

During the four years we tracked breeding relative to the tim-

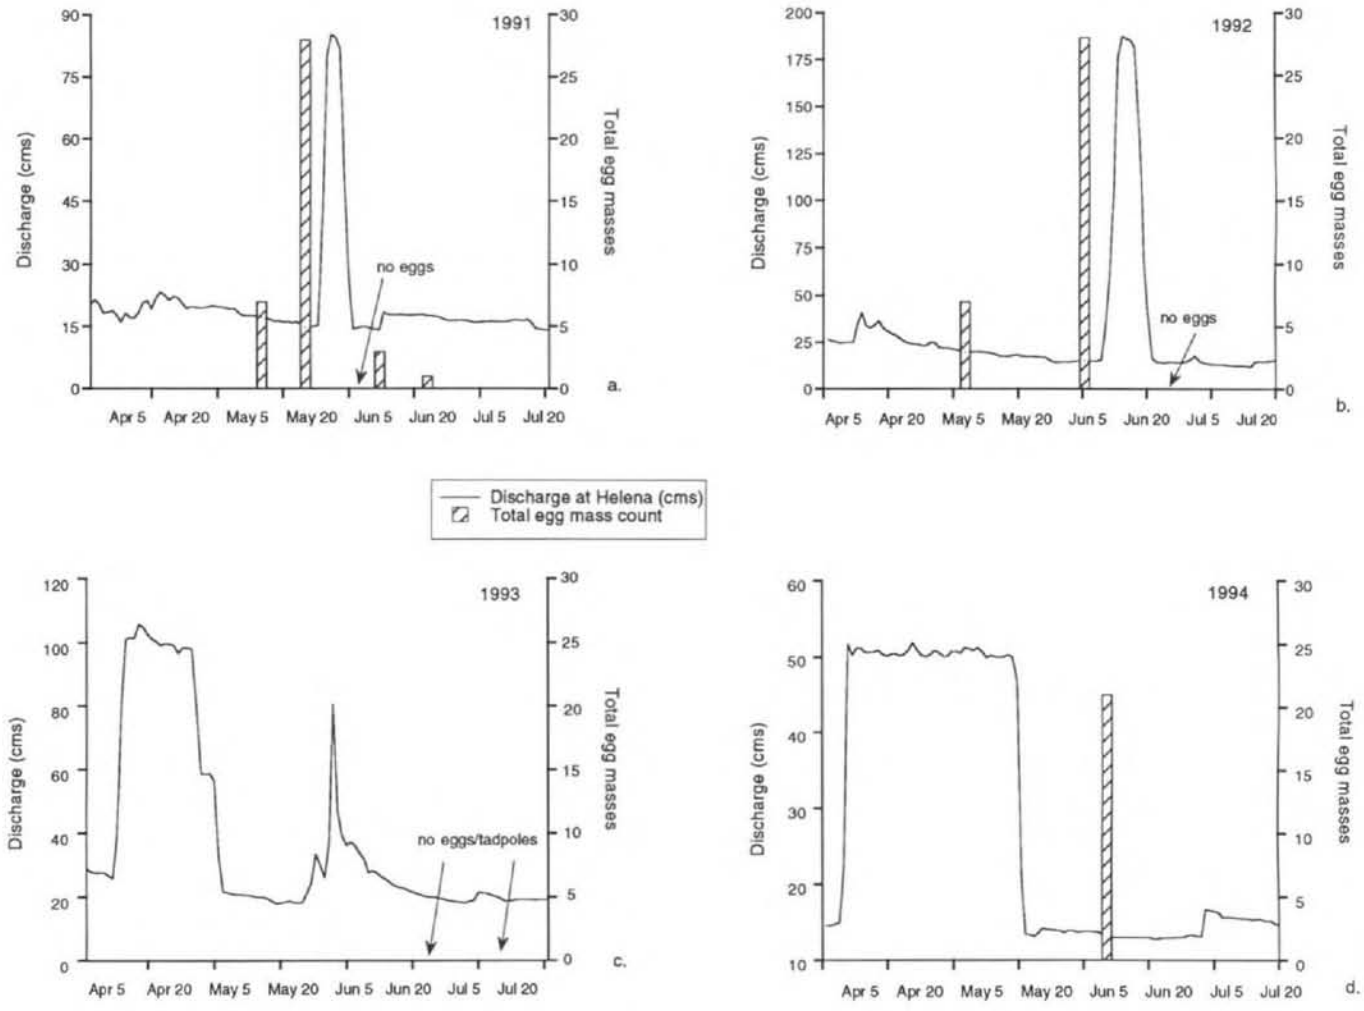

FIG. 2. Chronology of foothill yellow-legged frog (*Rana boylii*) breeding and egg mass abundance as documented by river shoreline surveys, and discharge (in cubic meters per second [cms]) of the main stem Trinity River at Helena for (a) 1991, (b) 1992, (c) 1993, and (d) 1994.

ing and magnitude of flow releases on the main stem, we found significant negative impacts in 1991 and 1992 and undetermined impacts in 1993 and 1994. In 1991 and 1992, all egg masses laid before high flow releases were lost (Table 1, Fig. 2a & b). In 1991, three egg masses were laid at one site after the largest flow release, and a second flow increase from 14 to 18 cms eliminated two of the three (Fig. 2a). Mid-summer surveys of breeding sites indicated that larvae survived after the high flows only at sites where egg masses had hatched prior to high-flow releases. In 1991, three to four larvae were found at two of the seven known breeding sites. Of the 10 known 1992 breeding sites, three sites had one larvae each and three sites had two, eight, and fifteen larvae. In 1993 we found no egg masses or larvae during spring surveys, though surveys were conducted later than in previous years. However, we did find larvae at several sites during mid-summer surveys. We do not know whether these larvae were missed during spring surveys or whether they moved into the main stem from unsurveyed tributary streams. The only year in which a substantial proportion of egg masses and larvae appear to have survived to metamorphosis was 1994. High-flow releases were earlier in 1994, and most breeding activity occurred after these releases (Fig. 2d). At one site visited biweekly through late October 1994, all life stages were seen, though no more than two metamorphic individuals were seen on any given day.

Though downstream effects of dams can be quite variable, several changes appear consistent across most dammed systems. For example, peak flood flows are decreased and year-round flows are typically lower (Ligon et al. 1995; Williams and Wolman 1984). Sediment concentrations and suspended sediments decrease substantially for many miles downstream and bed material typically becomes more coarse (Ligon et al. 1995; Williams and Wolman 1984). In general, the areal extent of riparian vegetation increases below dams as a result of reduced flows and lack of scouring floods; this was the case on the Trinity (Fig. 1, Petts 1984). In addition, riverine species experience direct habitat loss as a result of reservoir filling. Brode and Bury (1984) documented a potential loss of more than 50 km of stream habitat for *Rana boylii* inhabiting the area of a proposed dam and reservoir.

On the Trinity River, two aspects of the dams are having significant impacts on the *Rana boylii* population. First, river morphology has changed significantly since flows became controlled in 1963, and as a result a significant amount of breeding habitat has been lost (Fig. 1). Data from a comparably-sized undammed river fork in the same system (the South Fork Trinity) demonstrated that both the number of potential sites and the total number of egg masses were substantially higher on this fork than in our main stem study area. We found 548–730 egg masses annually, at 81–87 sites in 15 km during three years of surveys from 1992–1994 on the undammed fork (unpublished data). The second factor is the timing of high-flow releases from the dam. In at least two of the last four years, entire cohorts of *Rana boylii* were lost along our main stem study reach because of unseasonal high flow releases (Fig. 2). Kupferberg (in press) demonstrated that survival of *Rana boylii* egg masses in a natural river was dependent on channel morphology and timing of egg deposition, during both increases and reductions in flows.

Other dam-related factors that may influence the breeding ecology of *Rana boylii* in this river are water temperature, exotic species, and changes in prey base. To accommodate fisheries requirements, water temperatures are kept artificially low (relative to pre-dam conditions and present conditions on other local rivers) using higher than normal releases in mid-summer; this may retard development of eggs and larvae (Duellman and Trueb 1986).

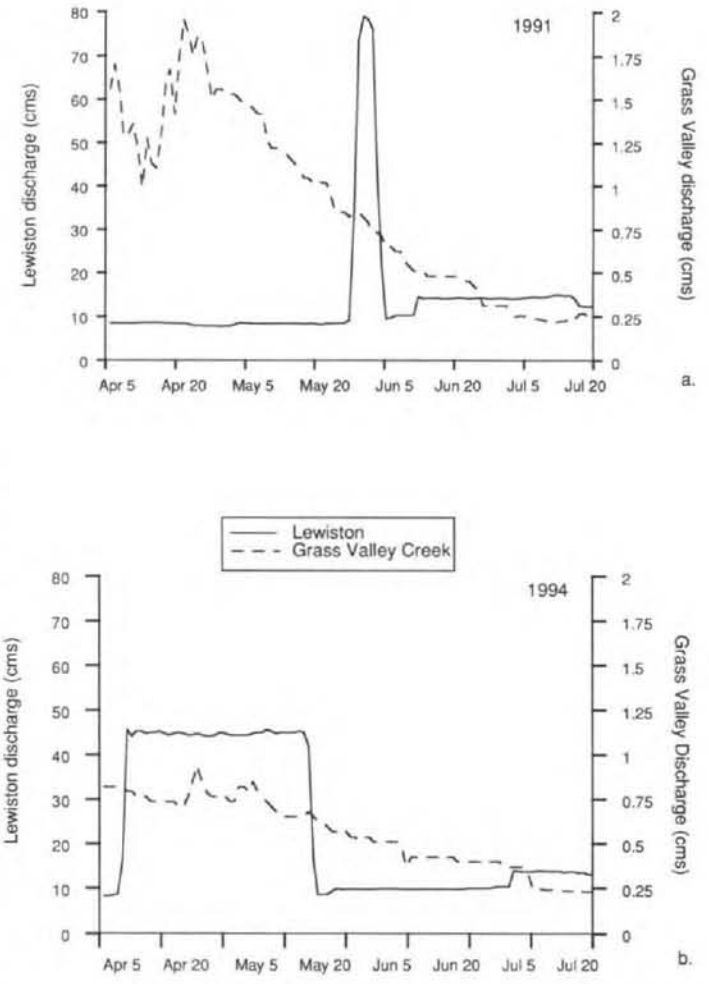

FIG. 3. Discharge (in cubic meters per second [cms]) hydrographs for the main stem Trinity River at Lewiston, and Grass Valley Creek, a tributary to the main stem below Trinity and Lewiston dams for (a) 1991 and (b) 1994.

Bullfrogs (*Rana catesbeiana*), a suspected predator on many native western ranids (Hayes and Jennings 1986; Moyle 1973), are present in the main stem Trinity (pers. obs.). Controlled flows and lack of winter flooding may actually increase suitable habitat for this exotic frog by providing stable pool areas with established aquatic vegetation. Changes in macro-invertebrate prey composition and abundance have been documented in many dammed river systems (Petts 1984) and these changes may affect native amphibians.

We believe the negative impacts we have identified on the main stem Trinity River can be reduced with thoughtful management. Habitat loss is a critical problem and *Rana boylii* has responded to "bank feathering" restoration projects within one year of construction. Ten of the 24 egg masses found in 1994 surveys were at restoration sites. However, we do not know whether frogs using these newly created habitats are additions to the breeding population or whether the frogs have moved into these areas simply because they are more suitable than what is currently available on the river.

Timing of high flows is more difficult to address because we do not know what environmental or other cues frogs use to ini-

tiate breeding. The timing of amphibian breeding is thought to be influenced by factors such as temperature and day length, which directly affect hormonal cycles (see Duellman and Trueb 1986 for a review). Metter (1961) speculated that for western toads (*Bufo boreas boreas*) breeding in riverine systems, timing and volume of run-off may also influence timing and location of breeding. An Asian stream-breeding frog, *Buergeria buergeri*, is known to decrease its breeding activity during heavy rainfall and high stream flows (Fukuyama and Kusano 1992). On the main stem Trinity, releases usually have been timed to mimic *average* predam patterns of spring run-off events. Using average conditions to determine flow schedules may or may not be consistent with environmental conditions in a given year. For example, if a threshold temperature or water level is required before frogs can initiate breeding and these conditions occur in April because of local climatic shifts, frogs may initiate breeding. If high-flow releases then occur in May of that year, egg masses or larvae are likely to be lost. Compare the discharge from an undammed tributary within the watershed to controlled discharges from Lewiston dam for the same time period in 1991 and 1994 in Figure 3. The tributary stream reflects the natural environmental conditions. In 1991 (and 1992, not shown), high flow releases from the dam occurred much later than the natural flow regime demonstrated by the tributary and in 1994 timing was similar between the main stem and the tributary. Note that 1994 was the only year in which we believe that a substantial portion of larvae survived to metamorphosis. A more appropriate strategy for *Rana boylii* and, we suspect, for most species that have evolved in stochastically fluctuating riverine environments, would be to base real-time changes in flow releases on current environmental conditions (e.g., if it is raining, release more water). Understanding the interactions between environmental factors (both natural and artificial) and frog breeding ecology is critical for managing water releases to reduce impacts on frogs and other species existing in dammed river systems.

Acknowledgments.—We thank G. Hodgson, M. Kamprath, and S. Mook for help with field work. D. Reese, L. Reid, and C. Zabel and two anonymous reviewers provided helpful comments on this manuscript. The Museum of Vertebrate Zoology at the University of California at Berkeley provided locality records for relevant counties (database printout dated 13 March 1995). The USDI Geological Survey provided discharge records for October 1990 through September 1994 for the Trinity River at Lewiston (Trinity County), California, station number 11525500, and Grass Valley Creek (Trinity County), California, station number 11525600.

Prey of the Introduced *Bufo marinus* on American Samoa

GILBERT S. GRANT
Department of Marine and Wildlife Resources
P.O. Box 3730, Pago Pago, American Samoa 96799, USA

Present address: Department of Biological Sciences,
University of North Carolina, Wilmington, North Carolina 28403, USA
e-mail: grantg@uncwil.edu

The giant cane or marine toad, *Bufo marinus*, is native to Central and northern South America (Zug and Zug 1979) but has been widely introduced to islands in the West Indies, the Pacific, Australia, and New Guinea (reviewed by Zug et al. 1975). In many areas it was introduced primarily to control sugar cane insect pests and has apparently been fairly successful in some areas in reducing damage to this crop (Wolcott 1937).

Bufo marinus was introduced from Hawaii to Tutuila Island (14°20'S, 170°43'W), American Samoa, in 1953 and the population was estimated to be over 2 million by 1976 (Amerson et al. 1982). Toads occur island-wide on Tutuila, have colonized neighboring Aunu'u Island, but do not presently occur on the nearby islands of Tau, Ofu, and Olosega, nor on Savaii and Upolu of Western Samoa.

Marine toads have catholic tastes (Alexander 1965; Hinckley 1963; McCoid 1994; Zug et al. 1975). The purpose of this study was to examine the food habits of marine toads in two different habitats on Tutuila, American Samoa.

On Tutuila Island, 26 toads were collected in suburban and park areas in the village of Tafuna and 28 were collected in secondary forest and primary rainforest (forest) of Amalau and Olovalu Crater near Futiga. Toads were collected from 24 October 1992 to 13 July 1994 and always 2–4 h after sunset to allow some time for foraging by the toads. Collected toads were immediately placed in plastic bags and frozen until processing.

Table 1. Mean (standard deviation) snout-vent lengths (SVL), jaw width (JW), and body mass minus stomach contents (BM) for 54 *Bufo marinus* in two habitats on Tutuila, American Samoa. Probabilities based on unpaired t- test.

	Combined N = 54	Suburban/Park N = 26	Forest N = 28	P
SVL (mm)	97.2 (13.9)	88.5 (11.9)	105.4 (10.2)	0.000
JW (mm)	36.9 (5.5)	33.8 (4.9)	39.8 (4.3)	0.000
BM (g)	90.6 (41.8)	68.0 (29.9)	111.6 (37.0)	0.000

Table 2. Mean (standard deviation) weight of entire contents, animal contents, and plant/grit contents from stomachs of *Bufo marinus* from two habitats on Tutuila, American Samoa. Probabilities based on t- tests.

	Suburban/Park N = 26	Forest N = 28	P
Entire contents (g)	2.3 (1.8)	4.7 (3.2)	0.001
Animal contents (g)	1.3 (1.7)	2.9 (2.1)	0.004
Plant/grit contents (g)	1.0 (1.2)	1.8 (1.9)	0.058

Intact toads, entire stomach contents, animal content of stomachs, and plant/grit content of stomachs were weighed to the nearest 0.1 g on a triple-beam balance. Snout-vent length (SVL) and maximum width of the jaws was measured with dial calipers to the nearest 0.1 mm. Animal prey were identified to the lowest possible taxonomic level and quantified.

Forest toads were longer, had wider gapes, and weighed more than suburban/park toads (Table 1). In addition, the stomachs of forest toads contained twice as much food by mass as did those of suburban/park toads. Animal contents, but not plant/grit contents, of the stomachs were significantly greater in forest toads (Table 2).

Toads in both habitat types took a wide variety of prey (Table 3). Nearly one half of the prey taken by forest toads was millipedes, whereas suburban/park toads took more moths, caterpillars, and beetles. The largest centipede taken was 51 mm long. Termites, geckos, and dog food were also eaten by toads in suburban/park habitats (P. Craig, B. Grant, P. Trail, pers. comm.), but the latter two items were not found in the stomachs of this study. Nearly equal numbers of animal prey were found in suburban/park toads (227) as in forest toads (217). Because the animal con-

tents in stomachs weighed twice as much in forest toads, individual prey items taken were substantially larger, on average. Toads took substantial quantities of plant material. Eighteen (69.2%) of suburban/park toad stomachs and 20 (71.4%) of forest toad stomachs contained plant material. Many very small arthropods were found among the vegetation in some toad stomachs. Two pieces of plastic wrap measuring 4 cm x 2 cm and 3 cm x 2 cm were found in one forest toad.

Zug et al. (1975) reported that *B. marinus* in rainforest habitats of New Guinea were both longer and heavier than savannah toads, a finding similar to that reported here. The body size differences reported in savannah and rainforest toads was attributed to the greater quantity and quality of food taken by rainforest toads (Zug et al. 1975). The size differences observed in American Samoan toads may be attributed to prey quality and quantity, sex ratio differences in the populations, or increased mortality rates in the suburban/park population. Unfortunately, I did not sex toads collected in this study. Zug and Zug (1979) showed that in neotropical populations females attained larger body size than males and that sex ratios varied in different populations. Some populations had twice as many males as females; others had twice as many females as males. Increased mortality rates were likely in the Samoan suburban/park habitat due to the presence of street lights and roads. Surface water for breeding was available in both Samoan habitats. Thus, the size differences are probably not due to differential recruitment rates.

Samoan forest toads consumed twice the quantity and animal content as did the suburban/park toads. Prey diversity was much greater in New Guinea toads (Zug et al. 1975) than Samoan toads, probably due to decreased prey diversity on small, distant islands. *Bufo marinus* is known to consume a wide variety of prey, including geckos, other toads, arthropods, vegetable matter, dog and cat food, and discarded pork spare ribs (Alexander 1965; Hinckley 1963; McCoid 1994; Zug et al. 1975; this study).

Many small arthropods (especially beetles and true bugs, Table 3) were found among some of the plant material in toad stomachs. Perhaps these arthropods were taken incidental to feeding on plant material, or conversely, the taking of plant material was

* includes 2 *Ostodes strigatus* and 20 *Subulina octona*.
** includes a fish scale 12 mm long and the tibia of *Rattus* sp.

incidental to the taking of small arthropods. The presence of a *Rattus* sp. tibia and a fish scale in toad stomachs is probably best attributed to incidental take while feeding on arthropods associated with carrion. Prey taken by neotropical populations of toads varied from one locality to the next and probably reflects the seasonal and habitat abundance of prey (Zug and Zug 1979).

Zug et al. (1975) reported toad densities 10 times greater in savannah habitats. I made no attempt to quantify densities. However, on Tutuila, American Samoa, population densities of *B. marinus* are highest in lowland areas with mowed lawns and villages and lowest in upland villages and forests (Amerson et al. 1982).

Acknowledgments.—This paper benefited from reviews by P. Craig, M. J. McCoid, W. Meshaka, J. F. Parnell, and M. Shields. This study was funded by the Federal Aid in Wildlife Restoration Act administered by the U.S. Fish and Wildlife Service.

The three most recent checklists concerning species composition of the Pacific islands of Baja California have reported *Uta stellata* and *Cnemidophorus tigris* as occurring on Isla San Benito (Bostic 1975; Grismer 1993; Wilcox 1980) although prior lists (Savage 1967; Van Denburgh 1905; Van Denburgh and Slevin 1914; Zweifel 1958) do not include these species. Despite the reports of Bostic (1975), Wilcox (1980) and Grismer (1993), no museum specimens from Isla San Benito exist.

Isla San Benito is a remote archipelago of three small islands totaling 6.6 km^2 in area and lying 31 km due west of Isla de Cedros. Along with Islas Natividad and Cedros, Isla San Benito comprises the westernmost extension of the Vizcaíno Peninsula off the west coast of central Baja California (see Grismer et al. 1994 for a map). On 10–14 July 1995, we and four others visited these islands to collect *Uta* and record field body temperatures of *Cnemidophorus tigris*. We visited all three islands of Isla San Benito on 11 July, searching for seven hours between 0900 and 1600. During this period, we observed hundreds of *U. stellata* but no *C. tigris*. Air and substrate temperatures ranged from 18.5°C and 39.2°C, respectively, at 1100 h to 28.3°C and 48.0°C, respectively, at 1500 h under sunny skies. We believe that these temperatures and weather conditions were well within the parameters at which *C. tigris* should have been active in this part of its range. This is based on the fact that we found *C. tigris* active on sunny days on Isla de Cedros on 10 and 12–13 July 1995 at air temperatures of 23.9–30.0°C and substrate temperatures of 34.0–43.6°C. Two lizards collected from Isla de Cedros during this period had body temperatures of 37.7°C and 39.9°C. Additionally, on 14 July, we found *C. tigris* abundant during an overcast day on Isla Natividad from 0925 to 1500 h. During this period, air temperatures ranged from 21.5–24.4°C and substrate temperatures ranged from 28.9–33.0°C. These temperatures were well below the highest ambient temperatures reported three days earlier from Isla San Benito yet on Isla Natividad, *C. tigris* were active and had body temperatures ranging from 28.9–31.9°C (N = 4). We believe this is strong evidence indicating that if *C. tigris* were present on Isla San Benito, it would have been active and observed. Additional negative evidence comes from the fact that there are no specimens of *C. tigris* from Isla San Benito catalogued in any of the museums we checked (CAS, CM, LACM, MVZ, SDSNH, USNM; museum acronyms follow Leviton et al. 1985; these museums were consulted because they have a history of receiving material from this portion of México) although there were a total of 434 specimens of *Uta stellata* from CAS, LACM, SDSNH, and USNM. It seems logical that during the collection of 434 *U. stellata* from these three small islands over the last 90 years at least one specimen of *C. tigris* would have been collected if the species were present.

The first report of *Cnemidophorus tigris* from Isla San Benito comes from Bostic (1975). This was presented in an unfinished guide to the natural history of north central Baja California and the adjacent islands that was poorly circulated due to Bostic's death while the book was in galleys. In it he stated that the only two species of reptiles "recorded" from Isla San Benito are *Uta stellata* and *C. tigris*. He went on to give a general description of how living lizards in the field can be distinguished by their respective behaviors but never actually states having seen *C. tigris*. Wilcox (1980), apparently having never visited the island, followed Bostic's (1975) report as did Grismer (1993), who followed both Bostic (1975) and Wilcox (1980). This report should serve as a caution to others compiling area checklists in that all taxa should be confirmed with either an institutional specimen or verified institutional photograph.

Acknowledgments.—We thank E. Gergus, C. Mattison, E. Mellink, and H. Wong for field assistance. Research was conducted under a scientific research permit (no. 05621) issued to E. Mellink by the Secretaria de Desarrollo Social and funded by a College of Arts and Sciences Grant from La Sierra University to LLG.

Additional Evidence for Rotenone Hazards to Turtles and Amphibians

MICHAEL JAMES MCCOID
Caesar Kleberg Wildlife Research Institute, Campus Box 218
Texas A&M University, Kingsville, Texas 78363, USA

and

PHILLIP W. BETTOLI
Tennessee Cooperative Fishery Research Unit
Tennessee Technological University, Box 5114
Cookeville, Tennessee 38505, USA

Rotenone, a biodegradable piscicide, is commonly used in fisheries management to sample, eradicate, or alter populations of fishes. A recent article (Fontenot et al. 1994) reviewed the known hazards of rotenone to aquatic reptiles and amphibians and suggested that impacts on these non-target organisms have been poorly documented. We herein present information on two separate instances where rotenone has impacted components of a herpetofauna.

As pointed out by Fontenot et al. (1994), larval amphibians may be particularly susceptible to rotenone treatment. In early 1974, African clawed frogs (*Xenopus laevis*) were discovered in a series of ponds in the upper Santa Clara River drainage, northern Los Angeles Co., California, USA. Efforts, including chemical eradication, were undertaken in spring 1974 to eliminate this perceived threat to nearby populations of the federally endangered unarmored three-spine stickleback (*Gasterosteus aculeatus williamsoni*) (St. Amant 1975). Several of these ponds were treated with "various chemicals at extremely high concentrations" (St. Amant 1975) with the result being the extirpation of *X. laevis* tadpoles. Adult *X. laevis* were unaffected, emigrated from the ponds, recolonized, and reproduced again later that spring. Although St. Amant (1975) did not specify the chemical agent(s) or the concentrations used in the abortive eradication procedure, a subsequent study (Zacuto 1975) identified the chemical as rotenone. Zacuto (1975) recognized the treated ponds as breeding areas for native amphibians (*Pseudacris regilla* and *Bufo boreas*) and while rotenone-targeted *X. laevis* was temporarily eliminated, it is also likely that sympatric tadpoles of native amphibians were also locally extirpated.

Hazards to freshwater turtles are less well documented than hazards to amphibians. Fontenot et al. (1994) speculated that turtles using buccopharyngeal, cloacal, or dermal aquatic respiration might be more susceptible to rotenone poisoning than those species that do not. At least some kinosternids and trionychids (see references in Fontenot et al. 1994) secondarily employ these respiratory mechanisms. A study, conducted between 1980 and 1986, used rotenone applications to partially assess fish community changes in a reservoir following aquatic vegetation removal (Bettoli et al. 1993). The 8100 ha reservoir (Lake Conroe, Montgomery Co., Texas, USA) was eutrophic, shallow (maximum depth 23 m), and harbored populations of turtles, including *Kinosternon subrubrum*. During the last two weeks of May of each year, six coves (total surface area 6.7 ha) were isolated with block nets and treated with rotenone (3 mg/L of 5% active ingredient, tradename Noxfish). During the first and second day of the standard three-day pickup period for fishes following treatment at each cove, it was noticed that dead or dying *K. subrubrum* were occasionally seen. At three of the six coves (maximum depths 2.4–5.5 m) during 1980–1981, we estimated that 10+ dead or dying *K. subrubrum* were observed around the periphery of each cove (60+ total). Dead turtles were seen on the bottom in water < 1 m

depth or lying on the bank. No information on turtles was recorded at the remaining three coves. Water visibility in the coves was reduced because outboard motors and airboats disturbed bottom sediments while thoroughly mixing rotenone in the water column. No other dead species of turtles or amphibians were recorded during 1980–1981. Estimated tallies for dead turtles from 1982–1986 were not recorded.

Although it appears that rotenone killed *K. subrubrum* in Lake Conroe, we have no way to estimate the impact on the local populations. Pre-treatment population densities are unknown, recolonization rates from adjacent untreated areas are unknown, and because *K. subrubrum* tends to sink when dead (pers. obs.) and are obscured by turbidity in deeper waters, total mortality cannot be estimated. Additionally, effects of rotenone may be enhanced in peripheral, shallower sections of treated areas, perhaps resulting in higher mortality rates. Rotenone treatments applied along shorelines may circumscribe escape routes for aquatic organisms and treatment levels of rotenone in shallow water will result in initially higher rotenone concentrations. If calculations for rotenone applications are based on the total volume of water to be treated, then, because of application techniques (aerial and/or subsurface), organisms will die sooner in shallow vs. deeper waters (pers. obs.).

It is clear that some non-target species are unintentionally vulnerable to rotenone treatments. Resolution of this problem, as suggested by Fontenot et al. (1994), may lie in a better understanding of the distributions and habitat uses of non-target species, their susceptibility to rotenone, and a more judicious application of toxicants such as rotenone.

Acknowledgments.—We thank Richard Noble (North Carolina State University) for facilitating this paper and Lance Fontenot for encouragement. A review of this paper was kindly done by Rebecca Hensley.

TECHNIQUES

A Harmless Technique for Sexing Hatchling Lizards

PETER S. HARLOW
School of Biological Sciences, AO8
The University of Sydney, 2006, NSW Australia

Both genotypic and temperature-dependent sex determination are known to occur in the agamid lizards (Viets et al. 1994). During a survey of sex determining mechanisms in the Australian Agamidae it became necessary to devise a harmless technique for sexing the hatchlings. Probing, and various techniques for everting the hemipenes, were tried and a simple, harmless and accurate technique was devised.

The recently hatched lizard is restrained either by cooling briefly in a refrigerator, or with the assistance of a second person, and laid belly-up (head to the left) under a low power (6–10X) dissecting microscope. The shaft of one dissecting needle is firmly held anterior and parallel to the cloaca, and a second is held at an angle of about 20–30° and used to gently evert the left hemipene by a forward rolling pressure on the lizard's left lateral tail base. For a 50 mm SVL hatchling this pressure should begin about 8 mm posterior to the cloaca, and for a 23 mm hatchling about 4 mm. In females, the cloaca will gape and a tiny gland-like structure may be seen on each side; in males, the left hemipene will be easily everted. The hemipene is bilobed, and much larger then the female structures. Although hemipene size varied slightly among male clutch mates, all lizards sexed were in one of these two categories; no intermediates were ever seen (Fig 1.).

I have used this technique to sex 715 hatchling agamids (ranging from 0.4 g to 5 g in mass) from 12 species in eight genera. Representatives of each species have been preserved for museum specimens and, upon dissection, hatchlings with hemipenes had ellipsoid gonads and no oviducts, whilst lizards without hemipenes had more disk-like, flattened gonads and clear oviducts. However, morphological differences were sometimes ambiguous so histology on 37 hatchlings was used to verified sex. Laparoscopy of 17 lizards and dissection of a further 72 individually marked lizards between 4 months and 2 years of age were also used to verify my original sex diagnosis. Females develop visible ovarian follicles after about 4 months of age in one species (*Physignathus lesueurii*); these and the oviduct are clearly seen on dissection or by laparoscopy. Testes from similar aged animals are "sausage-like" ellipsoids, and no oviducts are visible.

Among 126 agamids sexed as live hatchlings by the above technique that also had their gender subsequently verified by histology, laparoscopy, or by dissection over the three years of this study, only three (2.4%) were misdiagnosed. Two males were wrongly diagnosed as females, and one female was wrongly identified as a male. This last record was probably a data-recording error as the lizard had no evidence of hemipenes on later dissection. These three misdiagnosed specimens were from the first year of the study, and the male misdiagnosis probably resulted from not applying enough pressure to the tail base. It is important to have both males and females available when first attempting this technique. With experience, most hatchlings could be sexed correctly by visual comparison of the relative width of the tail base; in males it is slightly wider than in sibling females.

When 38 male *P. lesueurii* initially sexed at hatching were again sexed using this technique at three months of age, I could evert hemipenes in only 28 lizards (74%), and then only with difficulty. Subsequent dissection and verification by histology revealed no change of gender, but only my inability to evert the hemipenes in older animals. After death, the hemipenes were easily everted by injection of preservative into the tail 15 mm from the cloaca. This increasing difficulty to evert hemipenes with increasing age has also been reported in varanids (Hairston and Burchfield 1992) and pythons (Barker and Barker 1994) and is presumably due to increasing musculature in the tail.

With experience, this simple technique takes only a few seconds for each lizard and is completely harmless. A low power microscope is necessary only for the smaller species, but the extra magnification available allows only slight pressure to be applied to the tail base before the hemipene is easily seen without being fully everted. This technique may well work in other lizard families without tail autotomy (Chamaeleontidae, Iguanidae, Varanidae, etc.), and the accumulated data from many species may help explain the puzzling dichotomy of sex determining mechanisms within the lizards.

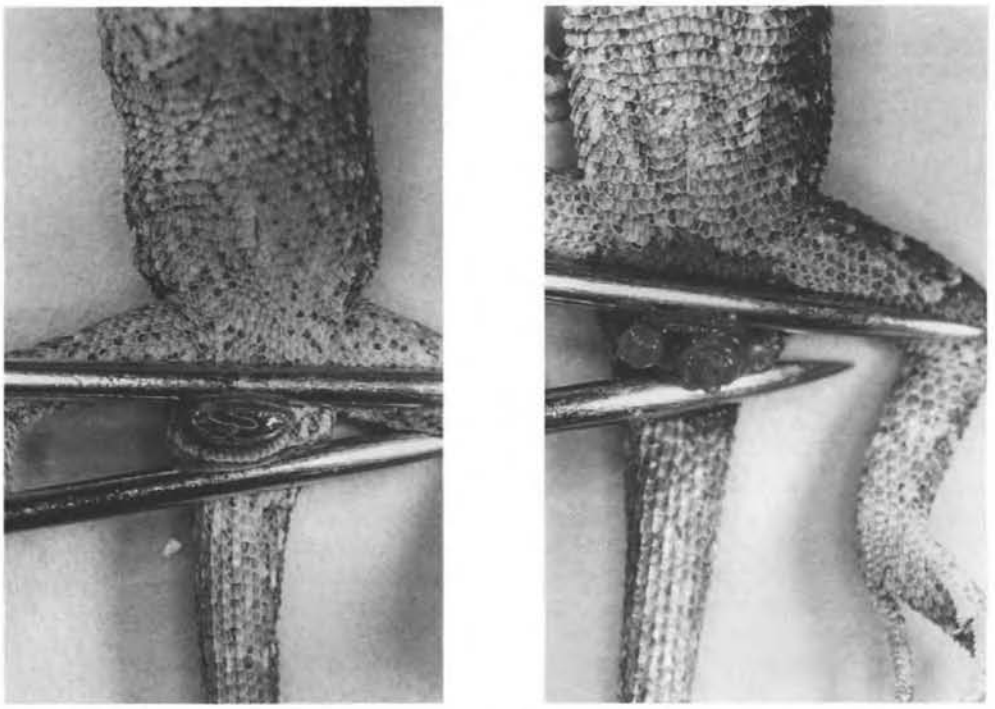

FIG. 1. Sexing hatchlings of the agamid lizard *Amphibolurus nobbi*. These lizards are 0.5 g and 26 mm SVL. (A) female, (B) male showing everted left hemipene and partially everted right hemipene.

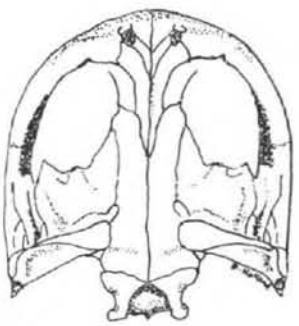

Acknowledgments.—I thank J. Stewart for teaching me the art of interpreting gonad histology, M. Ricketts for photography, and R. Shine for comments on the manuscript.

A Non-Flushing Stomach Wash Technique for Large Lizards

JESÚS ANTONIO RIVAS[1]
CESAR RAMÓN MOLINA[2]
and
TITO MANUEL ÁVILA[2]
Universidad Central de Venezuela, Instituto de Zoología Trópical, Caracas, Venezuela
Present addresses: [1] Department of Ecology and Evolutionary Biology, University of Tennessee, Knoxville, Tennessee 37996-0900, USA; and [2] Fundación Museo de Ciencias, Centro de Apoyo Adolfo Ernts, Calle El Comercio, Las Acacias, Venezuela

Stomach flushing has been proved useful in the study of lizard diets, but techniques have varied from one study to another (Henle 1989a; James 1990; Legler and Sullivan 1979; Shine 1986). We carried out a study of food habits in green iguanas (*Iguana iguana*) at Hato Masaguaral (a cattle ranch), Guárico, Venezuela (8°34'N, 67°35'W), and present the technique we used to recover stomach contents without killing or injuring the animals.

An iguana's mouth may be opened by gently pulling down the lower jaw, and then kept open by insertion of a metal ring (25 mm diameter, covered with several layers of masking tape to avoid damage to the teeth). Clear plastic tubes (8–15 mm diameter, depending upon animal size), with ends sanded to avoid cutting the stomach wall, may then be lubricated with vegetable oil and, while holding the animal's head in a vertical position, gently introduced through the ring into the throat. The tube is inserted past the initial resistance of the throat and until further resistance is met (a distance of about 60% snout-vent length), and then the tube is slowly backed out a distance of 1–2 cm, depending upon the size of the animal. The tube is then filled with water until the water level rises above the height of the mouth. The water in the tube is

then mixed with the stomach contents by gently massaging the belly; contents are removed by inverting the animal, retracting the tube an additional 2–3 cm (estimated distance from the hind wall of the stomach to the distal end of the sternum), and applying gentle pressure from the rear to the front of the stomach. The stomach contents are then collected in a plastic container; food becoming lodged in the mouth or pharynx is easily removed with forceps. This procedure is repeated 3–6 times for each animal and is stopped when the expelled water contains no plant items.

To test the efficiency of this procedure, one yearling and 13 hatchling iguanas were sacrificed, and the remaining stomach contents were analyzed after the procedure had been used. An average of 83.2%of all stomach contents (range 32–100 %) was recovered, and all species present in the stomach were detected in 13 of 14 cases. We did not consider it necessary to sacrifice larger animals to test the efficiency of the method.

Using this technique, we have been able to recover remains of 125 species of plants (Molina 1991; Rivas 1990). Stomach washing was performed on 365 iguanas ranging in size from hatchling (70 mm SVL, 12 g) to adult (up to 450 mm SVL, 4500 g). No animals died during the treatment although, in early attempts, some animals appeared weak after the maneuver. Many iguanas previously "stomach-washed" were recaptured in subsequent years and showed no ill effects.

This method provides a safe and easy way to study the dietary habits of large lizards. Because water is poured into the tube, no water pressure is applied to the animal gut, and no pump or syringe is needed. Although we used this method only for green iguanas, we believe it could be used with other lizards of comparable size; it was also used successfully with hatchling spectacled caiman (*Caiman crocodilus*) (Escalona, pers. comm.).

Acknowledgments.—We thank Thomás Blohm for the use of his ranch facilities, and the Wildlife Conservation Society (WCS) for financial support. Carlos Coronel allowed us to sacrifice some iguanas at his ranch. Gustavo Hernandez provided useful comments on the application of the technique. P. T. Andreadis, G. M. Burghardt, D. Truett, A. S. Rand, J. Thorbjarnarson, and A. E. Echternacht also provided useful comments and editorial suggestions.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send three copies of manuscripts, double-spaced, directly to the appropriate section coeditor (addresses on inside front cover): Lee A. Fitzgerald (lizards, amphisbaenians, crocodilians, Sphenodontia); Charles W. Painter (amphibians); or Paul A. Stone (snakes, turtles). Authors are encouraged to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a text-only version of the file.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins (1990. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 3rd ed., Herp. Circ. 19:1–41; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113). KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

ANURA

LITORIA FALLAX (Eastern Dwarf Treefrog). **REPRODUCTION.** McCoid (1993. Herpetol. Rev. 24:16–17) reported this introduced species as occurring island-wide on Guam, Mariana Islands, in association with wetlands. In the native range, neither Cogger (1988. Reptiles and Amphibians of Australia, 5th ed., Reed Books, Pty. Ltd., NSW, 688 pp.) nor Frith and Frith (1987. Australian Tropical Reptiles and Frogs, Tropical Australia Graphics, Queensland, 70 pp.) mentioned reproductive periodicity. Although calling males have been heard year-round on Guam after heavy showers, successful reproduction during the dry season (December–May) may be tied to episodic rainfall. Successful reproduction is probably seasonal in ephemeral bodies of water as tadpoles and froglets have only been observed during the rainy season. On Guam, many wetlands are ephemeral and tend to contract or disappear during the dry season.

Size at maturity is ca. 30 mm SVL and at metamorphosis, froglets are 11–13 mm SVL. At metamorphosis, froglets are brown dorsally, but turn green at they grow. Maximum known size on Guam is ca. 40 mm SVL.

Michael Ritter aided in field work and Rebecca Hensley reviewed a version of this manuscript. Portions of this study were supported by the Endangered Species Conservation Program, Project E4 (to Guam).

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19:1–41), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985(3):802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to the Section Co-editors, Joseph T. Collins (USA & Canadian records only), Natural History Museum—Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA, or Jerry D. Johnson (the rest of the world), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Painter, C. W., and C. M. Milensky. 1993. Geographic Distribution. *Crotalus tigris*. Herpetol. Rev. 24:155–156.

CAUDATA

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: GEORGIA: WALKER CO: Crockford-Pigeon Mountain Wildlife Management Area, ca. 50 m S jct. Atwood Point Road and McCutchens Spring Road, 625 m (2050 feet) elev. (34°41'35"N, 85°22'33"W). 2 September 1995. John B. Jensen. Verified by Raymond D. Semlitsch. UF Photograph 101002. New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Publ. 3:1–712) and probable range-wide maximum elevation record (R. Semlitsch, pers. comm.). Individual was found under a log within a drying sinkhole pond basin at the top of Pigeon Mountain.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). USA: VIRGINIA: ISLE OF WIGHT CO: 1.5 km NW Wills Corner, 20 m elev. 3 March 1992. K. A. Buhlmann. Several newly hatched larvae and 12 egg clusters were observed in a natural sinkhole pond. Two larvae were collected, preserved, and deposited in the Virginia Museum of Natural History (VMNH 6911). Verified by J. C. Mitchell, C. A. Pague, and R. L. Hoffman. One adult, sex unknown, was observed at the same pond on 2 February 1994 by C. S. Hobson. New county record; only the third confirmed breeding site in Virginia (Pague and Buhlmann 1991, Eastern Tiger Salamander, Virginia's Endangered Species. McDonald and Woodward Publ., Blacksburg).

Submitted by **KURT A. BUHLMANN**, University of Georgia, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA, and **CHRISTOPHER S. HOBSON**, Virginia Department of Conservation and Recreation, Division of Natural Heritage, 1500 East Main Street, Suite 312, Richmond, Virginia 23219, USA.

BOLITOGLOSSA PORRASORUM (NCN). HONDURAS: ATLÁNTIDA: S slope of Cerro Búfalo, Cordillera Nombre de Dios, 1580–1680 m elev. (15°39'N, 86°48'W). 16–18 February 1995. J. R. McCranie and J. C. Rindfleish. USNM 344784–88; ridge above Quebrada de Oro, Cordillera Nombre de Dios, 980 m elev. (15°38'N, 86°47'W). 13 February 1995. J. R. McCranie and J. C. Rindfleish. USNM 344783. All verified by L. D. Wilson. Extends range ca. 60 airline km NE of records from 2.5 airline km NNE La Fortuna, Departamento de Yoro, Honduras (McCranie and Wilson 1995, Herpetologica 51:131–140) and 0.8 km N and 1.5 km E Cerro San Francisco, Departamento de Atlántida, Honduras (Holm and Cruz D. 1994, Herpetologica 50:15–23, as *Bolitoglossa* sp.).

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157-2933, USA.

EURYCEA CIRRIGERA (Southern Two-lined Salamander). USA: OHIO: DARKE CO: Wayne Twp: unnamed tributary of the Stillwater River. 27 September 1995. W. J. Poly. Five juveniles and three adults (Southern Illinois University at Carbondale H-5049, H-5050, H-5051) were preserved; two other adults and several juveniles were also captured. Verified by R. A. Brandon. Stream is on the E side of the river and is bounded by Seibt, Kelch, Barnes, and St. Peters roads. It is depicted as intermittent on the USGS 7.5' Versailles, Ohio topographic map, but flows all year due to spring inflows and is intermittent only from near its origin at St. Peters Road to where it is nearest Kelch Road. Not recorded previously from Darke County (Pfingsten and Downs 1989, Ohio Biol. Surv. Bull. New Series Vol. 7(2) xx + 315 pp. + 29 pls.), although it has been recorded from the bordering counties of Shelby, Miami, Montgomery, and Preble. Abundance at this locality seems to have declined during the past 15 years (pers. obs.), possibly due, in part, to encroaching siltation and embedding of the substrate from upstream agricultural and bovine impacts. The lower half of the stream's length remains unaffected thus far. Janice and Gene Oliver allowed me to collect on their property.

Submitted by **WILLIAM J. POLY**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901-6501, USA.

NOTOTRITON BARBOURI (NCN). HONDURAS: ATLÁNTIDA: Ridge above Quebrada de Oro, Cordillera Nombre de Dios, 1210 m elev. (15°38'N, 86°47'W). 13 February 1995. J. R. McCranie and J. C. Rindfleish. Verified by L. D. Wilson. USNM 339712. New departmental record; extends range ca. 60 airline km NE of record from 2.5 airline km NNE La Fortuna, Departamento de Yoro, Honduras (McCranie and Wilson 1995, Herpetologica 51:131–140).

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157-2933, USA.

OEDIPINA GEPHYRA (NCN). HONDURAS: ATLÁNTIDA: S slope of Cerro Búfalo, Cordillera Nombre de Dios, 1580 m elev. (15°39'N, 86°48'W). 18 February 1995. J. R. McCranie and J. C. Rindfleish. Verified by L. D. Wilson. USNM 343462. Second known locality and new departmental record; extends range ca. 60 airline km NE of record from 2.5 airline km NNE La Fortuna, Departamento de Yoro, Honduras (McCranie et al. 1993, Proc. Biol. Soc. Washington 106:385–389).

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157-2933, USA.

PSEUDACRIS TRISERIATA MACULATA (Boreal Chorus Frog). USA: COLORADO: Kiowa Co: pond in ditch on W side of Co. Rd. 109, 0.1 mi. S jct. Co. Rd. T. 3 September 1995. Verified by Hobart M. Smith and David Chiszar. UNC-MNH 105 and UNC-MNC Photographs 1–2. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.).

Submitted by **STEPHEN P. MACKESSY, RON DONOHO, JUSTIN HOBERT, CHAD MONTGOMERY,** and **KEVIN WALDRON**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

RANA BLAIRI (Plains Leopard Frog). USA: TEXAS: Hockley Co: 5 km W Levelland. Summer 1973. Moore. TTUM 6655; near Levelland. July 1972. Moore. TTUM 6549–6550. All verified by Richard Monk. First county records (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **ANN M. ANDERSON** and **JAMES T. ANDERSON**, Department of Range, Wildlife and Fisheries Management, Texas Tech University, MS 2125, Lubbock, Texas 79409-2125, USA.

RANA CATESBEIANA (Bullfrog). USA: TEXAS: Garza Co: 14 km S Post. 14 April 1976. P. W. Sattler and T. Tandy. TTUM 8521. Verified by Richard Monk. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **ANN M. ANDERSON** and **JAMES T. ANDERSON**, Department of Range, Wildlife and Fisheries Management, Texas Tech University, MS 2125, Lubbock, Texas 79409-2125, USA.

RANA CATESBEIANA (Bullfrog). USA: TEXAS: Hardeman Co: Copper Breaks State Park, Pease River, 20.9 km S Quanah. 6 July 1990. J. R. Dixon. Verified by Kathryn Vaughan. Texas Cooperative Wildlife Collection (TCWC 67406, 67445). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA; and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA.

RANA CHALCONOTA (Coppercheek Frog). INDIA: GREAT NICOBAR: Galathea National Park. 11 March 1994. Centre for Herpetology, Madras Crocodile Bank Trust Collection (ID/AN 50–51); Shompen Hut. 17 March 1994. ZSI A8745–A8747; Kopen Heat. 19 March 1994. ID/AN 77 and 92. Indraneil Das and Satish Bhaskar. Verified by Anurup Sarkar and Shyamal Chanda. All examples were collected by hand from edges of ephemeral pools, where they were found perched on overhanging vegetation. New record for the Nicobars (see Sarkar 1990, Rec. Zool. Surv. India 86:103–117) and for the Republic of India (Dutta 1992, Hamadryad 17:1–13). Species is known from peninsular Thailand, the Malay Peninsula (including Singapore), Sumatra, the Mentawei Islands, Borneo, Java and Sulawesi (Inger 1966, Fieldiana Zool. n.s. 52:1–402; van Kampen 1923, The Amphibia of the Indo-Australian Archipelago. E. J. Brill, Leiden. xii + 304 pp.). White stripe below the eye extends to the edges of the upper labial, diagnostic of the subspecies *raniceps* (see Inger, *op cit.*). The new record, across the Great Channel from Achin Head in Sumatra, is an extension of range by ca. 180 km and is the westernmost record for the species.

Submitted by **INDRANEIL DAS**, Centre for Herpetology, Madras Crocodile Bank Trust, Post Bag 4, Mamallapuram 603 104, Tamil Nadu, India.

RANA SYLVATICA (Wood Frog). USA: WISCONSIN: Dane Co: Mazomanie State Wildlife Area, Sec. 32, T9N, R6E. 1 June 1995. P. B. Wolter. Verified by R. W. Hay. Milwaukee Public Museum (MPM 27950). New county record, documenting occurrence across the Wisconsin River from the nearest Sauk County record plotted by Vogt (1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., 205 pp.), although Mossman and Hine (1985, Wisconsin's Frog and Toad Survey-1984. Wisconsin Endangered Res. Rep. 16:1–16. Wisconsin Dept. Nat. Res., Madison) reported calling males in the same general vicinity.

Submitted by **PETER B. WOLTER**, Wisconsin Department of Natural Resources, Room 118, 1681 Second Avenue South, Wisconsin Rapids, Wisconsin 54495, USA, and **DREUX J. WATERMOLEN**, Wisconsin Department of Natural Resources, P. O. Box 7921, Madison, Wisconsin 53707-7921, USA.

SCINAX SQUALIROSTRIS (Stripesnout Treefrog). ARGENTINA: BUENOS AIRES: Partido de Mar Chiquita, Celpa (37°42'56"S, 57°23'15"W). 17 January 1994. P. Bellagamba and L. Vega. Verified by Jorge Williams. Herpetological Collection, Vertebrate Laboratory, Departamento de Biología, Universidad Nacional de Mar del Plata (UNMdP 0606–09). First county record (Cei 1980, Monitore Zool. Ital. (N.S.) Monogr. 2:609 pp). The four adults were collected from the axillae of the leaves of *Eryngium* sp. in a wet depression between coastal sand dunes; extends the range of this frog 220 km S from nearest known locality in Libres del Sur, Partido de Chascomús (Gallardo 1974, Anfibios de Ios Airededores de Buenos Aires. EUDEBA, Buenos Aires. 213 pp.).

Submitted by **LAURA E. VEGA** and **PATRICIO J. BELLAGAMBA**, Vertebrados, Departamento de Biología, Universidad Nacional de Mar del Plata, Funes 3350, 7600 Mar del Plata, Argentina

SPEA MULTIPLICATA (New Mexico Spadefoot). USA: TEXAS: Crosby Co: 14 km S Crosbyton. 14 April 1976. P. W. Sattler. TTUM 9410 and 9412. Verified by Richard Monk. Earliest date of first county record (Blair and Killebrew 1995, Herpetol. Rev. 26:154) and (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **ANN M. ANDERSON** and **JAMES T. ANDERSON**, Department of Range, Wildlife and Fisheries Management, Texas Tech University, MS 2125, Lubbock, Texas 79409-2125, USA.

TESTUDINES

APALONE MUTICA (Smooth Softshell). USA: OHIO: Clermont Co: Ohio Township, 2 mi N New Richmond, Pond Run Creek, 83 m from the Ohio River at Mile 452 (38°59'00"N, 84°17'30"W). 13 July 1995. Katherine A. McCafferty. Verified by John W. Ferner. Cincinnati Museum of Natural History (CMNH 4443). New county record (Zemko 1974, The Accuracy and Distribution of Turtles in Ohio. Master's Thesis, Miami University, Oxford, Ohio. 98 pp.).

Submitted by **KATHERINE A. McCAFFERTY** and **ADAM M. MANN**, Department of Biology, Thomas More College, 333 Thomas More Parkway, Crestview Hills, Kentucky 41017-3248, USA.

APALONE MUTICA MUTICA (Midland Smooth Softshell). USA: TEXAS: McCulloch Co: Colorado River and confluence with Salt Creek, 9.3 km ENE Doole. 13 September 1994. J. R. Smith and Chuck Brown. Verified by J. R. Dixon. Texas Cooperative Wildlife Collection (TCWC 71168). Brown Co: Colorado River, 2.4 mi ESE of Winchell on Crowder Ranch. 1030 h. 24 July 1995. Coll. J. R. Smith. Turtle found in riffle of river. Verified by J. R. Dixon. Texas Cooperative Wildlife Collection (TCWC 72199). New county records filling distributional gap between Concho and San Saba counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **J. R. SMITH, CHUCK BROWN,** and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: TEXAS: Hardeman Co: Copper Breaks State Park, Pease River, 20.9 km S Quanah. 6 July 1990. J. R. Dixon. Verified by Kathryn Vaughan. Texas Cooperative Wildlife Collection (TCWC 67194). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA; and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: TEXAS: Hardeman Co: Copper Breaks State Park, Pease River, 20.9 km S Quanah. 6 July 1990. J. R. Dixon. Verified by Kathryn Vaughan. Texas Cooperative Wildlife Collection (TCWC 67408). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA; and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). USA: TEXAS: Hardeman Co: Copper Breaks State Park, Pease River, 20.9 km S Quanah. 6 July 1990. J. R. Dixon. Verified by Kathryn Vaughan. Texas Cooperative Wildlife Collection (TCWC 67201). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA; and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA.

AMPHISBAENIA

AMPHISBAENA MERTENSII (NCN). ARGENTINA: CORRIENTES: Departamento Capital Corrientes: (23°28'S, 58°50'W). 13 March 1993. Blanca B. Alvarez. Colección Herpetológica Corrientes, Universidad Nacional del Nordeste, Corrientes, Argentina (CHC-UNNE 842); Departamento Saladas: San Lorenzo (28°08'S, 58°46'W). 15 October 1990. Pedro Galfrascoli (CHC-UNNE 4337); Departamento Santo Tomé: Gobernador Virasoro (28°03'S 56°01'W). 23 May 1991. Ramon Schneider (CHC-UNNE 538); CHACO: Departamento 1 de Mayo: Puerto Tirol (27°22'S, 59°05'W). 26 May 1990. Sara Bergna. (CHC-UNNE 4338, 4339); FORMOSA: Departamento Laishi: Presidente Irigoyen (26°10'S, 58°45'W). 11 September 1991. Sara Bergna (CHC-UNNE 573). All verified by R. Montero. New province records; extend range of species 400 km WNW of previous documented records (Cei 1993, Monogr. XIV, Mus. Reg. Sci. Nat. Torino:1–949; Montero 1994, Bol. Asoc. Herp. Argen. 10(1):43–46).

Submitted by **BLANCA BEATRIZ ALVAREZ**, Compared Anatomy Division, Biology Departament, Facultad de Ciencias Exactas y Naturales, Universidad Nacional del Nordeste, 9 de Julio 1449, 3400 Corrientes, Argentina.

AMPHISBAENA PRUNICOLOR PRUNICOLOR (NCN). ARGENTINA: CORRIENTES: Departamento San Martin: La Cruz (29°11'S, 56°40'W). 15 February 1994. L. Lions, J. Cespedez, and R. Aguirre. Verified by R. Montero. Colección Herpetológica Corrientes, Universidad Nacional del Nordeste, Corrientes, Argentina (CHC-UNNE 804–805). First province record; extends range 200 km SW of nearest records in Misiones Province, Argentina (Cei 1993, Monogr. XIV, Mus. Reg. Sci. Nat. Torino:1–949; Montero 1994, Bol. Asoc. Herp. Argen. 10(1):43–46).

Submitted by **BLANCA BEATRIZ ALVAREZ**, Compared Anatomy Division, Biology Departament, Facultad de Ciencias Exactas y Naturales, Universidad Nacional del Nordeste, 9 de Julio 1449, 3400 Corrientes, Argentina.

LACERTILIA

ANISOLEPIS LONGICAUDA (Longtail Lizard). PARAGUAY: DEPARTAMENTO ITAPUA: Isla Yacyreta (27°21'S, 56°20'W). 25 August 1994. M. L. Lions and R. Aguirre. Verified by J. M. Cei. Colección Herpetologica Corrientes, Universidad Nacional del Nordeste, Corrientes, Argentina (CHC-UNNE 878, 889, 891, 915, 918, 922, 1325–1329). First department record; southernmost record from Paraguay.

Submitted by **MARIA LUISA LIONS** and **BLANCA BEATRIZ ALVAREZ**, Compared Anatomy Division, Biology Departament, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de Julio 1449, 3400 Corrientes, Argentina.

EUMECES OBSOLETUS (Great Plains Skink). USA: COLORADO: LINCOLN CO: two neonates in pitfall on W side of Co. Rd. 43 ca. 2.1 mi S jct. Rt. 94; LINCOLN CO: young adult under rock on E bank Sandy Creek 100 m W of bridge on Co. Rd. 29, 2.2 mi S jct. Rt. 94. Both 9 September 1995. Both verified by Hobart M. Smith and David Chiszar. UNC-MNH Photographs 3–6. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.).

Submitted by **RON DONOHO, JUSTIN HOBERT, CHAD MONTGOMERY,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

HEMIDACTYLUS FRENATUS (House Gecko). USA: TEXAS: GALVESTON CO: Port of Galveston, Pier 19. 19 November 1988. Stephen F. Austin State University Vertebrate Museum (SFAVM 4885, juv. male). P. D. Klawinski and D. Saenz. Verified by James R. Dixon. This lizard was collected at about same location from which *Cyrtopodium scabrum* was first reported in the United States [Selcer and Bloom 1984, Southwest. Nat. 29(4):499–500]. We made approximately seven subsequent collecting trips to Pier 19 during 1989 and 1990 and did not find another *Hemidactylus frenatus* specimen; new county record and is one of the earliest catalogued records for the United States.

Submitted by **DANIEL SAENZ**, Wildlife Habitat and Silviculture Laboratory, Southern Research Station, USDA Forest Service, Nacogdoches, Texas 75962, USA (in cooperation with the College of Forestry, Stephen F. Austin State University, Nacogdoches, Texas 75962, USA), and **PAUL D. KLAWINSKI**, Department of Biology, University of Texas at Arlington, Arlington, Texas 67019, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: LOUISIANA: WEST FELICIANA PARISH: Francis Hotel On The Lake on U.S. Rt. 61 in St. Francisville, 30°47'7.6"N, 91°22'36.4"W. UMMZ 210737–738. 27 May 1995. ST. TAMMANY PARISH: abandoned drive-in theater between Slidell and Lacombe, N side U.S. Rt. 190, 30° 17' 57.2"N, 89° 48' 33.6"W. UMMZ 210780. 26 May 1995. Russell L. Burke, Daniel A. Erickson, Ashley T. Mattoon. Both verified by A. G. Kluge. West Feliciana Parish is a new parish record for this species; a large population was observed there. St. Tammany Parish locality is close by the town of Hickory, which is the previously reported site for that parish (Dundee and Rossman 1989, Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge. 300 pp.; H. A. Dundee, pers. comm.).

Submitted by **RUSSELL L. BURKE**, School of Natural Resources and Environment, University of Michigan, Ann Arbor, Michigan 48109-1115, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: CROCKETT CO: Ozona. 28 April 1991. J. R. Dixon. Verified by Kathryn Vaughan. Texas Cooperative Wildlife Collection (TCWC 69069); COLEMAN CO: O. H. Ivie Reservoir, Kennedy Recreation Park, Elm Creek Village, 13.7 km SW Voss. 12 September 1994. J. R. Smith. Specimen captured in trailer house. Verified by Kathryn Vaughan. Texas Cooperative Wildlife Collection (TCWC 71169). New county records representing significant range extensions for this introduced species (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **J. R. SMITH** and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA; and **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

LIOLAEMUS OLONGASTA (NCN). ARGENTINA: SAN JUAN: Zonda Department, 23 km W San Juan city (31°31'S, 68°26'W) on side slope and dry bed of De la Ciénaga River in Zonda Valley. December 1994. Fernando Murúa. Verified by Luciano Javier Avila. Herpetological collection of Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Argentina [IMCN-UNSJ 100 (male) and 101 (female)]; extends range ca. 40 km from population in the southern region of the Bolsón de Matagusanos, Jáchal Department, San Juan Province (Etheridge 1993, Boll. Mus. Reg. Sci. Nat. Torino, vol. 11, No. 1, pp. 137–199).

Submitted by **JUAN CARLOS ACOSTA, FERNANDO MURÚA** and **GRISEL ORTIZ**, Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Avenida Libertador (Oeste) No. 315, C. P. 5400, San Juan, Argentina.

LIOLAEMUS WIEGMANNI (NCN). PARAGUAY: ISLA YACYRETA: Cerro Ybycui (27°26'S, 56°24'W). 10 September 1994. Aguirre R. y. Cespedez J. Verified by J. M. Cei. Colección Herpetologica Corrientes, Universidad Nacional del Nordeste, Corrientes, Argentina (CHC-UNNE 890). First island record; extends range 150 km ENE from nearest record in Corrientes, Argentina (Tedesco et al. 1992, FACENA 9:117–122)

Submitted by **BLANCA BEATRIZ ALVAREZ** and **MARIA LUISA LIONS**, Compared Anatomy Division, Biology Departament, Facultad de Ciencias Exactas y Naturales, Universidad Nacional del Nordeste, 9 de Julio 1449, 3400 Corrientes, Argentina.

NOROPS PURPURGULARIS (Middle American Anole). HONDURAS: ATLÁNTIDA: S slope of Cerro Búfalo, Cordillera Nombre de Dios, 1630-1760 m elev. (15°39'N, 86°48'W). 15–17 February 1995. J. R. McCranie and J. C. Rindfleish. Verified by L. D. Wilson. USNM 344806-17. Extends range ca. 60 airline km NE of only previous records for the species from 2.5 airline km NNE La Fortuna, Departamento de Yoro, Honduras, and 0.4–1.0 km N and 0.1 km W–2.1 km E Cerro San Francisco, Departamento de Atlántida, Honduras (McCranie et al. 1993, J. Herpetol. 27:386–392).

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157-2933, USA.

PHYLLODACTYLUS XANTI (Cape Leaf-toed Gecko). MÉXICO: SONORA: Isla Dátil. 6 October 1995. L. Lee Grismer. Verified by Bradford D. Hollingsworth. LACM PC 1327. Adult

male found at 0915 h within rock crack at base of talus slope in northeastern-facing arroyo; first report of this species from Isla Dátil (Murphy and Ottley 1984, Ann. Carnegie Mus. 53:207–230). A hatchling was also found in the same locality, suggesting that this is a viable population and not a chance overwater dispersal from nearby Isla Tiburón.

Submitted by **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

SAUROMALUS ATER ATER (Espíritu Santo Chuckwalla). MÉXICO: BAJA CALIFORNIA SUR: Isla Ballena, an islet off the west coast of Isla Espíritu Santo. 27 July 1995. Bradford D. Hollingsworth and L. Lee Grismer. Verified by Chris Mattison. LACM-PC 1325. First record for Isla Ballena (Murphy and Ottley 1984. Ann. Carnegie Mus. 53:207–230). This specimen was photographed and released on site.

Submitted by **BRADFORD D. HOLLINGSWORTH**, Department of Natural Sciences, Loma Linda University, Loma Linda, California 92350, USA, and **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

SERPENTES

AGKISTRODON CONTORTRIX LATICINCTUS (Broad-banded Copperhead). USA: TEXAS: Mills Co: Rt. 84, 13.5 km E of Goldthwaite. 11 May 1991. J. R. Dixon. Specimen found DOR. Verified by Kathryn Vaughan. Texas Cooperative Wildlife Collection (TCWC 69070). New county record; fills hiatus in distribution (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA; and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA.

AGKISTRODON CONTORTRIX MOKASEN (Northern Copperhead). USA: INDIANA: Dearborn Co: Bright, ca. 0.1 km E jct. of Stateline and Jamison Roads. September 1992. Chris Griffith. Verified by John W. Ferner. Cincinnati Museum of Natural History (CMNH Color Slide HP023; KU Color Slides 11221–223). New county record (Minton 1972, Indiana Acad. Sci. Monogr. 3:1–346). Currently alive in captivity in the author's collection. Specimen to be deposited in the CMNH collection upon its death. Since September 1992, additional specimens have been reported from this locality by the collector.

Submitted by **PETER D. STRIMPLE**, Reptile Research and Breeding Facility, 5310 Sultana Drive, Cincinnati, Ohio 45238, USA.

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: TEXAS: Blanco Co: 7.2 km W & 0.8 km S jct. FM Rt. 3347 & FM Rt. 962 off FM Rt. 3347 on trib. to White's Creek. 8 October 1995. Cathy Arveson. Verified by James R. Dixon. TCWC 72204. Adult male. New county record; fills gap between Burnet, Llano, and Kendall counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **R. KATHRYN VAUGHAN** and **GEORGE D. BAUMGARDNER**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843-2258, USA.

ARIZONA ELEGANS ELEGANS (Kansas Glossy Snake). USA: COLORADO: Kiowa Co: DOR Rt. 287 at jct. Co. Rd. V. 21 June 1995. Verified by Hobart M. Smith and David Chiszar. UNC-MNH 101. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.).

Submitted by **JUSTIN HOBERT, RON DONOHO, CHAD MONTGOMERY, KEVIN WALDRON**, and **STEPHEN P. MACKESSY,** Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

ARIZONA ELEGANS ELEGANS (Kansas Glossy Snake). USA: COLORADO: Crowley Co: AOR Rt. 96 0.1 mi W jct. Co. Rd. 28. 23 September 1993. Verified by Hobart M. Smith and David Chiszar. UNC-MNH photographs 9–10. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.).

Submitted by **JUSTIN HOBERT, BRANDON QUINN, RON DONOHO, CHAD MONTGOMERY, KEVIN WALDRON** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer). USA: COLORADO: Crowley Co: DOR Co. Rd. 10, 8.6 mi N jct. Rt. 96. 21 July 1995. Verified by Hobart M. Smith and David Chiszar. UNC-MNH 103. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.).

Submitted by **JUSTIN HOBERT, RON DONOHO, CHAD MONTGOMERY, KEVIN WALDRON** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

DIADOPHIS PUNCTATUS ACRICUS (Key Ringneck Snake). USA: FLORIDA: Monroe Co: Lower Florida Keys, No Name Key, Key Deer National Wildlife Refuge, on unnamed sand road 0.2 km SSE of jct. with Old State Road 4A (North Watson Blvd), 1.6 km from W side of island and elevated concrete bridge connected to Big Pine Key. Photographed and released at 1930 h (Florida threatened subspecies), crossing road through a patch of tropical hardwood hammock surrounded by pineland. 19 September 1995. C. Scott. Verified by D. L. Auth. UF Color Slide 100941. New island record. Previously recorded from Big Pine Key and Middle and Little Torch Keys in the Lower Keys (Lazell 1989, Wildlife of the Florida Keys: A Natural History. Island Press, Washington, D.C. and Covelo, California. 250 pp).

Submitted by **DAVID L. AUTH** and **CHRIS SCOTT**, Division of Herpetology, Florida Museum of Natural History, Gainesville, Florida 32611, USA.

DIADOPHIS PUNCTATUS ARNYI (Prairie Ringneck Snake). USA: COLORADO: Bent Co: DOR Rt. 101, 0.1 mi S jct. Co. Rd. T. 7 July 1995. Verified by Hobart M. Smith and David Chiszar. UNC-MNH 102. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.).

Submitted by **CHAD MONTGOMERY, KEVIN WALDRON, JUSTIN HOBERT, RON DONOHO,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

ERIDIPHAS SLEVINI SLEVINI (Slevin's Night Snake). MÉXICO: BAJA CALIFORNIA SUR: Rancho La Presa: 108 km N La Paz. 16 July 1988. L. Lee Grismer. Verified by Bradford

D. Hollingsworth. LACM PC 1318. Found at 2100 h crawling on a graveled hillside; fills in a distribution gap through the Sierra de La Giganta of 237 km from La Paz to Loreto (Ottley and Tanner 1978, Great Basin Nat. 38:406–410).

Submitted by **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

GYALOPION CANUM (Western Hooknose Snake). USA: TEXAS: Coleman Co: Maintenance Shop, lab floor; 35.9 km S and 24.3 km W of Coleman. 5 July 1988. J. R. Dixon. Verified by Kathryn Vaughan. Texas Cooperative Wildlife Collection (TCWC 69134); CRMWD Stacy Dam Shop, 16.9 km SW of Voss. 3 July 1989. J. R. Smith. Specimen found in open at west end of shop. Verified by Kathryn Vaughan. TCWC 67527; CRMWD Maintenance Shop near O. H. Ivie Reservoir Dam, 16.9 km SW of Voss. 3 June 1995. D. J. Strengths and G. Laws. Specimen found under a rock. Verified by Kathryn Vaughan. TCWC 72195. Although catalogue locality entries vary somewhat, each specimen is from the same location; new county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **J. R. SMITH** and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA; and **JAMES R. DIXON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

IMANTODES CENCHOA (Blunt-headed Tree Snake, Dormideira). BRAZIL: SÃO PAULO: Peruibe: Estação Ecológica da Juréia-Itatins (24°25'S, 47°14'W). 16 November 1994. M. Messias. Verified by G. Puorto. Instituto Butantan (IB 55813). First record from Atlantic Forest of southeastern Brazil. Species is distributed from the Isthmus of Tehuantepec region of México through Central America and South America to Paraguay and Bolivia (Peters and Orejas-Miranda 1970, Bull. U.S. Nat. Mus. 297:133). In Brazil, this snake is found in western and northern sections (Amaral 1978, Serpentes do Brasil, Melhoramentos/ Universidade de São Paulo, 2 ed., São Paulo 246 pp.).

Submitted by **OTAVIO A. V. MARQUES**, Laboratório de Herpetologia, Instituto Butantan, Av. Vital Brasil, 1500, CEP 05503-900, São Paulo, SP, Brasil.

LAMPROPELTIS GETULA NIGRITA (Black Desert Kingsnake). MÉXICO: SONORA: Isla San Pedro Nolasco, ca. 16 km off adjacent coastline immediately N of Bahía de San Carlos. 7 October 1995. L. Lee Grismer. Verified by Bradford D. Hollingsworth. La Sierra University Herpetology Collection (LSUHC 1313). A complete freshly shed skin was found at 0830 h on the eastern face of the island, one-third of the way up to the crest; first record of a snake from Isla San Pedro Nolasco (Murphy and Ottley 1984, Ann. Carnegie Mus. 53:207–230). Specimen is identified here as the subspecies *L. g. nigrita* based on its absence of a dorsal pattern and the darkness of the shed. *Lampropeltis g. nigrita* from the adjacent mainland is also solid black (Blaney 1977, Tulane Stud. Zool. Bot. 19:47–103.

Submitted by **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

LAMPROPELTIS TRIANGULUM (Milk Snake). USA: TEXAS: Willacy Co: Lower Rio Grande Valley National Wildlife Refuge, 2.5 mi E jct. County Roads FM 498 and FM 1420, Willamar Tract. 18 July 1992. Kelly J. Irwin and Martin Bray. Verified by Joseph T. Collins (KU Color Slide 11224). County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp).

Submitted by **KELLY J. IRWIN**, Department of Wildlife & Fisheries Sciences, Texas A&M University, College Station, Texas 77843-2258, USA, and **SUZANNE L. COLLINS**, School of Education, University of Kansas, Lawrence, Kansas 66045, USA.

MASTICOPHIS LATERALIS LATERALIS (California Striped Racer). MÉXICO: BAJA CALIFORNIA SUR: Cañón de Los Reyes, 37 km north of La Paz. 16 October 1994. Clark R. Mahrdt and L. Lee Grismer. Verified by Robert L. Bezy. LACM PC 1319. Found at 2200 h crawling along the edge of a rocky arroyo; extends distribution southward ca. 225 km through the Sierra de La Giganta from Arroyo La Sanca, and brings species to within ca. 55 km of its close relative, *M. aurigulus* of the Cape Region (Grismer 1994, Herpetologica 46:66–77).

Submitted by **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, CA 92515-8247, USA and **CLARK R. MAHRDT**, Southwestern Biologists, 9847 Willow Lane, Escondido, California, 92092, USA.

MICRURUS CORALLINUS (Coral Snake). BRAZIL: Bahia: Municipio de Simões Fiho, Estação Ecológica de Cotegipe. 24 June 1994. D. F. Sampaio. UFBA/LAP 829. Rio Grande do Norte: Município de Nísia Floresta, EFLEX-IBAMA. 19 March 1992. C. E. Barreto. UFBA/LAP 828. Both verified by William Lamar. These are the first records of this species for NE Brazil; extend known range over 900 km N of closest published locality [Illhéus 1992, História Natural de *Micrurus corallinus* (Serpentes, Elapidae). 80 pp.].

Submitted by **LUCIANA LYRA CASAIS E SILVA**, Laboratório de Herpetologia, Instituto Butantan, Ave. Vital Brazil 1500, 05504-900, São Paulo, São Paulo, Brazil, and **TANIA BRAZIL NUNES**, Laboratório de Animail Peçonhentos, Departamento de Zoologia, Instituto de Biologia, UFBA, Campus Universitário de Ondina, 40170-210, Salvador, Bahia, Brazil.

MICRURUS LEMNISCATUS (Coral Snake). ARGENTINA: Provincia de Corrientes: Empedrado. 12 November 1993. L. Rey. Museu de Zoologia—Universidade de São Paulo (MZUSP 10813). Provincia de Misiones: Azara. 9 October 1967. Ministério de Assistencia Social. Museo Argentino de Ciencias Naturales (MACN 2403, ex-CENAI); Apostoles. 17 October 1969. MACN 3043; 23 May 1994. R. Repetto. MZUSP 10821. All verified by Jack W. Sites Jr. These are the first records of *Micrurus lemniscatus* for Argentina and they agree well with the description of *M. l. carvalhoi*. The closest localities are in the Brazilian state of Paraná and in northern Paraguay [Jorge da Silva 1995, Molecular Systematics and Evolution of Venom in the South American Triad (*Micrurus*) Coral Snakes. Ph.D. dissertation. 226 pp.]. The region of Corrientes and Missiones are located between the Rio Paraná and Rio Uruguay Basins. Elevations are between 100 and 500 m. In Argentina this form has been misidentified as *M. frontalis mesopotamicus*; they are sympatric in the Mesopotamia region (NJS, pers. obs.).

NERODIA HARTERI PAUCIMACULATA (Concho Water Snake). USA: TEXAS: MITCHELL CO: Spade Ranch, Pecan Crossing of Colorado River, 17.7 km NW of Silver. 14 June 1995. J. R. Smith and Chuck Brown. Verified by J. R. Dixon. Texas Cooperative Wildlife Collection (TCWC 72197). Specimen captured in minnow trap. River discharge ca. 80 CFS. New county record extending the range of this species approximately 24 km upstream of E. V. Spence Reservoir (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). Texas Permit No. SPR-0790-208.

Submitted by Submitted by **J. R. SMITH, CHUCK BROWN** and **OKLA W. THORNTON, JR.**, Colorado River Municipal Water District, Environmental Recreation Division, Ivie Reservoir Field Office, HCR 82, Box 4B, Leaday, Texas 76888, USA.

PHYLLORHYNCHUS DECURTATUS (Western Leafnose Snake). MÉXICO: BAJA CALIFORNIA: Bahía de San Luis Gonzaga. 30 July 1986. L. Lee Grismer. Verified by Bradford D. Hollingsworth. LACM PC 1321. Found at 2100 h crawling on the top of a boulder in Arroyo de Rumbaugh; extends range southward ca. 200 km from 80 km north of San Felipe (McCleary and McDiarmid 1993, Cat. Amer. Amph. Rept. 580). Specimen is a female with 25 subcaudals, 33 dorsal body blotches and six caudal blotches, all of which fall within the range of *P. d. perkinsi* and *P. d. decurtatus*. It also has 184 ventrals which is diagnostic of *P. d. perkinsi*. However, its dorsal blotches are as wide or wider than the interspaces, which is similar to *P. d. decurtatus*. It is believed that this specimen is an intergrade between these two subspecies and demonstrates the continuous distribution of this species throughout the Baja California peninsula.

Submitted by **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

PITUOPHIS MELANOLEUCUS ANNECTENS (San Diego Gopher Snake). MÉXICO: BAJA CALIFORNIA: Km Marker 97, 42 km south (on Mex. Rt. 1) of El Rosario. 5 October 1994. L. L. Grismer and C. R. Mahrdt. Verified by Robert L. Bezy. LACM 1301. Extends known range S by 18.5 km [Grismer 1994, Herpetol. Nat. Hist. 2(1):51–106]. Grismer (*op. cit.*) elevated *P. m. vertebralis* to species status (*P. vertebralis*) based on the discovery of the northernmost specimen (LACM PC 1266) 19.5 km S of the southernmost *P. melanoleucus* (LACM 1265) and the fact that these specimens exhibited no signs of intergradation. This new specimen (LACM PC 1301) closes that gap to 1 km, indicating that these two species are probably sympatric, supporting their recognition as separate species. Sweet and Parker (1990, Cat. Amer. Amph. Rept. 474.1–474.8) noted that *P. m. annectens* has 65–106 dark, dorsal blotches and *P. vertebralis* (=*P. m. bimaris*) north of the Isthmus of La Paz has 34–46. However, Klauber (1946, Trans. San Diego Soc. Nat. Hist. 11:1–40) noted that *P. m. annectens* from Baja California have 57–90 dorsal blotches and those from the United States have 56–102 (Klauber 1947, Bull. Zool. Soc. San Diego 22:1–83). LACM PC 1301 has 53 dorsal blotches which falls outside the range of both species but is close to that of *P. m. annectens*. It has other characteristics absent from *P. vertebralis* but present in *P. melanoleucus* such as the absence of a dark subcaudal stripe and large, light-colored, regular blotches on the nape enclosed in black. It should be noted that Grismer (*op. cit.*) mistakenly listed LACM PC 1265 and 1266 as occurring 68.5 km and 98 km S by road of El Rosario, respectively. Instead, the localities should have read Km Marker 68.5 and Km Marker 98 south (on Mex. Rt. 1) of El Rosario, which occurs at Km Marker 55, 55 km S of San Quintín.

Submitted by **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California, 92515-8247, USA, and **CLARK R. MAHRDT**, Southwestern Biologists, 9847 Willow Lane, Escondido, California 92092, USA.

PITUOPHIS RUTHVENI (Louisiana Pine Snake). USA: LOUISIANA: CALCASIEU PARISH: S of Lake Charles and E of jct. of Tank Farm Road and Elliot Road on Mackerel Drive. 2 September 1988. Avery A. Williams and Andy Boutilier. Seale Museum of Louisiana, McNeese State University (SML 9291); JEFFERSON DAVIS PARISH: ca. 6 mi NW Jennings. November 1966. Edward C. Bush. SML 1274. Both verified by James R. Dixon and are first records for respective parishes. Discovery of these specimens extends the Louisiana range southward (Dundee and Rossman 1989, Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge, 300 pp.). Prior to this report, Dundee and Rossman (*op. cit.*) cited the southernmost Louisiana distribution as Beauregard Parish based on literature records. With the addition of these two parish records, the distribution of this species in southwest Louisiana is extended and clarified.

RHINOCHEILUS LECONTEI TESSELLATUS (Texas Longnose Snake). USA: COLORADO: CHEYENNE CO: DOR Rt. 287 0.1 mi S jct. Co. Rd. C. 12 August 1995. Verified by Hobart M. Smith and David Chiszar. UNC-MNH 104. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.).

Submitted by **KEVIN WALDRON, CHAD MONTGOMERY, JUSTIN HOBERT, RON DONOHO,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

SISTRURUS CATENATUS (Massasauga). USA: COLORADO: El Paso Co: DOR Shear Rd., 0.8 mi W jct. Whittemore Rd. 22 May 1995. Verified by Hobart M. Smith and David Chiszar. UNC-MNH 100. Recent county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.). This species is threatened by habitat conversion and persecution in much of its range; the most recent previous record in El Paso County was in 1987 or 1988 as reported by Pegler et al. (1995. Herpetol. Rev. 26:47). This specimen indicates that the Massasauga still occurs in (at least) limited numbers in eastern El Paso County. As it has been extirpated from much of its range nationwide, this species is probably deserving of protected status in Colorado.

UNC museum records dating from 1882 indicated the presence of this species in Baca County, Colorado, as follows: USA: COLORADO: Baca Co: no further data. This specimen was collected by Mr. A. E. Beardsley in 1882 and entered as accession number 96-265 in the "Colorado State Normal College" Museum Register 3. This would represent a new county record and a considerable range extension to the south in Colorado (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.); unfortunately the specimen no longer exists in the UNC-MNH collection.

Submitted by **STEPHEN P. MACKESSY, JUSTIN HOBERT, RON DONOHO, CHAD MONTGOMERY,** and **KEVIN WALDRON**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

TANTILLA NIGRICEPS NIGRICEPS (Plains Blackhead Snake). USA: COLORADO: Kiowa Co: floating on board in water-filled cistern on E side of Co. Rd. 109, 0.5 mi N jct. Rt. 96. 16 September 1995. Verified by Hobart M. Smith and David Chiszar. UNC-MNH photographs 7–8. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc.).

Submitted by **CHAD MONTGOMERY, KEVIN WALDRON, JUSTIN HOBERT, RON DONOHO,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

THAMNODYNASTES HYPOCONIA (Cateye Coluber). ARGENTINA: BUENOS AIRES: Partido de Mar Chiquita, Parque Lago (37°45'20"S 57°26'40"W). 10 September 1994. F. Gonzalez. Verified by Jorge Williams. Herpetological Collection, Vertebrate Laboratory, Departamento de Biología, Universidad Nacional de Mar del Plata (UNMdP 610). First county record (Cei 1993, Mus. Reg. Sci. Nat. Torino Monogr. 14:949). Adult male captured in coastal sand dunes with grass cover; extends range 125 km S from nearest known locality in Punta Médanos, Partido Urbano de la Costa (Williams and Scrocchi 1994, Ofidios de Agua Dulce de la República Argentina. Vol. 42 Reptilia, Fasc. 3 Ophidia Lepidosauria. PROFADU-CONICET, La Plata. 55 pp).

Vagility and the Florida Distribution of the Cuban Treefrog (*Osteopilus septentrionalis*)

WALTER E. MESHAKA, JR.
Museum, Everglades National Park, 40001 SR-9336
Homestead, Florida 33034-6733, USA

The Cuban treefrog is a large, primarily mesophytic forest-dwelling hylid of the West Indies (Duellman and Schwartz 1958; Meshaka 1994a; Myers 1950). It is the only native hylid in Cuba and is sympatric with no other Caribbean hylids throughout its West Indian range (Schwartz and Henderson 1991). Assistance by humans has in recent times facilitated establishment of the Cuban treefrog on Ramey Air Force Base in Puerto Rico and on isolated islands of the Lesser Antilles (Powell et al. 1992; Schwartz and Henderson 1991; J. D. Lazell, Jr., pers. comm.). Shortly after being recorded in Miami (Schwartz 1952) dispersal of the Cuban treefrog through mainland Florida was rapid (Wilson and Porras 1983), and ecological versatility enabled it to successfully colonize natural and disturbed habitats (Dalrymple 1988; Duellman and Schwartz 1958; Meshaka 1994a).

By providing opportunity to disperse, vagility is a correlate of successful colonization for many species (Ehrlich 1989) and testable in the pattern of dispersal. Here, I present the historical and present-day distribution of the Cuban treefrog in Florida, interpret the pattern of its dispersal in light of its vagility, and compare my findings with the dispersal patterns of other colonizing species of reptiles and amphibians.

Dispersal of the Cuban treefrog through Florida took place in a temporal and spatial scattershot pattern. Most of its presently known northern range limits (Fig. 1) were realized by the mid 1970s (Table 1). Within 20 yrs of the Miami record (Schwartz 1952), it had dispersed northward to central Florida (and in two cases the panhandle) and mostly to sites that were distant from one another. Moreover, radiation was discontinuous in that dispersal to extreme sites often preceded dispersal to sites close to its source area of Miami. The rapid but discontinuous dispersal to presently recognized boundaries supports the assertion that the Cuban treefrog is vagile as predicted for successful colonizing species (Ehrlich 1989) and that, more so than by natural means, humans were the primary agent of its dispersal through Florida.

Similar patterns of dispersal are documented for other colonizing species for which humans have played the primary role in dispersal. For example, mechanized transport of equipment (military and otherwise) resulted in the successful dispersal of *Hemidactylus frenatus* in the Pacific Islands (McKeown 1978), *H. turcicus* in Texas (Davis 1974), and isolated dispersal events of *H. mabouia* and *H. garnotii* to sites in Everglades National Park (Meshaka, unpubl. data). Air traffic was a mode of dispersal for *Hyla squirella* to the Bahamas (Crombie 1972). In similar fashion, the Cuban treefrog, having colonized the now defunct Ramey Air Force Base in Puerto Rico (Schwartz and Henderson 1991), may have been transported on equipment. Dispersal of animals free on motorized vehicles is probably responsible for a disjunct population of *H. mabouia* in south-central Florida (Meshaka et al. 1994), and the source of repeated introductions of *Anolis sagrei* at Archbold Biological Station following conferences (pers. obs.). Similarly, dispersal on a trailer was the source of a nearly successful colonization attempt by at least seven Cuban treefrogs at one time to a ranch in south-central Florida (Highlands Co.) from Okeechobee Co. (Stan Pollack, pers. comm.). Five individuals residing in the awning of another trailer were dispersed from Highlands Co. to Sarasota Co. during an afternoon drive (Mary Hout, pers. comm.).

The plant trade has played a critical role in the colonization of *Anolis sagrei* throughout Florida (Godley et al. 1981), and the loose soil of nursery shipments carries *Ramphotyphlops braminus* (Meshaka 1994b) and *Eleutherodactylus planirostris* (Goin 1947) throughout Florida. The same could be true for *Gastrophryne carolinensis*, *Ophisaurus ventralis*, and *Diadophis punctatus* which are established in parts of the West Indies (Schwartz and

FIG. 1. Distribution of the Cuban treefrog (*Osteopilus septentrionalis*) in Florida. Solid circles denote locality records of voucher specimens collected 1991–1994 and deposited in the United States National Museum. Stars denote published records not included by locality records of this study.

Henderson 1991). The Cuban treefrog is easily dispersed in plant shipments. For example, on several occasions live individuals were uncovered in foliage shipments sent to the zoo in Toronto, Canada (K. Jackson, pers. comm.), and a gravid female (USNM 218509) was collected in Baltimore, Maryland on June 1927 in a shipment of bananas that originated in Cuba. However, the Cuban treefrog is most easily dispersed in cultivated palm trees, especially royal palms (Table 2), for two reasons. First, the moist confines of palm axils provide a suitable food base and refuge for habitation and dispersal. Second, palm trees are sent in large numbers to disturbed areas which meet, often in full, the simple life history requirements of this species (Meshaka 1994a).

Mechanized transport of palm trees may be a greatly accelerated version of dispersal in palm trees and other vegetation during hurricanes (Darlington 1938; King 1962), a natural phenomenon with which this species has evolved. Dispersal in the decapitated heads of palm trees, such as royal palm trees which are native to the West Indies, would be not at all surprising given the protective qualities of the palm bole. Further, successful colonization is probable after a natural dispersal event in light of a breeding response by the Cuban treefrog immediately following a hurricane in urban (Meshaka 1993) and natural (Meshaka 1994a) areas of extreme southern Florida. Thus, its success in passive dispersal stems from use of refuges in objects which are themselves dispersed naturally or analogously through the activities of humans.

Because of humans, transport of palm trees repeatedly introduces the Cuban treefrog to sites. Each dispersal event increases the chance for successful colonization which takes place at a faster rate than is naturally possible by either actively dispersing along the edge of a range or passively dispersing in a hop-scotch manner in hurricanes. The known sale of palm trees from Homestead, Florida to the West Indies and throughout Florida (e.g., Manuel Diaz Farm) could be responsible for similar colonization patterns of other species which, like the Cuban treefrog, inhabit palm trees (Table 2). In this regard, the trade of palm trees may now be added to the list of dispersal agents which accelerate the colonization process of *Hemidactylus garnotii* through Florida (Wilson and Porras 1983) and now the Bahamas; Abaco, Man 'O War Cay (Buckner and Franz 1994) and Nassau, New Providence Island (Meshaka 1995). The same may be said for the colonization of

TABLE 2. Numbers of amphibians and reptiles (excluding anoles) captured within the axils of cultivated palm trees from 1991 to 1994 in Florida and Nassau, New Providence Island.

Species	Queen Palm *Arecastrum romanzoffianum* N = 116	Royal Palm *Roystonea edata* N = 44	Total 160
Cuban treefrog (*Osteopilus septentrionalis*)	10	40	50
Green treefrog (*Hyla cinerea*)	0	1	1
Squirrel treefrog (*Hyla squirella*)	0	4	4
Indo-Pacific gecko (*Hemidactylus garnotii*)	11	2	13
Corn snake (*Elaphe guttata*)	3	0	3
Total number of animals	24	47	71
Number of animals/palm	0.20	1.10	0.44
Number of Cuban treefrogs/palm	0.09	0.91	0.31

Hyla cinerea and *H. squirrella* in disparate regions of the West Indies (Schwartz and Henderson 1991) as well as the dispersal of *Elaphe guttata* on Grand Cayman Island which was suspected of having been associated with foliage trade from Florida (Franz et al. 1987). Like the dispersal of the Cuban treefrog through Florida, these north temperate invaders of the West Indies could be expected to have a higher probability of colonization success with increasing frequencies of dispersal events in large numbers of palm trees.

For the Cuban treefrog, foliage-mediated dispersal between Florida and the West Indies creates a reversal of source and target areas, a dimension to the colonization process infrequently realized by geographically-expanding species. One outcome of this phenomenon is the colonization and/or recolonization of West Indian sites from Florida. For instance, the second record of the Cuban treefrog on the British Virgin Islands, collected by J. D. Lazell, Jr. in October 1993, came from Necker Island whose introduction was associated with importation of nonfumigated ornamental plants from Miami to a private development on the Island (J. D. Lazell, Jr. pers. comm.). Arguably, cargo ships suspected by Barbour (1931) of dispersing the Cuban treefrog from Cuba to Key West may well have been sending some back to Cuba. A second outcome of source-target-site reversal is genemixing through the introduction of Florida specimens to established populations in the West Indies. For example, 75 queen palm trees searched on Nassau in November 1992 (Table 2) were known to have originated from Manuel Diaz Farm as part of a beautification project. In May 1992, 57 Cuban treefrogs were collected from 619 palm trees in a grove at Manual Diaz Farms. Most of the trees were queen palms but some solitaire palms (*Seforthia elegans*) were also present.

Thus, the Cuban treefrog is a vagile species and its opportunity to disperse is enhanced by activities of humans (trade of palm trees) which are analogous to natural processes. The rapid and haphazard pattern of its dispersal is in keeping with that of its primary agent of dispersal, and these patterns are also evident in other colonizing species whose recent range expansions can be associated with similar dispersal agents. The population increase at introduced sites enforces the overall success of the Cuban treefrog by providing a new source from which to populate or repopulate native and introduced areas.

Acknowledgments.—I am grateful for permission to collect at Manual Diaz Farms, and to B. P. Butterfield and J. B. Hauge for field assistance.

Museo de Zoología, Facultad de Ciencias
Universidad Nacional de México Autonoma
Apartado Postal 70–399, C. P. 04510, México Distrito Federal, México

The common house gecko (*Hemidactylus frenatus*) is not indigenous to México, but apparently arrived from the Pacific islands (Java) (Smith and Taylor 1950, Bull. U.S. Nat. Mus. 199:1–253). This lizard was previously reported from Guerrero (Smith and Taylor, *op. cit.*), Yucatán (Marcellini 1971, Southwest. Nat. 15:397; Lee 1980, Univ. Kansas Nat. Hist. Mus. Misc. Publ. 67:1–75), Sinaloa, San Luis Potosí, Colima, Oaxaca, and Chiapas (Smith and Smith 1976, Synopsis of the Herpetofauna of Mexico. Vol. III. John Johnson, North Bennington, Vermont. 977 pp.), Baja California Sur (Reynoso 1990, Herpetol. Rev. 21:22) and Morelos (Castro 1987, Bull. Chicago Herpetol. Soc. 22:69–70).

Hemidactylus frenatus was probably introduced in México through Acapulco (Weeb 1972, British J. Herpetol. 4:267–268) via shipping port activity, and has expanded its range into tropical and subtropical zones in both versants of the country, successfully colonizing other areas, mainly urban centers.

Herein, we document the establishment of *Hemidactylus frenatus* in eight Mexican states. All specimens collected by the authors are deposited in the Museo de Zoología, Facultad de Ciencias, Universidad Nacional de México Autonoma (MZFC). Other specimens are deposited in the collections of the Instituto de Biología, Universidad Nacional de México Autonoma (IBH), and Texas Cooperative Wildlife Collection (TCWC). Adrián Nieto and Michael J. McCoid kindly verified the identifications. The records are:

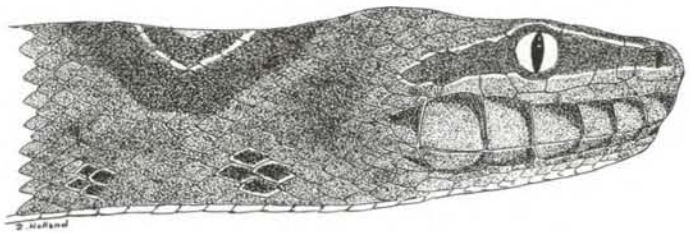
CAMPECHE: Municipality of Carmen, Escárcega. 122 m elev. 11 October 1993. MZFC 6620; Ciudad del Carmen. 11 March 1982. IBH 3488; Municipality of Campeche, Campeche (19°53'29"N, 90°27'54"W). 195 m elev. 11 October 1993. MZFC 6619.

HIDALGO: Municipality of Huejutla de Reyes, 10 Km N of Huejutla (21°05'01"N, 98°27'54"W). 290 m elev. 14 November 1993. MZFC 6288.

JALISCO: Municipality of Tomatlán. 15 August 1993. MZFC 6111–6112; Municipality La Huerta, Chamela (19°30'N and 105°03'W). 21 July 1983. TCWC 61705–61707.

NAYARIT: Municipality of Tuxpan. 14 July 1994. MZFC 6764.

QUERÉTARO: Municipality of Jalpan, Jalpan. 860 m elev. 10 October 1993. MZFC 6625.



QUINTANA ROO: Municipality of Isla Mujeres, Isla Mujeres. 20 December 1991. MZFC 6109.

TABASCO: Municipality of Centro, Villahermosa. August 1987. IBH 6852; Municipality of Cárdenas, Cárdenas, Hotel Rivera (15°39'38"N, 93°22'32"W) 23 m elev. 9 October 1993. MZFC 6615–6616.

VERACRUZ: Municipality of Veracruz, Veracruz. 31 May 1987. IBH 6851; Municipality of Catemaco, Catemaco. 14 June 1991. MZFC 5830; Municipality of Coatzacoalcos, Coatzacoalcos. 14 July 1993. MZFC 5921.

The invasion of new territory by this gecko is often the result of human activities (Meshaka et al. 1994. Herpetol. Rev. 25:127–128). Apparently, it is also aided by natural phenomena, like hurricanes (pers. comm. from inhabitants of some of the localities here recorded). The presence of this lizard may have a negative effect on indigenous gecko populations of other genera (e.g., *Sphaerodactylus*) because its feeding habits include cannibalism and presumably it is a potential predator.

BOOK REVIEWS

Turtles of the United States and Canada, by Carl H. Ernst, Jeffrey E. Lovich, and Roger W. Barbour. 1994. Smithsonian Institution Press. (Dept. 900, Blue Ridge Summit, Pennsylvania 17294, USA), xxxviii+571 pp. US $60 (cloth bound), ISBN 1-56098-346-9.

PETER MEYLAN
Natural Sciences, Eckerd College
St. Petersburg, Florida 33711, USA
e-mail: meylanpa@eckerd.edu

This book is a considerable enlargement and revision of Ernst and Barbour's (1972) *Turtles of the United States*. Jeff Lovich has joined Ernst and Barbour in the revision. The text is a very complete compilation of the published literature on the 56 species of turtles (54 native and two introduced) that occur in the United States and Canada and their adjacent waters. The authors have made a monumental effort to assemble, sort, and report in a concise and organized fashion, the huge amount of data on North American turtles that is available in the primary literature. Their survey is remarkably complete through 1992 and, with rare exception, they have accurately presented the findings from the primary literature. The book includes an extensive bibliography (almost 90 pages) of work that was published between 1970 and 1992. The reader is referred to Carr (1952) and Ernst and Barbour (1972) for most earlier citations.

The book includes only 16 pages about turtles in general, a four-page key to North American forms, a three-page glossary of scientific names, and the bibliography. The body of the text (470 pages) consists of 56 species accounts. Most accounts include sections on recognition (identification), karyotype, fossil record, distribution, geographic variation, confusing species, habitat, behavior, reproduction, growth and longevity, food habits, predators and defense, populations, and remarks. Each is accompanied by black-and-white photographs that typically include dorsal and ventral views of the shell and a close-up of the head. For many species, geographic and ontogenetic variation is illustrated in appropriate photos. A set of color plates includes one view of every species. The quality of the photos is highly variable; too many of the black-and-whites are too dark or too shadowy. The authors should have exploited the generosity and photographic skills of the turtle research community rather than attempt to use their own materials in nearly every case.

An important aspect of this large text is that the authors are consistent in their organization. Information is organized in like fashion from account to account. Where data are lacking, that is also carefully pointed out. These features greatly enhance the value of this book and make it a very handy reference.

It is unfortunate, however, that the authors did not use this occasion to summarize observations at levels other than that of the species. I found it surprising that they did not feel compelled to summarize features common to higher taxonomic groups (e.g., families and genera). Such summaries for the family Emydidae or speciose genera like *Graptemys* or *Gopherus* would have been particularly useful.

The authors have obviously read a small mountain of literature and have done an excellent job of summarizing, organizing, and presenting the efforts of hundreds of authors working in a remarkable diversity of disciplines. Given the size of the task, it seems inevitable that some errors would creep in. The only obvious error that I found from the ecological literature is the citation of Marchand (1942) for the abundance of *Sternotherus minor* in Rainbow Run, Marion Co., Florida, when he did not find it there at all (Meylan et al. 1992; Marchand, pers. comm., 1990). Otherwise, my impression of the ecological, behavioral, and physiological treatments is that they are accurate, remarkably complete, and extremely useful.

The only serious problems that I encountered are in the areas of systematics and morphology. The view of turtle systematics presented in the introductory material is outdated. We are told in the karyology section that greater similarity means closer relationship. In the section on turtle evolution we are told that turtles evolved a shell. Turtles are defined by the presence of a shell. Exactly what it was that produced a shelled form is still debated (Laurin and Reisz 1995; Lee 1993), but before it had a shell, it was not a turtle.

If the Pleurodira and Cryptodira are sister groups, one can't originate in the Jurassic and the other in the Cretaceous (p. xx). In fact, if *Proterochersis* is a pleurodire (Fraas 1913; Gaffney and Meylan 1988; Gaffney et al. 1991; but see Roogier et al. 1995), then both pleurodires and cryptodires are Triassic in age. The authors also seem to reject the notion that living sea turtles, including the Dermochelyidae, are each others' closest relatives. Instead they recognize a Dermochelyoidea equivalent in rank to the Chelonioidea (which they restrict to the Cheloniidae without comment) and the other three living cryptodire superfamilies. This is a significant throwback because it implies that *Dermochelys* could be the sister group of other cryptodires when it is now well established that it is a highly derived chelonioid. It seems likely that these issues in higher turtle systematics will not be very relevant to the average user of this text.

Another systematics issue, the inconsistent use of the name Emydidae, certainly is. The authors switch between a broad and a narrow definition for the family name Emydidae, even in consecutive lines, without advising the reader! They use the name in the broad sense (Emydidae plus Bataguridae of Gaffney and Meylan 1988) in some places (xviii; p. 203, line 2) but in the narrow sense (New World "pond turtles" minus *Rhinoclemys*, plus *Emys*) in others (p. xxi; p. 203, line 1, p. 204). Readers will be mislead if they interpret the statement on p. 203 that "formerly the family was divided into two subfamilies...Batagurinae...and... Emydinae," as a suggestion that these authors are always using the term Emydidae in its restricted sense.

Certainly the most troubling systematic statement for this reviewer is the use of the generic name *Trionyx* for three North American and two introduced Asian softshells. I would expect that these authors should be sympathetic to my desire to reveal the relative relatedness among what was formerly included in the genus *Trionyx* (Meylan 1987). After all, every one of their species accounts includes a section on geographic variation in which the reader is informed as to whether or not subspecies have been recognized. In some cases, a number of pages and a series of figures are devoted to making sure that the reader realizes that a given species is variable; that it is not the same entity throughout its range. My systematic revision of the Trionychidae (Meylan 1987) was an effort to make the same point at a much higher level. *Apalone* (the three North American species) is clearly a monophyletic group. Although it is in the same tribe as the type species of *Trionyx* (*Trionyx triunguis*), it is not the sister group of this species. Its sister group is a pair of large, Old World, riverine forms, *Rafetus euphraticus* from the near East, and *Rafetus swinhoei* from China. *Trionyx* (sensu stricto) is the sister group of *Apalone* plus *Rafetus*. *Apalone* appears to have been present as

early as the late Cretaceous (Gardner et al. 1995) which suggests that it may have been an independent entity for almost half the history of turtles. Morphologically and biologically, *Apalone* is far more distinct from *Rafetus* and *Trionyx* (sensu stricto) than *Emydoidea* is from *Emys* or *Chrysemys* is from *Pseudemys*. If we continue to use the generic name *Dogania* for the most flexible of softshells, then use of the name *Trionyx* for *Pelodiscus sinensis* and *Palea steindachneri* would make *Trionyx* paraphyletic. If these authors advocate using *Trionyx* for *Dogania*, I wonder if they would also advocate using *Testudo* for *Gopherus* and *Coluber* for *Lampropeltis*. My guess is that the opinions of the authors are colored by an emydocentric view of turtle diversity in which the great morphological distance of trionychids from emydids overshadows the variation within this highly divergent family.

A number of errors in descriptions of turtle morphology should be pointed out. They have used the term internal posterior cortical canal (p. xx) for the internal carotid canal. They describe the palatine of turtles as single and paired in the same paragraph (p. xxiv); they are always paired. The structures in the figure on page xxv labeled "nares" are in fact the posterior palatine foramina and the bone labeled as the premaxilla in the dorsal view is actually a portion of the maxilla. The structure labeled "zygomatic arch" in the same figure should be labeled jugal bar. Use of the former term implies homology to a structure in synapsids and should be avoided. The statement that the premaxillae separate the internal nares and the palatines in cheloniids suggests that they are being confused with the vomer. And anyone who suggests that cheloniids have lost the ability to retract the neck has never known the pleasure of trying to collect blood from the cervical sinus of a recalcitrant loggerhead.

In the trionychid section (p. 103), the treatment of the bones of the anterior lobe of the plastron is likely to increase confusion about the homologies of these elements. The authors attempt to follow Williams and McDowell (1952), who thought that the entoplastron was absent from trionychids, that the single midline element anterior to the hyoplastra was a fused epiplastra, and that the two anterior-most elements were neomorphs (that they called preplastra). However, the figure on page 104 fails to follow this terminology. What are now considered to be the epiplastra (Meylan 1987:11; Bramble and Carr, ms.) are labeled both as the epiplastra and preplastra, and the entoplastron (fused epiplastra of Williams and McDowell 1952) is unlabeled.

The authors do not appear to be well versed in the terminology of molecular genetics. They say that Hawaiian *Chelonia mydas* are similar to some Atlantic populations, but "differ by having five restriction enzymes." They also miss the critical point that it is natal homing and not nest-site fidelity that leads to genetic differentiation among populations in this species.

To be fair, it seems unlikely that these authors envision their work as a systematic or morphological treatise. Rather, they have set out to summarize the ecological, behavioral, and physiological literature on North American turtles. By doing this at the species level they have taken the most conservative approach, and they succeed admirably.

Publication of this book provides an opportunity to examine the extent of knowledge of the North American turtle fauna. With about 470 pages of species accounts, the average account is nearly eight-and-a-half pages. Considering the layout of the book, the size of the font, and the concise nature of the presentation, one could come to the conclusion that we know a great deal about North American turtles. As one might expect, however, the treatments are not nearly equal in length. The longest are those on *Chelonia mydas* and *Chrysemys picta* (21 pages each). The shortest is *Trionyx* [*sic*] *steindachneri* (2 pages). Chelydrids receive the most attention, with an average of 14 pages per species. Among native forms, kinosternids get the shortest treatments with 7 pages per species. Half the book is devoted to the Emydidae, but this is as it should be because this family represents more than half (57.4% by species) of the native fauna. It is interesting that among native turtles, it seems to be a series of Gulf Coast emydids that are most poorly known. Most of these are sibling species that have only recently been recognized and insufficient time has passed for the accumulation of much literature.

Having recently had occasion to summarize the available data for a series of Old World trionychids, it is easy to say that, by comparison, most North American forms are very well known. In fact, the depth of scientific knowledge for certain species is truly remarkable. It is not surprising that widespread forms like *Chelonia mydas, Chrysemys picta, Trachemys scripta, Terrapene carolina,* and *Chelydra serpentina* appear to be the best known. It is these forms that have received the most attention from physiologists and it is their contributions which add significantly to the length of the longest accounts in this book.

Although there may be a few problems with this book, overall it is a monumental work. It will undoubtedly serve as the standard reference to North American turtles for the next generation of biologists. Every serious vertebrate biologist on the continent will want a copy.

e-mail: karns@alpha.hanover.edu

The analysis of the distribution and abundance of organisms is at the core of the science of ecology. It is therefore a significant event when a distinguished group of international authorities on amphibian biology produce a volume such as *Measuring and Monitoring Biological Diversity: Standard Methods for Amphibians*. In this handbook, standard methods for assessing the distribution and abundance of amphibians are described, and the research community is asked to follow those procedures to insure comparability of studies across space and through time. Because of its authoritative credentials and the quality of the book, this volume will be studied, used, and cited by a wide variety of investigators and students in all parts of the world. This is the first production in the Biological Diversity Handbook Series from the Smithsonian Institution Press. Based on the high standard of quality set by this first handbook, forthcoming volumes will be eagerly awaited.

The book contains ten chapters, an impressive set of appendices, a glossary, and 22 pages of literature citations. This volume will be regularly taken off the shelf as a reference book for teaching and research. The foreword by David B. Wake and the preface by the editors explain the historical development of the book and its relationship to concern over declining amphibian populations. Chapter 1 briefly discusses the biodiversity crisis, the rationale for the book, its historical predecessors, and the intended audience. Chapter 2 is a concise and informative overview of amphibian biology. The next two chapters discuss basic aspects of research design and statistical concepts in the construction of amphibian studies. Lee-Ann C. Hayek and the editors have done a heroic job of trying to clearly distill the basics of research design and pertinent statistical concepts and procedures into a manageable space in these chapters, but this will be a difficult section of the book for some readers. I found the discussion of statistical significance (always a problem for students) to be particularly clear.

Chapter 5 provides advice on research planning and methods for collecting data on a wide variety of important factors collateral to the study of amphibians. Topics range from measuring weather variables, to microhabitat description, to automated frog call recorders. The discussion of data loggers deserves special attention. Chapter 6 is the biological core of the book and presents ten standard techniques for inventory and monitoring. Based on my particular field experiences and biases, I think the authors' choice of methods covers all the reasonable bases. This will be the chapter turned to most often. The presentation of each technique follows a standardized format and gives the reader basically everything that is needed (material and intellectual) to initiate a study using that method. Chapter 7 is an interesting assemblage of supplemental techniques not conveniently covered among the ten techniques described in Chapter 6, including use of thread bobbins for tracking, night driving surveys, and use of field trips for data acquisition. One of the pleasures of this volume is that the methods in these chapters are described in sufficient detail to allow someone to actually go out and do them. Reading these accounts is like having a conversation with someone who has "been there, done that," and you trust the advice.

Chapters 8 and 9 return to data analysis. In Chapter 8 the authors clearly "walk" the reader through several widely used techniques for estimating population size. I think readers will find the summary of the analysis of biodiversty data in Chapter 9 to be quite useful. There is a bewildering jungle of coefficients and statistical tools out there for making comparisons; the important ones are presented here in a clear and practical fashion. The population estimate and biodiversity analysis chapters are both made eminently more "user-friendly" by the use of examples with sample data sets. The last chapter closes with conclusions, recommendations, and a statement of the philosophy of the editors regarding the adoption of the proposed standard methods. The next 49 pages are devoted to a series of useful appendices on handling and marking amphibians, recording frog calls, and whole specimen and tissue preservation techniques. There is a list of vendors and even a step-by-step random number table.

A book like this should really be assessed by several reviewers; the volume covers so much territory that multiple appraisals would be useful. In general, I think the handbook is remarkably ambitious and very successful in achieving its objectives. The production quality is high and the book is essentially free of typographical errors. It is reasonably priced (the paperback edition is a real bargain). The editors have done a good job of melding together the styles and content of sections by many authors. Perhaps inevitably, there is some redundancy in topics. The handbook has excellent data-based examples in a number of sections; however, in future editions I would like to see even more examples and problem sets. I think these teaching aids greatly increase the utility of the volume for a wider audience.

Throughout the handbook, authors acknowledge predecessors to this volume (e.g., Campbell and Christman 1982; Corn and Bury 1990; Davis 1982; Vogt and Hine 1982). However, more successfully than anything else available, this handbook pulls together a large and diffuse literature on field techniques and statistical methods into one convenient package. The authority of the handbook is greatly increased by the committee approach taken by the editors. The methods presented here represent a consensual agreement among a pool of knowledgeable participants, thus avoiding individual methodological biases. The special attributes of amphibians demand both terrestrial and aquatic sampling procedures. Because of this, workers dealing with a variety of other taxa will find this to be a rich source of information and a stimulus for the cross-fertilization of methodological ideas.

The first chapter states that the book provides recommendations and guidelines for the inventory and monitoring of amphibian populations, and the authors discuss the need for the standardization of methods. In the final chapter (p. 272) this point is more strongly stated: "We urge, therefore, that all users follow to the letter the procedures indicated." I agree with the authors that there is a need for the standardization of methods, and the value of standardization is illustrated by important studies such as Pechmann et al. (1990) and Inger and Voris (1993). The handbook asks the research community to voluntarily adopt a set of standards, and as a result of the publication of this volume, we are now engaged in an interesting experiment. To what degree will this book's recommendations be put into effect by the assortment of investigators (government, academic, private) that deal with questions of biodiversity measurement and monitoring? The natural world is inherently messy, and researchers will not always be able to follow certain idealized methods of collecting

data "to the letter." Experienced researchers will design programs best suited to their particular needs. The authors of the handbook recognize this reality, and in the last chapter they propose a feedback mechanism by which demonstrated methodological improvements can be incorporated into future editions. At the other extreme, less experienced researchers, perhaps uncertain of their planning and judgment, may try to use this volume as a "cookbook" and attempt to ram a survey or monitoring problem into one of the available options, even if the fit is not particularly good. In any event, accurate documentation of all procedural aspects of a research project is mandatory. For standardization of methods to become a reality there must be a general awareness of the handbook and it must be used. I asked several individuals involved in biological survey work for reputable environmental firms if they were aware of this volume—they had not heard of it (but have now ordered copies).

In Chapter 1 (p. 3) the editors state that the handbook is intended to be "comprehensive so that individuals with an undergraduate degree in science, or equivalent training, can measure the biological diversity of amphibians using only this volume." I have used this book with students and discussed its use with a number of biologists who have undergraduate or Master's degree level backgrounds coupled with job training. In general, they report the handbook to be an extremely valuable resource, but they do have problems with its use. They appreciated the clear descriptions of specific field methods and guides to resources, but some encountered difficulties with aspects of research planning and design, statistical methods, and using statistical thinking in making methodological decisions. This is not a criticism of the book's content; as I noted earlier, I think the authors did an excellent job with these basic research topics, but this book cannot be, nor is it intended to be, a substitute for training in population and community ecology and biostatistical thinking. The numerous references in the handbook will allow the reader to pursue topics in greater detail as needed. Investigators in need of assistance should seek expert advice.

In talking and listening to some of the authors of this volume, it was obvious that they were excited about being involved in a project that has the potential for making an important and lasting contribution to the study and conservation of amphibians. I especially like the populist philosophy that runs through this book—the intent is to be inclusive, to get interested people working together and doing good science. This effort demands that we tap into the large reservoir of interested persons, who are not specifically trained in biology, but just interested in the natural world (as is already being done in a number of research programs). These "citizen-scientists" are more than willing to go out on cold spring nights or hot, humid tropical nights on lonely roads with notebook and tape recorder in hand to document what is there. In the long run, the collaboration that is forged between these individuals and the scientific community may be one of the most important outcomes of this and similar projects. I applaud the editors and authors of this important book on a job well done.

The scientific study of biological diversity in tropical Asia is in its infancy. In the midst of efforts to protect biodiversity, concerns have been expressed of the loss of expertise in systematic research and the retarded growth of systematic knowledge, surely the cornerstone of biological conservation. We don't even know which vertebrates occur in the region, far less the higher relationships between taxa. This, in turn, may potentially result in species loss: the failure to recognize distinct species is known to have caused species extinction (Daugherty et al. 1990).

Systematic research, which is poorly funded in India, is carried out almost exclusively by the staff of the Zoological Survey of India (ZSI), drawing upon the extensive collection started by the Asiatic Society of Bengal, although much has since been added by the Survey's own expeditions throughout the country, and even occasionally beyond our frontiers. This research has led to a virtual explosion of publications by its staff, primarily in the periodicals issued by the Survey (notably the Records, the Memoirs, and the Occasional Papers) as well as illustrated books (such as the Handbook series, which has covered arachnids, freshwater molluscs and turtles), brought out by the ZSI as a service to furthering our understanding and appreciation of India's rich and diverse fauna.

As might be expected, given an organization with a staff of over 1,000 and the lack of rigorous peer review, the quality of the work is highly heterogenous. Studies by the Survey have resulted in fundamental understanding of the biology and biogeography of our land (e.g., the Satpura Hypothesis of Hora, 1949). On the other side of the coin however, several major errors in the description of species purported to be new, many of which are not based on adequate series, are also attributable to the work of the Survey.

The goal of the Handbook series is to enable the man on the street to identify the Indian species. If the present work, written by an arachnologist (Tikader, a former Director of the ZSI, now deceased) and a herpetologist (Sharma, previously Deputy Director of the ZSI, now retired) is meant to help the layperson identify the local lizards and learn some basic facts about their biology, their objectives have not been realized. The mistakes begin on the cover of the dust jacket (similar to the book on turtles by Tikader and Sharma, 1985) of a male *Calotes versicolor* perched on *Cissus quadrangularis*, a xeric region plant, identified as "*Salea horsfiedi*" (sic), a species from the wet evergreen forests of the Western Ghats.

The introduction includes a general review of the biology of lizards—their ancestry, morphology, diet, reproduction, and a rather lengthy discussion on their distribution. Also included is a key to the families of Indian lizards. The core of the book deals with the lizards themselves. Each family section starts with a dichotomous key to the genera and is followed by species accounts. For each species, the authors provide an English name, the scientific name, authority, and date. The heart of the species section are the descriptions of the lizards, which are little different from what we already know from M. A. Smith (1935). The distributional notes contain details of ranges within India and outside (where applicable). "Habits and Habitat" include fragmentary natural history data, and status for most species is 'rare,' 'indeterminate,' or 'in abundance,' although for some species status has been categorized as 'rare, indeterminate.' The authors add two species to the Indian fauna: *Phrynocephalus reticulatus* (from Ladak [sic], Kashmir) and *P. euptilophus* (from Western Rajasthan).

The plates are organized into a set of barely passable black-and-white photos, followed by color photos, the best of which are appalling. Some of the photos apparently have been photographed directly from the concise book on the Indian reptiles by Daniel (1983). A great number of the species are illustrated by museum specimens that are mere black blobs against a white background. One (*Eremias gutulata watsoniana*) is printed upside down. Typos are unacceptably high throughout, even in the plate captions. The line drawings, being mostly borrowed from older works such as Smith (1935), are useful and have printed well. Some of those that are new have problems. For instance, the text-figure of *Riopa ashwamedhi* (Fig. 25: 150), a species described by Sharma himself, shows a Martian-like figure, making one wonder whether the authors take herpetology seriously. The maps showing the distribution of our lizards deserve particularly harsh comment. Ranges are marked arbitrarily with polka dots, checks, stripes, and the authors' other favorite designs; these are amateurish and distracting. More seriously, they are inaccurate. One example is the map (No. 17: 210) showing the distribution of the gekkonid *Hemidactylus brookii*. We know from Smith that it is widespread in India, but Tikader and Sharma cover the whole of mainland India with their choice of hatching, without critically trying to ascertain the true distribution points and natural discontinuities, while omitting the species from adjoining Nepal and Bangladesh. The range of *Uromastyx hardwickii* is shown right down into the Indian peninsula, in a map (No. 21: 214) it shares with a variety of unrelated lizards including the geckos *Lophopholis* (now *Hemidactylus*) *scabriceps*, *Gehyra mutilata* and another agamid, *Calotes grandisquamis*.

Valid species of lizards whose occurrence in India are indisputable that have been omitted in the work are so numerous that these have been listed by family below:

Gekkonidae

Alsophylax boehmei Szczerbak 1991
Cnemaspis boiei (Gray 1842)
Cnemaspis nairi Inger et al. 1984
Cnemaspis tropidogaster (Boulenger 1885)
Gekko verreauxi (Tytler 1864)
Cyrtodactylus himalayanus Duda and Sahi 1978
Cyrtodactylus malcolmsmithi Constable 1949
Cyrtodactylus mansarulus Duda and Sahi 1978
Cyrtodactylus pulchellus Gray 1828
Cyrtodactylus walli Ingoldby 1922
Hemidactylus mahendrai Shukla 1983
Lepidodactylus lugubris (Duméril and Bibron 1836)

Agamidae

Laudakia melanura (Blyth 1854)
Laudakia pakistanica (Baig 1989)
Salea kakhiensis (Anderson 1878)

Scincidae

Ablepharus pannonicus Fitzinger in: Lichtenstein in: Eversmann 1823
Dasia halianus (Halys and Nevill 1887)
Dasia subcaeruleum (Boulenger 1891)
Eumeces blythianus (Anderson 1871)
Eumeces schneideri (Daudin 1802)
Mabuya clivicola Inger et al. 1984
Mabuya gansi Das 1991
Mabuya rudis Boulenger 1887
Ophiomorus raithmai Anderson and Leviton 1966
Scincella macrotis (Steindachner 1869)
Sphenomorphus reevesi (Gray 1838)

Lacertidae

Acanthodactylus blanfordii Boulenger 1918

In summary, 27 species are missing from a work purported to be a comprehensive guide to the Indian saurians. However, included in the work is the so-called "luminous gecko," *Cyrtodactylus madarensis* Sharma, 1980, which was shown to be synonymous with *Eublepharis macularius* by Das (1991).

The text itself is not free of errors. A detailed listing is impossible, and would probably result in another tome. A sampling would be more interesting and is within the scope of the review. The distribution of the skink *Tropidophorus assamensis* is given as "India: Assam" (probably a result of direct transcription from Smith, 1935), whereas after the partition of India, part of Assam from where the types of the species came, became Bangladesh's Sylhet district, and the species has not been collected from within the boundaries of the Republic of India. The map for the species (No. 26: 219) shows its occurrence in the Khasi Hills of Meghalaya), the basis of which is not mentioned. *Varanus salvator*, the water monitor, is listed as being in Schedule I of the Indian Wildlife (Protection) Act (it is in Schedule II). *Gekko smithii* is indicated as occurring in the Andamans. The species that does occur in these islands is *G. verreauxi*, as shown by Ota et al. (1991), although *G. smithii* has been reported (Ota et al. 1991) to occur within Indian limits—in the adjacent Nicobar Islands. Its extralimital range is also wider than "Malaysia up to Patani in the north" indicated in the text, being recorded from the Sundas.

The bibliography lists most important pre-1935 literature, with those published subsequently being mostly the papers of the staff of the ZSI or the occasional papers from the Journal of the BNHS. The large volume of literature published on, or having relevance to, Indian lizards in foreign journals is missing.

In summary, this work has the hallmarks of the country's premier scientific institute's recent series of publications on reptiles: unedited, poorly illustrated, and obviously unresearched information. Being printed on good quality paper and well bound, it is likely to fool into complacency the bureaucrats who hold the strings of the research purse.

Considering cutbacks in funding for basic research in India, and the perpetual complaints by the staff of governmental agencies of the lack of funds for conducting biological investigations, one wonders how such books continue to see the light of the day. It apparently went unrefereed, was written in great haste, and without consultation with colleagues outside the ZSI or the recent literature. Several of the types of Sharma's new lizard species are at present "not available" at the ZSI, frustrating researchers in sys-

tematics. And lastly, it is alarming to read from the dust jacket that the second author is "now actively engaged in writing Fauna of India on Reptiles" (sic).

Princess Anne, Maryland 21853, USA
e-mail: druby@umes-bird.umd.edu

The goal of this book was to compile the literature on North American tortoises, broaden knowledge about tortoises, and improve the scientific rigor of studies on these species. The last such compilation was also by one of the editors of this book (Bury 1982). The book presents a wide-ranging set of reviews of the ecology and management issues related to the four tortoise species. (The full bibliography is listed in Herpetol. Rev. 26:7–8). As such, it represents an excellent source of current information about the four tortoise species, comparing some ecological requirements between species, and indicating fruitful directions for future research. The book contains two papers on classification issues, four on the distribution and habitat use of tortoises, one status report on the endangered species *Gopherus agassizii*, and two papers each on the topics of reproduction, burrow use, and life history. A closing critique of the status of knowledge about North American tortoises completes the volume by summarizing current knowledge and outlining the problems with present literature.

The first two papers, by Crumly, and Crumly and Grismer, examined the phylogenetic status of the genus *Gopherus*. In a cladistic analysis using PAUP and MacClade, they concluded that the genus was monophyletic. The second paper concluded that *Xerobates lepidocephalus* from Baja California was actually a specimen of *G. agassizii*. Mushinsky and McCoy tested for the effect of isolation of small populations of gopher tortoise on population size and distribution. They concluded that gopher tortoises need open types of habitats altered by fire. The rapid increase of the human population in Florida is producing fragmentation of the habitat which can result in local extirpation of populations.

The next series of papers compared habitat patterns of different species and within species but at different locations. Fritts and Jennings examined *G. agassizii* in México. Interestingly, they found populations were most common where rainfall exceeded 100 mm, a sharp contrast to the conditions in the northern range of this species (Sonoran and Mojave deserts). An informal census indicated that local peoples used the tortoises for food. They concluded that collecting was not yet a major factor on populations although it occurred near some towns in México. Bury, Esque, DeFalco, and Medica evaluated the status of *G. agassizii* in the eastern Mojave Desert, focusing on habitat use and pointing out the relationship between tortoise activity and soils which can support burrow construction. Densities on middle and upper slopes are poorly known, leading to possibly misleading perceptions about the tortoises' use of only lowland and flat areas. Germano, Bury, Esque, Fritts, and Medica considered the range and habitat of *G. agassizii* and what factors determine density. The wide range of environments used by this species challenges our understanding of tortoise needs and raises the question of how much flexibility in ecological requirements exists in this species. Corn reported on population trends on *G. agassizii* in the Mojave Desert. Population estimations were based on 60-day censuses on small plots. Unfortunately, as Corn pointed out, these procedures violate the assumptions of the Lincoln-Peterson Index and the actual numbers are not reliable. As indicated by the data presented, few sites have been studied more than five years—a short period in the life of an organism with a life expectancy of 50 years—and most have been visited only sporadically. The seven permanent sites listed in this paper need thorough, annual censuses before trends are clear. There is a poor understanding of how tortoise populations respond to environmental conditions, including fluctuations in precipitation such as the five-year drought in California which ended in 1993. None of the articles considered the possibility that the recent population declines in the western Mojave were a direct effect upon *G. agassizii* of such an extended period of low precipitation and therefore greatly reduced forage. It is quite possible that the physiology of *G. agassizii* has been selected for surviving annual droughts but the frequency of multiple-year droughts may be rare enough that this survival strategy produces a catastrophic decline in populations during long-term droughts (Ruby et al. 1994).

In a different direction, Oldemeyer compiled information on the effect of cattle and sheep grazing on desert tortoises. Despite substantial reductions in cattle numbers since 1934, the quality of most rangeland in the Mojave Desert continues to be rated poor by the U.S. Bureau of Land Management. As Oldemeyer indicated from his literature search, there have been few adequate studies on the effects of grazing in the Mojave Desert and most of the research reports he cited were unavailable or unreviewed. Because the diet, which is driven by precipitation patterns, varies from site to site and year to year, it is very difficult to generalize about dietary overlap between cattle and tortoises. One study (Turner et al. 1981) tested the effect of enclosures for two years, too short a time period for answering questions about the ability of the range to recover from grazing. Although this issue needs a detailed long-term test, political pressures have prevented the BLM from funding such a large scale project to obtain a more meaningful answer.

The next series of papers looked at physiological and developmental aspects of tortoises. Esque and Peters provided a well-documented report of their direct observations of stone and bone

ingestion. The importance of calcium in the diet of tortoises seems obvious; however, specific requirements for proper health are currently unknown. They recommended that managers leave bones and skeletons to weather in the field as a calcium source. The weathering process improved the desirability of the bones to the tortoises. Linley and Mushinsky provided experimental data on the eggs and hatchlings of the gopher tortoise (*G. polyphemus*) and found that the larger eggs produced larger hatchlings. Their data provide key parameters for estimating energy budgets in tortoise populations. Diemer and Moore reported on a six-year study on the reproduction of *G. polyphemus* in Florida. They outlined the phenology of this population and the relationships between egg diameter and clutch size with median carapace length in females. They concluded that estimates of minimum production of hatchlings cannot be evaluated against actual population counts because juveniles were hard to find, not as active, and small in size. These factors mitigated against successful sightings and captures of hatchling and juvenile tortoises.

Tom reported on microhabitat use and burrow activity in the Bolson tortoise (*G. flavomarginatus*). As the largest species of *Gopherus* and with a limited range in the Chihuahuan Desert, it is susceptible to disturbance. She found less burrow changing in the drier season than the wet. Juveniles produced their own burrows preferentially. Built under vegetation such as *Opuntia*, the burrow served as a microclimate shelter, provided shade and temperature control, and protected against predators.

Wilson, Mushinsky, and McCoy used radiotelemetry to study juvenile gopher tortoises. They hypothesized that the small home range of juveniles is a result of predator avoidance. There is a need to know the heating and cooling rates of juveniles in order to estimate the thermoregulatory effects of juvenile activity. Morafka looked at tortoise neonates in general. He contrasted tortoises with emydid turtles and presented data that tortoises lay fewer but larger eggs compared to emydids. While both groups allocate about the same reproductive effort on an annual basis, the allocation pattern is quite different. He pointed out that the kinesis of the posterior marginal shell and the neutral pH of the stomach were important adaptations for hatchlings. Recruitment of neonates may be very infrequent in natural populations and this emphasizes the need for long-term studies of 20–30 years (a rare event among ecological studies in general and difficult with academic lifestyles). The nutritional needs of neonates may be substantially greater than predicted for their body mass. Morafka proposed a chaotic model of recruitment and contrasted the two tortoises from mesic conditions (*G. berlandieri* and *polyphemus*) with the two species from desert conditions (*G. agassizii* and *flavomarginatus*). He pointed out that the larger egg sizes and their heavy lipid stores per year, not their total reproductive effort, make tortoises appear to have a bet-hedging strategy for desert unpredictability.

Germano presented an analysis of comparative life histories among the four species of *Gopherus*. He noted that many details were lacking to provide a fuller understanding of the demography and population dynamics. The four North American tortoise species range widely in size as adults, occur in subtropical or desert environments, and exhibit a sexual dimorphism that is inversely correlated with size. Despite this, the largest and smallest species mature at about the same age. Germano pointed out the need for parallel studies on the Sonoran and Sinaloan populations of *G. agassizii* and on *G. berlandieri* in México to complement previous and on-going studies. Techniques for locating animals by radiotelemetry, determining clutch frequency from radiography and ultrasound, and aging animals from scute sections are some of the procedures that need to be more widely used. The greatest challenge lies in determining longevity of populations. These data are unlikely to become available quickly as the longevity of individual tortoises exceeds the academic lifespan of most researchers! Tinkle's (1979) call for long term ecological studies remains highly relevant to understanding the ecology and behavior of tortoises.

Germano and Bury conclude with a research critique of the field and a strong call for high quality efforts. This article is an accurate description of herpetologists' and ecologists' knowledge about tortoises and serves as an excellent outline for research possibilities. Several areas of fruitful pursuit will involve the use of sample areas large enough to be consistent with the home range of tortoises for estimating occurrence and density, the validation of line transects through different habitats in estimating tortoise abundance, and accumulating information on what determines habitats with high and low density of tortoises.

Their critique also strongly pleads for greater scientific rigor in the design, analysis, and publication of work on the tortoises. Although there is a substantial "gray literature" on all four species, the problem is particularly acute for the desert tortoise. Since this reviewer has experienced this problem first hand during work at the Desert Tortoise Conservation Center (DTCC) in Las Vegas, it is clear that the gray literature is problematic and may slow progress in understanding tortoise biology and presenting clear conclusions about the status of threatened species to the political and social realms for necessary action. Progress is also impeded when the accuracy and validity of such unreviewed work is assumed by workers, particularly those without ecological backgrounds, even though careful reading indicates basic research and statistical standards have not been met. Bury and Germano commend the Gopher Tortoise Council for acting to reduce their proceedings to a quarterly newsletter. Some authors in this book also indicated which citations were unpublished works. Journal editors need to have clear policies about citing such unreviewed literature and whether manuscript reviewers can reject submitted manuscripts based on unreviewed and unpublished works.

The book in whole presents a needed compilation of ecological studies and reviews on the tortoises. The state of knowledge was contrasted with other groups of reptiles, particularly studies of freshwater turtles which remain the best known turtles. The range of topics makes this publication useful to many herpetologists and will stimulate life history, habitat usage, and physiological adaptation studies of turtles and, more broadly, of reptiles.

Results from a simultaneous project on the desert tortoise at the DTCC in Las Vegas (Spotila et al. 1994) were not incorporated in this volume. However, based on Bury and Germano's proposals for future research and their strong recommendation for careful scientific design, the DTCC project unquestionably serves as a model system. The criteria of careful planning, hypothesis-based research, and close collaboration across several biological disciplines produced a significant advance in our knowledge of the biology of *G. agassizii*, which subsequently appeared in *Herpetological Monographs*. A combination of studies on physiological and behavioral correlates of stress, reproductive cycling and social interactions, microhabitat use of burrows and temperature regulation plus new techniques for sexing juveniles and applied experiments involving barriers show the positive effect of broad collaboration and the significant potential for advances in knowledge when integrating scientific perspectives with management goals.

The absence of reference to this significant work in Bury and Germano's book, however, simply indicates that progress is be-

ing made on a wide ranging basis for four species which are currently or potentially threatened by human activity. As *Biology of North American Tortoises* is free from the U.S. Fish and Wildlife Service, it should be widely available to the herpetological community. It provides a good review of issues and the published literature for those not deeply involved in tortoise work, suggests many project possibilities for graduate students, and challenges herpetologists in the area to focus on high quality work. The success of this book will be measured by how quickly R. B. Bury plans a third compilation.

Animal welfare concerns have, in the last few years, become priority items for zoological parks and research institutions. Until very recently, however, the focus of welfare issues was on mammals and birds; reptiles were largely ignored.

The present volume is one of a few current publications that deals exclusively with the well-being of reptiles. The book is divided into eleven chapters, with the first half addressing biological issues, and the second half dealing with ethological topics. An array of zoologists, ethologists, and veterinarians contributed to the text, resulting in a comprehensive, thought-provoking document.

The first two chapters, Physiology and Functional Anatomy (Harvey B. Lillywhite and Robert E. Gatten, Jr.) and Biology of Stress...(Louis J. Guillette, Jr., Alison Cree, and Andrew A. Rooney) contain pertinent, if somewhat technical, structural and physiological information. Chapter 2, especially, presents very interesting information concerning the effects of stress on the immune system, growth, and reproduction. Chapter 3, Nutritional Considerations (Fredric L. Frye), while presenting valid information, tends to be wordy and over-emphasizes some topics (i.e., accidental herbivores and omnivores). Chapter 4, Veterinary Perspectives (John E. Cooper and David L. Williams), contains excellent sections on anesthesia and evaluation of relative stressors; it explains major concepts in sufficient detail to be useful to all readers. The argument on "pseudonatural" versus "clinical housing" is also presented in a very objective fashion. The final chapter in the biology section, Naturalistic Versus Clinical Environments (Clifford Warwick and Catrina Steedman), is somewhat disappointing. The opinion is presented that environments which are "too clean" cause immune suppression, without addressing other concomitant husbandry stressors. Additionally, "sanitation" and "sterilization" are used almost interchangeably, when these in fact are two distinct concepts. This weakens the chapter and leads the reader to erroneously conclude that thorough environmental cleaning is always detrimental to the reptile's health and well-being.

The second half of the book deals with ethological aspects of captive reptile well-being. Chapters 6, Normal Behavior (James C. Gillingham) and 7, Effects of Ontogenetic Processes and Rearing Conditions (Gordon M. Burghardt and Donna Layne), are extremely well written. They are succinct and provide appropriate specific information for each major topic covered. The discussion of neonatal "social arrangements" and feeding were particularly interesting. Both sections are also well-referenced.

Chapter 8, Behavioral Consequences of Husbandry Manipulations... (David Chiszar, W. Thomas Tomlinson, Hobart M. Smith, James B. Murphy, and Charles W. Radcliffe), presents objective views and data on effects of handling and cleaning; it also offers a reasonable compromise between sanitation and the reptile's well-being (i.e., leaving olfactory cues in a cleaned cage).

Chapter 9, Psychological and Behavioral Principles and Problems (Clifford Warwick), contains some very useful lists of signs of psychological comfort and psychological arousal. However, the tone of this section is often caustic and condescending, making it difficult for the reader to appreciate the strengths of this chapter.

Chapter 10, Ethologically Informed Design in Husbandry and Research (Neil Greenberg), presents a philosophical, realistic viewpoint on developing appropriate research designs. Finally, Miscellaneous Factors Affecting Health and Welfare, Chapter 11 (Phillip C. Arena and Clifford Warwick), deals with stress and pain, euthanasia, and reintroduction.

As a whole, the book is very informative and fascinating to read. The most detracting aspect of this volume is the negative tone displayed in Chapters 1, 5, 9, and 11. Many of the attitudes and practices described as commonplace today are actually holdovers from years past. Most researchers, curators, and animal care and use committees are very interested in captive reptile welfare and want to learn appropriate husbandry, handling, and project design. Condescension as expressed here is likely to discourage, if not offend, these individuals. Chapters 4, 6, 7, 8, and 10 present a much more positive and encouraging attitude, especially regarding collaboration among professionals to achieve appropriate standards of care. Overall, the book is a very useful text and one that should be included in the library of all herpetologists, zookeepers, researchers, research veterinarians, and animal care and use committees.

ERRATUM

Stephen Hager's Natural History Note (1995. Herpetol. Rev. 26:145–146) concerning growth in *Phrynosoma coronatum* contained several printing errors. Sample sizes for both adults and hatchlings were 4 (not 8 and 5 as printed). The standard deviation for hatchlings should read SD = 0.133; and for adults, SD = 0.169.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Techniques, Natural History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles or Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Natural History Notes or Geographic Distribution manuscripts; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, New Jersey Field Office, The Nature Conservancy, 200 Pottersville Road, Chester, New Jersey 07930, USA (tel. 908-879-7262; fax 908-879-2172).

Herpetological Review is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Karen Toepfer, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 600		$300
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 600	$150

For back orders only: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA (fax 314-977-3658).

Results of the recent SSAR election are as follows:

President-elect (to serve as President for 1997): ..... *Henry R. Mushinsky.*

Secretary: ..... *Ellen J. Censky* (unopposed).

Treasurer: ..... *Karen L. Toepfer* (unopposed).

Directors: ..... *John B. Iverson, James P. Bogart.*

SSAR Student Travel Awards Fundraiser Call For Donations

At the 1995 SSAR meeting in Boone, North Carolina, the SSAR Student Travel Awards Committee introduced its second annual Frameable Art Silent Auction to raise funds for students attending and presenting papers at the 1996 meeting in Lawrence. The outcome of this year's silent auction was especially positive, with over $1700 raised. On behalf of SSAR and the Student Travel Awards Chair, Dawn Wilson, thanks to all who participated. Hoping to continue this successful tradition, the Student Travel Awards Committee is pleased to announce the third annual frameable art silent auction to be held at the 1996 SSAR meeting in Lawrence. Acceptable donations include: photos of your study animal (or herpetologists!), line drawings, prints, paintings, or anything that can be put into a frame, if not framed already. If you are interested in donating an item please contact: *John Lee, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA; Tel. 803-725-5873; e-mail: LEE@SREL.EDU.*

SSAR Student Travel Awards Call for Applications

Ten SSAR Student Travel Awards of $200 each are available to undergraduate and graduate student members of SSAR to help defray the cost of travel to the upcoming meeting in Lawrence.

An applicant must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author of a paper or poster to be presented. An applicant must include in the application package:

1) a letter signed by his/her major advisor or departmental chair that states: he/she is currently an undergraduate or graduate student and that he/she is not completely funded for travel from another source;

2) an official copy of the poster or paper abstract to be presented;

3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Travel Awards Committee are excluded from applying for a travel award.

APPLICATIONS MUST BE POSTMARKED BY 15 MAY 1996. Award recipients will be notified by early June 1996 and award checks will be dispersed at the meeting. Send applications to: *John Lee, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA; Tel. 803-725-5873; e-mail: LEE@SREL.EDU.*

About Our Cover

Sauromalus hispidus is one of four endemic species of chuckwalla lizards found on islands in the Gulf of California, México; the others are *S. klauberi, S. slevini*, and *S. varius* (Hollingsworth 1995. M.A. thesis, San Diego State University). Each of the latter three species is restricted to a single island, but *S. hispidus* occurs on 11 islands throughout the Isla de la Guarda archipelago, the Isla San Lorenza group, and numerous small islands within the Bahía de Los Ángeles (Grismer, Beaman, and Lawler 1995. Cat. Amer. Amphib. Rept. 615:1–4). Its occurrence on relatively widely distributed islands of varying ages and geological origins (Grismer 1994. Herpetol. Nat. Hist. 2:17–40) has led to speculation that much of its distribution is the result of aboriginal introductions as a food source (Aschmann 1959. The Central Desert of Baja California, Demography and Ecology. Manessier Publ. Co., Riverside, California; Case 1982. *In* G. M. Burghardt and A. S. Rand (eds.), Iguanas of the World: Their Behavior, Ecology, and Conservation, pp. 184–212. Noyes Publ., Park Ridge, New Jersey).

Much of our knowledge of the life history and ecology of *Sauromalus hispidus* comes from the work of Case (1982, *op. cit.*; 1983. *In* T. J. Case and M. L. Cody (eds.), Island Biogeography in the Sea of Cortez, pp. 159–209. Univ. California Press, Berkeley). This species is rather widespread on the islands in the Gulf, although it prefers rocky areas where adults take refuge in self-constructed burrows at the base of rocks. Individuals are commonly observed feeding on vegetation growing in nearby arroyo bottoms and groups of 8–10 can be seen feeding at a single site. Juveniles have been observed up to 3 m above ground feeding on the fresh blossoms of palo verde trees.

One of the most striking features of *Sauromalus hispidus* and *S. varius* is their very large adult size, with snout-vent lengths reaching 317 mm in the former (Case 1982, *op. cit.*; Hollingsworth, *op. cit.*). Case considered these species to be examples of insular gigantism, resulting from a seasonally abundant food supply and the absence of predators. Conversely, Grismer et al. (*op. cit.*) postulated that large body size was primitive for *Sauromalus* and that small body size was the evolutionarily derived condition (i.e., chuckwallas went from big to small). This is supported by additional phylogenetic, morphological, and behavioral correlates presented by Hollingsworth (*op. cit.*).

Unfortunately, like other endemic Gulf-island reptiles, *Sauromalus hispidus* is beginning to appear in the illegal pet trade (Mellink 1994. Herpetol. Nat. Hist. 3:95–99). The impressive size and generally docile nature of these lizards makes them attractive pets, and their ease of collection makes them simple targets for reptile smugglers in Baja California.

The cover photo was taken by **L. Lee Grismer**, associate professor of biology at La Sierra University in Riverside, California. Lee's research on the systematics and biogeography of the amphibians and reptiles of Baja California has spanned nearly 20 years and resulted in over 40 publications. His just-completed book (*Amphibians and Reptiles of Baja California and the Sea of Cortes: A Guide to their Identification, Distribution, and Natural History*) will be published by the University of Arizona Press. Grismer's photo (using a Nikon N90S camera and 17mm wide angle lens with Kodachrome 64 film) was taken from the crest of the southern end of Isla San Lorenzo Sur overlooking the Gulf of California and the adjacent peninsula of Baja California.

Separation and imaging of Grismer's photo is the work of **Jim Bridges** of Herpeto Inc., Hollywood, Florida, USA.

Items Needed for SSAR Auction

Joe Collins will be conducting the SSAR auction during the annual meeting at the University of Kansas in July 1996. All proceeds from the auction go to the SSAR treasury, and help to continue the production of diverse publications and services which has made the SSAR the largest professional herpetological society in the world. Items of value as well as those that lend themselves to humor are always welcome. Joe is skilled at removing large quantities of cash from auction participants through the judicious use of beer and plastic. Anyone wishing to donate auction items in advance should send them directly to: *Joseph T. Collins, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454 USA.*

New SSAR Conservation Committee Page on WWW

The Conservation Committee has prepared a page of links to major conservation interest-groups, both herpetological and general. Rather than duplicating (or plagiarizing!) the work of others, we have attempted to link readers to pages that, in turn, provide often extensive directories of conservation sites and of available LISTSERVs.

The page was initiated at the urging of SSAR Conservation Committee Chair C. Kenneth Dodd, Jr. (e-mail: kdodd@nervm.nerdc.ufl.edu) as a general resource for the herpetological community. It was compiled by George Pisani (e-mail: gpisani@falcon.cc.ukans.edu) and Breck Bartholomew (e-mail: Herpbooks@sisna.com) using WAIS searches on a variety of topics. We do not represent this list as being all-inclusive, and welcome suggestions from readers for additions or deletions.

To access the page, use the CONSERVATION button on the SSAR home page (http://falcon.cc.ukans.edu/~gpisani/SSAR.html).

NEWSNOTES

Roger Conant Honored

On 15 July 1995, Roger Conant received the Nature Educator of the Year Award of the Roger Tory Peterson Institute of Natural History in Jamestown, New York. The presentation was made by the dean of birders himself, Roger Tory Peterson, at the institution founded in his hometown. The award is given annually to a person of national importance whose lifework has influenced young people in a manner consistent with the mission of the Institute: to inform society about the natural world through the study and teaching of natural history.

On 1 June 1996, Conant will receive the David S. Ingalls, Jr. Award for Excellence from the Cleveland Museum of Natural History. This award honors a person who has excelled in research, conservation, or education in a discipline of natural science represented in the Museum's collections. The individual chosen must have made a major contribution that is recognized by the national and international scientific communities. The previous winners of the Ingalls award are Stephen Jay Gould (1993), Roger Tory Peterson (1994), and Edward O. Wilson (1995). The award ceremony will be open to the public. For details please contact the Museum (Tel. 216-231-4600) or the Northern Ohio Association of Herpetologists (Tel. 216-254-3006).

WANTED
COLOR SLIDES OF HERPS FOR WEST INDIES BOOK

A COLOR FIELD GUIDE TO THE 632 SPECIES OF AMPHIBIANS and reptiles in the West Indies is "in progress" and will be published by SSAR (probably in 1997 or 1998). All profits from the sale of the book will go to the society. Color slides of about 500 species have been taken, and some additional species will be photographed during the next year. However, it is hoped that slides of some of the "missing species" can be obtained by generous loans from colleagues. Below is a list of the species for which slides are needed.

If you have slides of one or more of the species listed below, please contact the author, Blair Hedges, at sbh1@psuvm.psu.edu (tel. 814–865–9991; fax 814–865–9131; Department of Biology, 208 Mueller Lab, Penn State University, University Park, PA 16802). An indication of the quality of the image would be helpful. For the non-endemic West Indian species, mainland specimens are fine. White backgrounds are preferred, and for anoline lizards, closeups of head with extended dewlap are needed in addition to full body shots; but any publishable photograph is welcome. After information on slide availability is assembled, slides will be requested in early 1997. Unfortunately, no funds are available for the purchase of slides, but loan of needed slides (for one-time use) will be much appreciated and will be properly acknowledged in the book.

Color slides are needed for the following species:

AMPHIBIANS—*Bufo cataulaciceps, B. fluviaticus, B. fractus, B. lemur, Eleutherodactylus jasperi, E. karlschmidti, E. lentus, E. lucioi, E. semipalmatus, E. thomasi, E. warreni, Leptodactylus insularum, L. validus.*

REPTILES—*Trachemys decorata, T. decussata, T. stejnegeri, T. terrapen, Amphisbaena fenestrata, Cadea palirostrata, Celestus anelpistus, C. curtissi, C. duquesneyi, C. fowleri, C. hewardi, C. macrotus, C. microblepharis, C. occiduus, Diploglossus montisserrati, Aristelliger cochranae* (Navasa Island endemic), *A. georgeensis, A. hechti, Hemidactylus garnotii, H. palaichthus, Phyllodactylus pulcher, Sphaerodactylus argivus, S. beattyi, S. becki, S. caicosensis, S. cochranae, S. elasmorhynchus, S. kirbyi, S. lazelli, S. levinsi, S. mariguanae, S. microlepis, S. micropithecus, S. nycteropus, S. ocoae, S. parthenopion, S. scaber, S. shrevei, S. underwoodi, S. vincenti, S. williamsi, Thecadactylus rapicauda, Bachia heteropus, Gymnophthalmus pleii, Cyclura carinata, C. cychlura, C. pinguis, Anolis acutus, A. aeneus, A. altavelensis, A. alumina, A. birama, A. concolor, A. cyanopleurus, A. delafuentei, A. desechensis, A. ernestwilliamsi, A. extremus, A. fairchildi, A. ferreus, A. fugitivus, A. griseus, A. juangundlachi, A. koopmani, A. longiceps, A. longitibialis, A. luciae, A. marcanoi, A. marmoratus, A. mimus, A. monensis, A. nubilis, A. oculatus, A. paternus, A. pigmaequestris, A. pinchoti, A. richardi, A. rimarum, A. roosevelti, A. roquet, A. rubribarbus, A. rupinae, A. spectrum, A. vanidicus, A. vescus, A. websteri, Ameiva ameiva, A. cineracea, A. dorsalis, A. corvina, A. dorsalis, A. fuscata, A. major, A. polops, Cnemidophorus vanzoi, Kentropyx borckiana, Tretioscincus bifasciatus, Leiocephalus endomychus, L. eremitus, L. herminieri, L. onaneyi, L. pratensis, L. psammodromus, L. rhutidira, L. vinculum, Epicrates chrysogaster, E. exsul, E. gracilis, E. subflavus, Alsophis anomalus, A. rufiventris, A. sanctaecrucis, Arrhyton ainictum, A. polylepis, Chironius vincenti, Clelia erabunda, Coniophanes andresensis, Ialtris agyrtes, I. parishi, Liophis cursor, L. melanotus, L. ornatus, L. perfuscus, Mastigodryas bruesi, Pseudoboa neuwiedi, Leptotyphlops bilineata, L. calypso, L. goudoti, L. tenella, Tropidophis caymanensis, T. greenwayi, T. nigroventris, T. semicinctus, Typhlops catapontus, T. caymanensis, T. epactia, T. gonavensis, T. monensis, T. tasymicrus, T. tetrathyreus, Bothrops caribbaea, B. lanceolata.*

ASIH Symposium Announcement

"Comparisons and Current Uses of Phylogenetic Approaches to Ichthyology and Herpetology" is the tentative title of a symposium to be held at the 77th Annual Meeting of the American Society of Ichthyologists and Herpetologists 25 June–2 July 1997 in Seattle. The co-chairs are Mark Pyron and Robert Espinoza.

It is becoming increasingly evident that incorporating phylogenetically-based methods can be important to studies addressing questions germane to comparative biologists. These methods have also served to reunite diverging fields by providing an important link between evolution and morphology, physiology, behavior, and ecology. Numerous phylogenetic approaches are now available to comparative biologists. However, it is not always apparent which approach is the most appropriate for a given study. Furthermore, debate continues to erupt on the theoretical, statistical, and practical soundness of many of the currently used techniques.

This symposium will address these issues by drawing on both theoretical and empirical studies from the fields of ichthyology and herpetology. We anticipate that the diversity of speakers and topics presented will promote a critical evaluation of the merits and limitations of comparative methods in current use.

If you have any questions regarding the symposium, contact MP for fishes (pyron@uiuc.edu) or RE for herps. *Robert E. Espinoza, Department of Biology, University of Nevada, Reno, Nevada 89557-0015, USA. Tel. (702) 784-4565; Fax (702) 784-1369; e-mail: espin_r@unr.edu.*

MEETINGS

Third World Congress of Herpetology

The Third World Congress of Herpetology will be held on 2–10 August 1997 in Prague, Czech Republic, hosted by the Academy of Sciences of the Czech Republic and the Czech Herpetological Society. The country, known by its amphibians of the Carboniferous and Permian ages, some of them related to the oldest reptiles, others close to the ancestors of frogs, and by the Tertiary anurans with their astonishingly well-preserved tadpoles, is in the center of Europe. Thus, the place is easily accessible from all parts of the World. This, together with low costs for high quality convention facilities (the Czech Republic is among the fast developing post-communist countries successfully transforming its economy) is why we expect that the individual costs will be kept at a very low level. Moreover, organizers want to encourage student participation by a reduced student rate. Attendance is expected to be large (at least 1300 delegates).

The program of the Congress will cover all fields of herpetology, both contemporary taxa and fossils, and emphasize an interdisciplinary approach. All scientific activities presented to the Congress will be defined as scientific problems, not as methods. The Congress should provide a platform for meetings and discussions of neo- and paleoherpetologists and, as a consequence, help to remove the border which still exists here and there between the people interested in contemporary and extinct amphibians and reptiles.

The organizers' intention is to prepare the Congress in agreement with the original aim of such scientific meetings which was to enable people to present their own results and to expose these results to immediate verbal discussion. Consequently, the main part of the Congress will be filled with contributed talks arranged in monotopic symposia. Additionally, there will be some specialized symposia and round tables organized in advance by those people who want to promote discussions on certain topics. There also will be two poster exhibitions with 400 posters each. Also the posters will be grouped by topic. To accommodate the expected number of contributions, it is expected that the program will run in ten concurrent sections, in halls with capacities from 50 to 300 seats. This will provide for 720 talks, each 20 minutes long. The Congress will begin and conclude with six (3 + 3) plenary lectures. Innovative, provocative, non-conforming, and hence stimulating research are the criteria for the selection of these speakers. Proposals should be submitted to the Congress Director (see below) who will transmit them to the Scientific Programme Committee.

The Congress will feature both scientific and social events. There will be evening programs including a concert of old Czech music, a beer party in a brewery dating back to 1499, and a steamer cruise on the Vltava River. The Congress program will be divided by one-day professional field excursions. Several itineraries will be prepared, to meet interests of both neo- and

Some of Prague's street signs are associated with herpetology. During the 14th century there was a lot of building in Prague, and the labeling of houses became absolutely indispensable. These plaques were so important that the house owners got their nicknames after them—"Janek from the Golden Snake" or "Simon from the Green Frog." They were used until 1770, when, in spite of protests by Prague councillors, the houses were given numbers.

paleoherpetologists. Notable are the large areas that have served from the 18th century until 1991 (when the Soviet army left the country) for military exercises (the largest tank shooting range in Europe). As these areas were not affected by agriculture during the past 200 years, the ecosystem evolved there only by natural succession. This has resulted in surprisingly high population densities of amphibians and reptiles.

Prague is one of those rare cities whose more than thousand-year history is preserved in its architecture and beautiful scenery, which is why it was included in the World Heritage List. The appointed CBT Travel Agency prepared a wide variety of half-day and full-day tours for accompanying persons, to present the rich historic background, folklore, and cultural treasures, not only in Prague but in the whole country. The post-Congress tours will include a nine-day excursion to Central Asia, which will provide opportunities to see historical sites and to watch splendid animals. Another tour ("Paleo-herps of Central Europe") will cover shorter distances but allow in-depth examination of the history of amphibians and reptiles. Participants will see, among others, ichthyosaur embryos, plesiosaurs, crocodiles, pterosaurs, and many other Mesozoic reptiles (also several *Archaeopteryx* specimens) in the most famous museum exhibitions in Bavaria.

There will be also some other activities associated with the Congress, for instance the exhibition "Evolution of Central European Herpetofauna" in the National Museum, 6th International Symposium on Pathology of Reptiles and Amphibians organized by the University of Veterinary and Pharmaceutical Sciences in Brno, exhibition and sale of scientific books by publishing houses and antiquarian bookdealers from all around the world.

During September 1995, the First Announcement and Preliminary Registration Form were distributed. For those wishing to receive this material, please send your request to either of the persons listed below. To determine if you are already on the WCH mailing list, check the Congress World Wide Web page (www.gli.cas.cz) or their mail server (wch-source@gli.cas.cz). On these Internet addresses, one may also find names of persons already registered. During June and July 1996, the Call for Papers and Registration Form will be distributed, but only to respondees to the First Announcement. *The deadline for receipt of abstracts will be 1 January 1997.* Presenters and their titles will be listed on the Internet after January 1997. For those who want to see Congress Abstracts in advance, these will be available on 3.5-inch diskettes by the end of March 1997.

Arrangements for the Third Congress of Herpetology are well advanced. However, the Congress cannot be successful without participants. Only they will fill it with an interesting and attractive program. So keep in mind that there are some enthusiasts in Prague prepared to do all they can to make your visit to Prague a wonderful experience.

Contacts.—For scientific aspects (program, abstracts, professional field excursions, collecting permits): Zbynek Rocek, Congress Director, Department of Paleontology, Geological Institute, Academy of Sciences, Rozvojová 135, 165 00 Praha 6 - Suchdol, Czech Republic. Tel. (++42-2) 24311421; Fax (++42-2) 24311578; e-mail: rocek@gli.cas.cz.

For technical aspects (registration fees, transportation, accommodation, accompanying persons program, post-Congress tours, conditions for trading activities, general inquiries, tours and excursions): Third World Congress of Herpetology, c/o Czech Medical Association J.E. Purkyne, Congress Department, P.O. Box 88, Sokolská 31, 120 26 Praha 2, Czech Republic. Tel. (++42-2) 296889 or (++42-2) 249151195; Fax (++42-2) 294610 or (++42-2) 24216836.

Prepared by Zbynek Rocek

Meetings Calendar

20–23 March 1996—Society for Northwestern Vertebrate Biology Annual Meeting, LaSells Stewart Conference Center, Corvallis, Oregon, USA. The meeting will include a one-day training workshop on amphibians and reptiles of the Pacific Northwest, a monitoring symposium, sessions on herpetology, mammalogy, and ornithology, and a live animal display of herps of the PNW. For additional information contact Janet Jones, Treasurer, SNVB, 4820 Yelm Hwy SE, Suite B-175, Olympia, Washington 98503, USA. Tel. (360) 753-7663.

12–14 April 1996—Minton Symposium, Indiana Academy of Sciences, Indiana University/Purdue University Conference Center, Indianapolis, Indiana, USA. *Refer to meeting announcement on page 6 for details.*

13 April 1996—All Florida Herpetology Conference, University of Florida, Gainesville, USA. *Refer to meeting announcement on page 6 for details.*

8 June 1996—Northeast Turtles Conference, Lyndhurst, New Jersey, USA. Sponsored by the New York Turtle and Tortoise Society. Tentative date. To obtain confirmation or further details, contact NYTTS at (212) 459-4803 or monitor sci.bio.herp on the Internet for details.

13–19 June 1996—76th Annual Meeting, American Society of Ichthyologists and Herpetologists, together with the 44th Annual Meeting of The Herpetologists' League, New Orleans, Louisiana, USA. Hosted by the University of New Orleans. Deadline for receipt of abstracts 1 April 1996. Contact: Bob Cashner, ASIH

Local Committee Chair, Dept. Biological Sciences, University of New Orleans, New Orleans, Louisiana 70148, USA. Tel. (504) 286-6741; Fax (504) 286-6121; e-mail RCCBS@UNO.EDU.

19–23 June 1996—Annual Meeting, The Society for the Study of Evolution and Society of Systematic Biologists.Washington University, St. Louis, Missouri, USA. SSB Symposium: "Morphological Data in Phylogenetic Analysis: Recent Progress and Unresolved Problems" (John Wiens, Organizer). Contact: Michael Ryan, Department of Zoology, University of Texas, Austin, Texas 78712, USA. Tel. (512) 471-5078. Meeting Web page at http://bio650.wustl.edu.

27–29 June 1996—20th Anniversary Meeting, International Herpetological Symposium. Sheraton Fiesta Hotel, San Antonio, Texas, USA. Focus on the herpetofauna of Madagascar and vicinity. Keynote speaker: W. Ronald Heyer. Banquet speaker: William W. Lamar. Contact: Davis Hulmes, 361 Van Winkle Avenue, Hawthorne, New Jersey 07506, USA. Tel. (201) 427-0768.

24–29 July 1996—39th Annual Meeting, Society for the Study of Amphibians and Reptiles. Hosted by The University of Kansas, Lawrence, Kansas, USA. *Refer to meeting announcement in this issue for details.*

1–5 August 1996—2nd International Conference on the Biology and Conservation of the South Asian Amphibians and Reptiles, University of Peradeniya, Sri Lanka. Contact: Anslem de Silva, Conference Director, Faculty of Medicine, University of Peradeniya, Sri Lanka. Tel. 94-08-88130; Fax 94-08-32572; e-mail: Anslem@Med.Pdn.ac.lk.

20–24 August 1996—2nd International Symposium and World Congress on the Preservation and Conservation of Natural Science Collections: "Natural Science Collections—A Resource for the Future." St. John's College, Cambridge, U.K. Contact: Chris Collins, Natural Sciences Congress '96, Geological Conservation Unit, Department of Earth Sciences, Downing Street, Cambridge, CB 2 3EQ, U.K. Tel. (0223) 62522; fax (0223) 60779.

24–27 August 1996—3rd Annual Conference of the Association of Reptilian and Amphibian Veterinarians, Saddlebrook Resort, Tampa, Florida, USA. Deadline for receipt of abstracts 15 April 1996. Contact: Wilbur Amand, VMD, P.O. Box 605, 1 Smithbridge Road, Chester Heights, Pennsylvania 19017, USA. Fax (215) 387-2165.

19th Annual AFHC

The All Florida Herpetology Conference will be held Saturday, 13 April 1996 at the University of Florida in Gainesville. The Florida Museum of Natural History and Gainesville Herpetological Society co-sponsor the event. Speakers include Al Baldago, Winston Card, Ellen Censky, Indraneil Das, James Dixon, Walter Meshaka, Tom Tyning, and Wayne Van Devender. Other events include a "Seminar in Current Gopher Tortoise Conservation Issues," with speakers Mike Allen, Ray Ashton, Joan Berish, Dick Franz, Grace McLaughlin, and Henry Mushinsky; a reptile egg incubation workshop led by Bill Brant and Eugene Bessette; and a disease diagnostics laboratory conducted by Richard Funk. A live exhibit of Florida herpetofauna is planned, along with a close-up photography workshop. Field trips to the Katherine Ordway Preserve and the Perry Oldenburg Mitigation Park will be held Sunday, 14 April. Herpetological art, supplies, and books will be exhibited for sale, and the traditional evening barbecue and auction round out the evening at the museum. To preregister, call or write: *David L. Auth, Division of Herpetology, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA. Tel. (904) 392-1721.*

SYMPOSIUM IN HONOR OF DR. SHERMAN A. MINTON, JR.
12–14 April 1996, Indianapolis, Indiana

The Indiana Academy of Sciences is sponsoring a Symposium in April of 1996 in honor of **Sherman A. Minton, Jr**. on the occasion of the publication of his revision of the *Amphibians and Reptiles of Indiana*. The symposium will be held 12–14 April 1996 in Indianapolis at the Indiana University/Purdue University Conference Center. Dr. Minton is well known for his work on venomous reptiles, the reptiles of Pakistan, the regional herpetology of the Midwest, and popular books on herpetology.

The Symposium will include a Friday evening (12 April) dinner featuring **Whit Gibbons** as the after dinner speaker. The morning program of the Saturday Conference (13 April) will focus on Minton's career with talks by **Carl Gans** (reptiles of Pakistan), **David Hardy** (pitviper bites), **Bernard Bechtel** (abnormalities in reptiles), and **Harold Voris** (venomous sea snakes). The afternoon session will focus on "Hoosier Herpetology" and the publication of Minton's revision of his classic monograph on the herpetofauna of Indiana; biologists working on the amphibians and reptiles of Indiana will present brief overviews of their research and provide a perspective on herpetological research in Indiana today. There will be optional field trips on Sunday (14 April).

For registration information, contact: Harriet A. Rodenberg (Minton Conference), University Place, Conference Center and Hotel, 850 West Michigan Street, Indianapolis, Indiana 46202-5198, USA. Tel. (317) 274-5053; Fax (317) 274-3878; e-mail: hrodenbe@indycms.iupui.edu.

Field Assistant in Arizona

Field Assistant is needed in southeast Arizona 1 July–15 November 1996 for rattlesnake capture-recapture and tissue-sampling study ($1200/mo and worker's compensation coverage). Applicants should be familiar with capture and (museum) preservation techniques for both reptiles and rodents. The successful candidate must be able to readily identify all reptiles and rodents found in SE Arizona upon arrival. A vehicle is required—preferably a small truck or larger. A small camper with bed, stove, and refrigerator is provided.

Long hours and no time off—every day is a work day. NO collecting for personal reasons allowed, on or off site. I need hard workers who will dedicate themselves to the project and to careful and precise collection and recording of data. Send cover letter, two letters of recommendation from biologists, and curriculum vitae or resume to: *Andy Holycross, ASU Zoology Dept., Tempe, Arizona 85287-1501, USA*. 30 April 1996 application deadline. Please direct questions/inquiries by e-mail (holycow@asu.edu) or telephone (602-965-3571).

LETTERS TO THE EDITOR

To Stipple, Not to Stab

YEHUDAH L. WERNER
Department of Evolution, Systematics and Ecology
The Hebrew University of Jerusalem, 91904 Jerusalem, Israel
e-mail: yehudahw@vms.huji.ac.il

Tucker (1995) argues that species-range maps that contain actual locality-record points should not additionally show the hypothetical overall range ("stippling"). His concern is that hasty readers might overlook the author's explanations, and conclude from the map that the species occurs at points where really it is absent; this could lead to erroneously ascribing continuity to some populations which in fact are disjunct and merit conservation.

Tucker's concern is justified and his conclusion on methodology is legitimate, though below I shall beg to differ. Nevertheless, I feel that the way he presented his case calls for certain comments.

(a) Tucker (of the Illinois Natural History Survey) speaks of the field-guide level of literature (tertiary literature) but selects for his example of potentially misleading stippling the 1961 monograph of Smith (of the Illinois Natural History Survey). After 34 years this work may be unknown to many readers. It was decidedly not a field guide; it was a research report and defined as such (primary literature). This changes the target readership and the forecast of abuse of the maps.

(b) Smith (1961) only hatched the overall range, within Illinois, for those species which do not occur throughout the state. He did not hatch the maps of species which he believed to occur state-wide. Thus his map for *Rana catesbeiana* (Fig. 83, p. 97) looks just as Tucker wishes. There are some records in most counties but a two-county-wide latitudinal belt from Rock Island and Mercer to Will and Kankakee counties lacks records. So here Tucker's hasty reader, unless he peruses the text, will walk away not knowing that in the author's opinion this discontinuity was insignificant.

(c) Although Tucker is worried about hasty readers, he himself sets them a trap: his Fig. 1A shows the overall range of *Clonophis kirtlandi* "after Smith, 1961" without locality dots, whereas in fact in the original (Fig. 236, p. 253) these were present. Anybody reading Tucker hastily would gain from his illustration a quite mistaken impression of the work of Smith. It was this figure that triggered my involvement, along with curiousity as to what kind of organism *Clonophis kirtlandi* was.

(d) Speaking of haste, full interpretation of Tucker's note is encumbered by missing references to works mentioned in the text (Johnson 1987; Minton 1972) and a cryptic reference to a "Catalogue of American Amphibians and Reptiles." The introduction of references in the text with "e.g." to say that the author knows of more literature is usually avoided as a matter of course.

(e) Lastly, I contest Tucker's taxonomy of conclusions. He holds that a conclusion on overall range is subjective while subspecific identification of specimens is objective. But surely with a little more work a hypothesis on overall range can be concluded quite objectively, and certainly it is easy (and common) to identify subspecies subjectively.

These comments notwithstanding, Tucker (1995) is right in saying that the style of maps must depend on circumstances and purpose, and hence is wrong in criticizing Smith (1961) and dictating a standard. My colleagues and I have long regarded the Smith (1961) maps as exemplary, as also did Burr and Page (1987). Smith's maps, innovative at the time, distinctly show at a glance both the facts and the author's interpretation. Of course, when hatching is light as in Smith (1961) the situation is clearer than it would be with heavy stippling as in Tucker (1995).

CURRENT RESEARCH

The purpose of **Current Research** is to present basic summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA; e-mail: herpbooks@sisna.com. Comments and suggestions are also welcome.

Population Dynamics

The *Australian Journal of Ecology* recently published a series of papers presented at the Second World Congress of Herpetology, Symposium on Population Dynamics.

SINSCH, U., AND D. SEIDEL. 1995. Dynamics of local and temporal breeding assemblages in a *Bufo calamita* metapopulation. Aust. J. Ecol. 20(3):351–361.

JEHLE, R., W. HODL, AND A. THONKE. 1995. Structure and dynamics of central European amphibian populations: A comparison between *Triturus dobrogicus* (Amphibia, Urodela) and *Pelobates fuscus* (Amphibia, Anura). Aust. J. Ecol. 20(3):362–366.

BELL, B. D., AND A. P. BELL. 1995. Distribution of the introduced Alpine newt *Triturus alpestris* and of native *Triturus* species in north Shropshire, England. Aust. J. Ecol. 20(3):367–375.

TINSLEY, R. C., AND K. TOCQUE. 1995. The population dynamics of a desert anuran, *Scaphiopus couchii*. Aust. J. Ecol. 20(3):376–384.

BERVEN, K. A. 1995. Population regulation in the wood frog, *Rana sylvatica*, from three diverse geographic localities. Aust. J. Ecol. 20(3):385–392.

BULL, C. M. 1995. Population ecology of the sleepy lizard, *Tiliqua rugosa*, at Mt. Mary, South Australia. Aust. J. Ecol. 20(3):393–402.

BRUCE, R. C. 1995. The use of temporary removal sampling in a study of population dynamics of the salamander *Desmognathus monticola*. Aust. J. Ecol. 20(3):403–412.

Tuatara Conservation

Cree et al. compare evidence for successful reproduction of tuatara in the presence or absence of introduced Pacific rats. On two rat-free islands, 22–31% of all tuatara captured were juveniles or small adults, whereas juveniles were not seen on five of the six rat-inhabited islands and small adults were absent from three. Plasma concentrations of sex hormones suggest that at least

some adults of both sexes remain reproductively active on most islands.

CREE, A., C. H. DAUGHERTY, AND J. M. HAY. 1995. Reproduction of a rare New Zealand reptile, the tuatara *Sphenodon punctatus*, on rat-free and rat-inhabited islands. Conserv. Biol. 9(2):373–383.

Pit Vipers in Ecuador

Kuch and Freire recently published a series of papers on the distribution and morphology of some equatorial pit vipers. Two of the papers contain dot-distribution maps for the species in Ecuador.

FREIRE, A. AND U. KUCH. 1994. A note on the geographical distribution of *Bothrops asper* (Garman, 1883) in Ecuador. Snake 26(2):135–139.

KUCH, U. AND A. FREIRE. 1995. Bemerkungen zur geographischen verbreitung und variabilität von Schlegels palmen-lanzenotter, *Bothriechis schlegelii* (Berthold, 1846), in Ecuador (Squamata: Serpentes: Viperidae) [Notes on the geographical distribution and variation of the eyelash palm-viper, *Bothriechis schlegelii* (Berthold, 1846) in Ecuador (Squamata: Serpentes: Viperidae)]. Herpetozoa 8(1/2):49–58.

KUCH, U. AND A. FREIRE. 1995. Notes on morphology, reproduction and medical importance of the poorly known small-eyed lancehead, *Bothrops microphthalmus* Cope, 1876, in Ecuador (Squamata: Serpentes: Viperidae). Herpetozoa 8(1/2):81–83.

North American Trionychid Systematics

Gardner et al. examined trionychid fossils from the Judith River Group as well as extant species of North American trionychids using cladistic methods. Their analysis supports the referral of three fossil species to the new genus *Aspideretoides* and one to *Apalone*.

GARDNER, J. D., A. P. RUSSELL AND D. B. BRINKMAN. 1995. Systematics and taxonomy of soft-shelled turtles (Family Trionychidae) from the Judith River Group (mid-Campanian) of North America. Can. J. Earth Sci. 32:631–643.

Liverwort on a Lizard

Gradstein and Equihua discuss the presence of three species of algae and a liverwort growing on the head of a lizard. According to the authors, the epizoic liverwort reported constitutes the first record of a cormophytic plant growing on a living vertebrate.

GRADSTEIN, S. R., AND C. EQUIHUA. 1995. An epizoic bryophyte and algae growing on the lizard *Corythophanes cristatus* in Mexican rain forest. Biotropica 27(2):265–268.

Parareptile Phylogeny

The bizarre specializations of turtles have long hindered attempts to establish their relationships with other tetrapods. Recent advances using cladistic methodology, however, have narrowed the possible hypotheses. Lee presents a phylogenetic analysis of the problem in a recent paper. Turtles are first shown to be highly modified survivors of an early radiation of poorly-known amniotes commonly termed "parareptiles." This clade is then subjected to a detailed phylogenetic analysis. The choice of traits used in previous cladistic analyses is also discussed.

LEE, M. S. Y. 1995. Historical burden in systematics and the interrelationships of 'parareptiles.' Biol. Rev. 70(3):459–547.

Evolution of Body Size

Among species of *Varanus*, body mass varies by a full five orders of magnitude making this genus ideal for studying the evolution of body size. Pianka plotted the body sizes of extant varanid species on a phylogeny, and probable sizes at ancestral nodes inferred from those of their descendants. Felsenstein's method of phylogenetically independent contrasts, coupled with information on branch lengths, was exploited to identify several likely instances of relatively rapid evolution of body size both, within and between clades.

PIANKA, E. R. 1995. Evolution of body size: Varanid lizards as a model system. Am. Nat. 146(3):398–414.

Prehensile Anuran Tongue

High-speed videography and muscle denervation experiments were used to quantify the feeding kinematics of the African pig-nosed frog. The tongue of this frog "telescopes" straight out, as opposed to "flipping" as in most other frogs. In addition, two lateral lobes of tissue at the tongue tip envelop prey upon contact. These lateral lobes are capable of applying significant pulling forces and the tongue is described as prehensile. The trajectory of the tongue can be adjusted throughout protraction so that the frog can "aim" its tongue in all three directions. The authors propose that the frog uses a hydraulic mechanism to protract its tongue.

RITTER, D., AND K. NISHIKAWA. 1995. The kinematics and mechanism of prey capture in the African pig-nosed frog (*Hemisus marmoratum*): description of a radically divergent anuran tongue. J. Exp. Biol. 198:2025–2040.

Evolution of Viviparity

Shine tests the idea that prolonged uterine retention directly enhances hatchling viability, because eggs incubated at maternal body temperatures produce "better" hatchlings than do eggs incubated at normal nest temperatures. Eggs of two species of montane scincid lizards were incubated under thermal regimes designed to simulate temperatures in nests and maternal oviducts. Hatchling phenotypes (morphology, running speed, and behavior) were substantially affected by incubation temperatures.

CITATIONS FOR THE ORIGINAL DESCRIPTIONS OF NORTH AMERICAN AMPHIBIANS AND REPTILES

Ellin Beltz

This detailed work is a compilation of the original descriptions of all currently recognized genera, species, and races of amphibians and reptiles found in the United States and Canada. A must for anyone interested in North American herpetology, and a quick, modern reference to when and where a taxon was described. Taxa are arranged alphabetically; brief introduction and literature cited. iv + 44 pages. ISBN 0–916984–36–2. 1995.

Prepublication price $4.00 for SSAR Members After June 30, 1996 $7.00

Orders may be sent to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103 USA
(Include $1.00 for the first copy, and $0.50 for each additional copy to cover handling and postage)

ARTICLES

Notes and Corrections on Two Scolecophidians: *Ramphotyphlops albiceps* and *Leptotyphlops brasiliensis*

V. WALLACH
Center for Vertebrate Studies, Department of Biology
Northeastern University, Boston, Massachusetts 02115, USA

In a discussion of characters that distinguish the snake genera *Ramphotyphlops* and *Typhlops*, I suggested that *Ramphotyphlops albiceps* might be more correctly considered a *Typhlops* due to the apparent lack of the characteristic *Ramphotyphlops*-like hemipenis (Wallach 1993). Of the six specimens available to me at that time, only a single juvenile appeared to be a male upon dissection. I mistakenly took the undeveloped gonads to be testes (no follicles were visible) and the hollow, striated cloacal glands to be straight *Typhlops*-like hemipenes. Examination of a genuine male (ZMUC R52204 from Similan Island, Thailand) demonstrates my error and confirms that *Ramphotyphlops albiceps* was correctly transferred from *Typhlops* to *Ramphotyphlops* by Hahn (1980). The 136 mm male has 20 midbody scale rows, 307 middorsals, 17 subcaudals, and a 6 mm tail. Relative tail length is 4.4% total length as compared with a mean of 1.6% in seven females (range = 1.3–2.0%). Both coiled hemipenes and retrocloacal sacs are present. The hemipenis exhibits 3.5 coils in the retracted state and the retrocloacal sacs are tapered, 0.25 mm in diameter, and 2.5 mm in length (= 2% SVL).

Rodrigues and Puorto (1994) recently described what they believed was the second known specimen of *Leptotyphlops brasiliensis* (IB 50.436) from Barreiras, Bahia, Brazil. They mentioned in passing a specimen cited by Peters and Orejas-Miranda (1970) from Barrieras (= Barreiras), Bahia, Brazil, but discounted its validity by stating that it had been "ignored in the subsequent literature." Orejas-Miranda (1967) purported the species to be known solely from the holotype and Vanzolini et al. (1980) doubted the report of *L. brasiliensis* by Cordeiro and Hoge (1974), which Rodrigues and Puorto (1994) showed to be a misidentified *L. albifrons*. However, the Peters and Orejas-Miranda (1970) record was based on an actual specimen, one that was further documented by Lang (1990), and constitutes the second valid record of *L. brasiliensis*. The specimen described by Rodrigues and Puorto therefore represents the third known specimen of the species.

The second known specimen was collected by J. R. Bailey and A. L. de Carvalho on 21 March 1942 at Barreiras, Bahia, Brazil. It is deposited in the Museum of Zoology at the University of Michigan (UMMZ 108817). I examined the specimen in 1988 and can provide the following data from my brief notes: it is a female with tan dorsum and cream venter; total length 272 mm; midbody diameter 5.5 mm; body diameter contained in total length 46.2 times; snout-vent length 254 mm; tail length 18 mm; tail/total length = 6.6%; 14 longitudinal scale rows; 10 midtail scale rows; 211 total middorsals; 15 subcaudals; three supralabials (two preocular and one postocular); prefrontal, frontal and interparietal small and not broader than long; supraoculars absent; both parietals and occipitals transversely enlarged.

The visceral topography can be described as follows (% = % SVL, MP = midpoint): trachea (19.7%, MP = 10.6%) containing about 150 rings (or 76/10% SVL) with moderate tracheal membrane expansion (TM/CR = 0.25 at midneck, 0.50 posteriorly); left lung complex absent; tracheal entry terminal; right lung unicameral and long (37.4%, MP = 39.2%), vascularized to caudal tip at 57.9%, with dense faviform parenchyma (3 tiers deep) along cranial 11.4% and sparse edicular parenchyma along caudal 26.0%; right bronchus long (17.3%), extending 0.46 of the length of the right lung with type G foramina located between the tips of adjacent rings; heart elongate and large (5.5%, MP = 17.7%); junction of right and left systemic arches craniodorsad of ventricular apex by 4.7%; heart-liver gap long (8.7%); liver moderate (35.4%, MP = 46.9%), asymmetrical only cranially with right liver extension 0.21 of liver length; liver-gall bladder interval moderate (36.2%); posterior tips of liver overlap gall bladder (liver gall bladder gap –0.4%); gall bladder (MP = 64.8%) adjacent to and between cranial spleen and caudal pancreas; right kidney (3.5%, MP = 78.9%) shorter than left (3.9%, MP = 82.3%); both kidney-vent interval (22.8%) and kidney-vent gap (15.7%) long; enormous rectal caecum twice the diameter of adjacent small intestine and twice the length of that of any other known snake (9.8%).

Mean statistics (plus range parenthetically) for the three known specimens of *L. brasiliensis* are 257.7 mm total length (248–272 mm), 209.3 total middorsals (207–211), 15.3 subcaudals (15–16), length/width ratio 45.0 (38.2–50.6), and relative tail length 6.6% (6.3–6.9%). As the two Barreiras specimens possess three supralabials in contrast to two in the type specimen, it is possible that the type is aberrant for that character and that the diagnosis of *L. brasiliensis* should include "three (rarely two) supralabials." The holotype of *L. brasiliensis* (IRSNB 2049) originated from an unknown locality in Brazil. Since the two specimens with specific locality data (collected 45 years apart) are both from Barreiras, I restrict the type locality of *Leptotyphlops brasiliensis* to Barreiras, western Bahia, eastern Brazil, ca. 12°S, 45°W.

Acknowledgments.—I thank J. B. Rasmussen for the loan of the *Ramphotyphlops albiceps* that settles the question of proper generic assignment of the species *albiceps*, and Arnold G. Kluge (UMMZ) for hospitality offered in 1988 during my visit to the museum and for permission to dissect the *Leptotyphlops* reported on here.

Cnemidophorus univalens Kraemer, 1989: An Erroneous Subsequent Spelling without Nomenclatural Status

JAMES M. WALKER
Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA

HOBART M. SMITH
Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA

and

JAMES E. CORDES
Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA

Within the published symposium, *Is the Organism Necessary?*, presented at the 1987 meeting of the American Society of Zoologists, is an interesting and amusing reference to several real and imagined parthenogenetic species of *Cnemidophorus* by Kraemer (1989), not a herpetologist. To find several paragraphs on *Cnemidophorus* in this symposium by this author was unanticipated to say the least. Kraemer and Walker were colleagues in the same department at the University of Arkansas for nearly 30 years and she was one to whom either the highs and lows of working on lizards in the genus *Cnemidophorus* were mentioned many times. Evidently this individual was particularly intrigued by discussions of the controversial subject of pseudocopulation between individuals of the parthenogenetic *C. uniparens* (e.g., Crews and Fitzgerald 1980), for she ventured to publish on this subject (Kraemer 1989) without our knowledge at the time. In fact, the paper only became known to us when a graduate student asked JMW, "Who described *Cnemidophorus univalens*?" Indeed!

Under the sectional heading "*The "case" of* Cnemidophorus uniparens *(Reptilia: Lacertilia)*," Kraemer (1989:1142) announced an intent to discuss neurendocrine system-reproductive system interrelationships and pseudocopulation in *C. uniparens* and *C. laredoensis*. In the second paragraph of this section there appeared the name *C. univalens*, an apparent lapsus for *C. uniparens*. In the third paragraph the name *C. uniparens* reappeared and with it an unflawed discourse to its end. In the fourth paragraph, however, the gremlins wreaked havoc! Kraemer (1989) noted (with literature citations within the quoted material omitted), "Some scientists working on *Cnemidophorus univalens* are concerned that no one has seen male-like or female-like pseudosexual behavior in nature, even though the behavior has been seen by a number of workers, occurring in caged animals.... Others... have noted that many of the captive behaviors seen in the parthenogenetic species (diploid *C. uniparens* and triploid *C. univalens*) have also been seen in gonochoristic species, between females. It can be argued that the very fact that pseudosexual behavior *occurs*, however, may constitute reason for the controversy, and justifies questioning the present status of the neurendocrine basis of such sexual behavior in *C. univalens*."

To set the record straight for herpetologists who should happen upon Kraemer (1989), there is no parthenogenetic species of whiptail lizard named *C. univalens*. It constitutes an "erroneous subsequent spelling" (in the terminology of the International Code of Zoological Nomenclature) of *C. uniparens*, and as such has no nomenclatural status, and is not even a nomen nudum. Moreover, *C. laredoensis* remains diploid and *C. uniparens* triploid, as before.

TECHNIQUES

Use of Pineal Spot ("Pink Spot") Photographs to Identify Leatherback Turtles

DONNA MCDONALD
Department of Planning and Natural Resources, Division of Fish and Wildlife Lagoon Street Complex, Frederiksted, St. Croix, USVI 00841, USA

PETER DUTTON

Identification of individual sea turtles is crucial to developing biological profiles on these endangered species. Flipper-tagging with metal tags is the method most widely used by sea turtle biologists; tag loss on many nesting beaches is high, however. In St. Croix, U.S. Virgin Islands, the majority of flipper tags on leatherback turtles (*Dermochelys coriacea*) persists for only three to four years (McDonald and Dutton 1994), and only 50–60% are retained through the first remigration (i.e., the first nesting season following tagging) (McDonald and Dutton, *in press*).

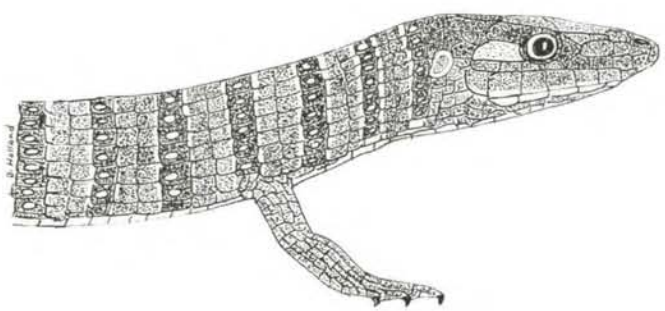
One external characteristic unique to each adult leatherback turtle is a pink spot on the top of the head. Its appearance, including size, shape, color, and pattern appears to be unique to each individual. In 1986, as part of the Leatherback Turtle Research and Conservation Project, researchers began photographing the pink spot of leatherbacks nesting at the Sandy Point National Wildlife Refuge in St. Croix. Photographs were intended to serve as a backup method of identification in case flipper tags were lost. Our study verifies that the appearance of the pink spot is recognizable at the individual level over several years.

Most leatherbacks nesting at Sandy Point were photographed each season from 1987–1994. Because females return to nest every two to five years (Dutton et al. 1994), some individuals have been photographed several times. Six observers examined two sets of photographs: one set of "original," taken in 1987 or 1988, and one set of "subsequent year," taken several years later, for ten individual leatherbacks positively identified by flipper tags. Two of the observers were experienced in studying pink spot photographs ("experienced"); three had worked with leatherback turtles but had never examined pink spot photographs ("semi-experienced"), and one had never worked with leatherbacks ("novice"). Photos were taken seven years apart for one turtle, six years apart for seven turtles, and five years apart for the remaining two. All identification numbers were concealed. Observers were asked to match each photograph in the "original" set with the same turtle

in the "subsequent year" set. Two photographs that had no matches were included in the "subsequent year" set. Observers who were not 100% correct in the first trial were asked to repeat the experiment once (errors in identification were not pointed out to them). Three observers, including the two "experienced" and the one "novice," correctly identified all pairs in the first trial, and the other three were 80–100% correct by the second trial.

These results verify that the size and shape of most pink spots persist for at least five to seven years, and most individual pink spots are recognizable, even by inexperienced observers. Since the remigration interval for leatherbacks on Sandy Point is 2–5 years, this technique may be used to identify remigrants that have lost all flipper tags.

Pink spots can change in appearance, however. All six observers had difficulty matching one of the pink spots due to subtle changes in outline and internal mottling. Camera angle and distance, sand on the turtle's head, glare from the camera flash, and new scars can also affect the appearance of the pink spot. When a turtle is photographed, its head should be free of sand, and the camera angle and distance should be standardized. This method will be most useful for populations in which most (ideally all) individual turtles can be photographed at least once during each nesting season over three to four seasons. Because photo identification is not 100% reliable, and some turtles do not always return to the same beach to nest, this technique should serve as a supplement, not a replacement, for the use of flipper tags.



Acknowledgments.—The Leatherback Turtle Research and Conservation Project, Virgin Islands Department of Planning and Natural Resources, Division of Fish and Wildlife, is funded by the United States Fish and Wildlife Service, and by Earthwatch and its Research Corps. We thank Mike Evans, Zandy Hillis, Amy Mackay, and James Rabholz for participating in the study.

A Capture Technique for Small, Smooth-scaled Lizards

RICHARD D. DURTSCHE
Department of Zoology, University of Oklahoma
Norman, Oklahoma 73019, USA
e-mail: rdurtsche@aardvark.ucs.uoknor.edu

A variety of methods exist for sampling lizards, including pitfall traps, rubber bands, and noosing (Campbell and Christman 1982; Karns 1986; and Simmons 1987); more recently, glue boards (Bauer and Sadlier 1992), refuge tubes, baited lizard sticks (Strong et al. 1993) and extraction hooks (Bedford et al. 1995) have been used. While these techniques are efficient, many are biased toward medium to larger-bodied lizards. Small lizards, including hatchlings and juveniles, and smooth-scaled lizards are often missed or destroyed using these collection methods. Pitfall traps, glue boards, and refuge tubes all rely upon lizards (regardless of size) encountering them. Noosing small lizards may be ineffective, and smooth-scaled lizards will often slip through the nooses—even those tightened around their bodies.

Faced with the difficulty of capturing juvenile *Mabuya unimarginata* (Scincidae) in lowland tropical wet forest leaf litter at the edge of the Rio San Juan in Nicaragua, I combined two partially successful methods into a technique effective for capturing small lizards. By tying a small (8 mm x 30 mm) rectangular piece of "Victor Holdfast® Mouse and Insect Glue Board" (Woodstream, Inc., P.O. Box 327, Lititz, Pennsylvania 17543, USA) to the end of a pole (fishing pole, collapsible car antenna) with two pieces of string (Fig. 1), I created a lizard collecting pole. I use a telescoping car antenna with the sticky pad fastened to the end, and, to increase extension capabilities and usefulness, I use duct tape to secure the antenna to the end of a potato rake (Fig. 1). This allows me to move objects such as rocks and logs to uncover lizards which can then be captured with the sticky pad. Simply touching the sticky pad to the back of the lizard allows for easy capture of these small, delicate, reptiles. Corn oil, applied to the skin, frees lizards from the sticky pad (Bauer and Sadlier 1992); specimens can then be marked, measured, and released with no apparent ill effects. The non-stick, peel-away, cover sheet on the glue boards is replaceable, keeping dirt and litter off

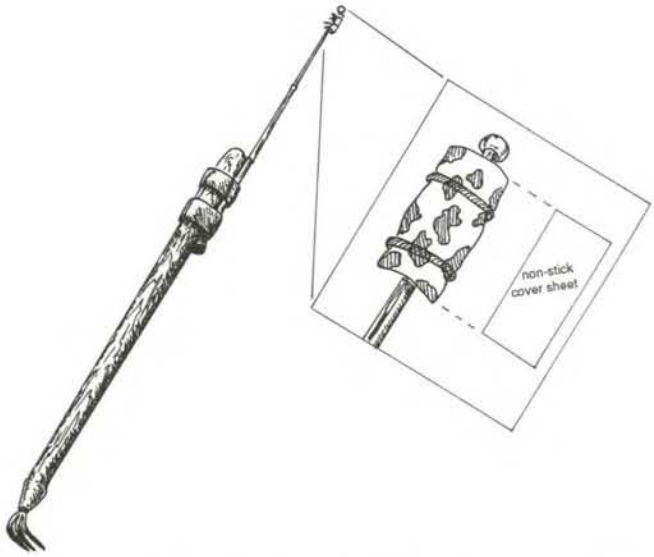

FIG. 1. Lizard pole and sticky pad with disruptive pattern. The non-stick cover sheet is kept on the glue surface when the pad is not in use.

the sticky pads when not in use. I typically cut several rectangular strips from a glue board and carry them with me in a plastic vial, along with extra string, as replacements.

Because lizards respond to the white background of the sticky pad, I create a disruptive pattern on the sticky pad with black, brown, or green Sharpie® marking pens (Fig. 1). From my experience, this does not affect the holding power of the glue. Lizards occasionally respond to these pads, white or with disruptive coloration, as though they represent a prey item; when contacting the pad, they were stuck, and the more active they became, the more they adhered to the glue strip. I have had several *Norops oxylophus* (Polychridae) try to bite the sticky strip.

While intended for use on small, smooth-scaled lizards,this technique is quite effective for extracting a wide range of small to medium-sized lizards from a variety of different microhabitats. Some species I have collected with this technique include: the polychrids *Norops capito*, *N. carpenteri*, *N. humilis*, *N. limifrons*, *N. oxylophus*, and *N. sericeus*, the scincids *Mabuya unimarginata* and *Scincella lateralis*, the crotaphytid *Crotaphytus collaris*, the phrynosomatids *Sceloporus undulatus*, *S. spinosus*, *Cophosaurus texanus*, and *Urosaurus ornatus*, the iguanid *Ctenosaura pectinata*, and the teiids *Cnemidophorus sexlineatus*, *C. sacki*, and *C. costatus*. Using this method, only lizards with a body mass ≤ 10 g (e.g., *Norops capito*) could be captured; larger lizards are not held by the glue.

This non-destructive technique should enable researchers to successfully obtain live specimens of small species and hatchlings and juveniles of lizards that are otherwise difficult to sample.

Acknowledgments.—I thank Jan Caldwell, Randy Nydam, and Laurie Vitt for fruitful discussions about this technique, and for comments on the manuscript.

Tracking Techniques Useful for Field Studies of Anuran Orientation and Movement

BRYAN WINDMILLER
Department of Biology, Tufts University
Medford, Massachusetts 02155, USA

A variety of methodologies is available to field researchers studying the orientation and movement patterns of amphibians. Recapture of marked individuals (Clarke 1974; Oldham 1967; Twitty et al. 1964) and the use of radiotelemetry (Richards et al. 1994; Sinsch 1989; Van Gelder et al. 1986), radioactive tags (Ashton 1994; Kleeberger and Werner 1982; Madison and Shoop 1970; Semlitsch 1981; Williams 1973), and thread bobbins (Dole 1965; Heyer 1994) have been described. The two tracking techniques I describe here, using fluorescent yarn tags and luminescent capsules, offer the advantages of simplicity and low cost, and can be used with anurans too small to track with radio transmitters or thread bobbins. Furthermore, both techniques allow for fine resolution of path orientation, thus permitting the use of circular statistics on ungrouped data (Batschelet 1981).

Fluorescent Yarn Tags.—Fluorescent pigment applied directly to the integument has been used to study the movement of small mammals (Lemen and Freeman 1985), lizards (Fellers and Drost 1989) and turtles (Blankenship et al. 1990; Butler and Graham 1993; Keller 1993). Pigment trails are revealed through the nighttime use of ultraviolet light. Direct application of fluorescent pigment to amphibian skin is problematic, however, as pigment particles adhere strongly to moist amphibian skin and might interfere with trans-cutaneous gas exchange. To circumvent this problem, I applied the pigment to lengths of acrylic yarn and then affixed the yarn to the dorsal skin of juvenile *Rana clamitans* and *R. catesbeiana* as follows: (1) between two and four 100–140 mm lengths of acrylic yarn were cut and arranged in parallel, (2) two 15 mm squares were cut from a roll of self-adhering veterinary bandage material (e.g., Co-Flex™ [available from: Vet Care, Astoria, New York, USA: tel. (800) 767-0508]), (3) one end of each strand of yarn was glued to one of the bandage squares using a few drops of heat-melted glue, (4) the second bandage square was glued onto the first, thus enclosing the yarn ends, (5) the mid-dorsum of the frog was patted dry, and a drop of cyanoacrylate glue was placed on one side of the bandage material which was then pressed onto the frog's skin for one minute, (6) holding the frog securely, the free ends of the yarn were dangled into a plastic bag filled with fluorescent pigment (Radiant Color, Richmond, California, USA: tel. [800] 777-2968) and the pigment was pressed into the yarn. The completed yarn tag weighs between 0.5 and 1 g, depending on amount of yarn, and may be used successfully on juvenile *Rana* as small as 3 g wet weight.

Yarn-tagged frogs were released at predetermined locations, and the release points were marked with fluorescent stake flags inscribed with date, time, toe-clip number of the frog, and color of the fluorescent pigment used. The night following release, fluorescent pigment granules along the frogs' paths were visualized with a long-wave (366 nm) ultra-violet lamp (Blak-Ray™ model ML-49, UVP, Inc., San Gabriel, California, USA) and safety/UV-enhancing glasses. Pigment trails were marked with serially-numbered stake flags placed at 5–10 m intervals and at major turning points. Relocated frogs were affixed with a fresh yarn tag; my observations indicate that re-tagged frogs typically resume their previous heading within 10 m of the release point. The path of the frog was recorded during daylight hours by mapping the stake flags using a tape measure and surveying compass and plotting

the points using CAD software with coordinate geometry capability.

Fluorescent pigment tracking allows determination of the actual paths taken by juvenile ranids for distances up to 150 m, although many trails will become undetectable in less than 50 m. Pigment trail detectability is influenced by ambient light, substrate texture, amount of pigment applied to the yarn tag, and pigment color (blue pigment generally produces the faintest trails, chartreuse produces the brightest). Yarn tags are easily removed by gentle pressure; approximately 30% of marked frogs shed their yarn tags before the resulting trail became undetectable and all tags fell off in the field within 1–2 days. The skin at the point of tag attachment showed some temporary discoloration after tag removal but no lesions were observed; frogs maintained in captivity following fluorescent pigment-tagging showed no apparent ill effects. No tagging-related mortalities were recorded among the 55 frogs released with pigment-coated yarn tags.

Luminescent Capsules.—The second tracking methodology is visual observation of frogs affixed with luminescent capsules. Clark and Gillingham (1984) glued small tubes filled with Cyalume™ fluid (American Cyanamid Co., Wayne, New Jersey, USA) to the backs of anoles to observe nocturnal behavior. This technique may be adapted for use with frogs by extracting luminescent long-duration Cyalume™ fluid from the manufacturer's tube, half-filling an Eppendorf micro-centrifuge tube with the fluid, and then sealing the package securely with the tube's cap. Luminescent capsules may be individually marked using a laboratory marker, glued onto squares of self-adhesive bandage material, and glued to the frogs' dorsal skin as described above. Depending upon the size of the subject, 0.5 ml or 1.5 ml Eppendorf tubes (with final package weights between 0.8 g and 1.9 g) may be used. Luminescent capsules as small as 0.5 g may be made as follows: (1) cut off and keep the cap from a 0.5 ml Eppendorf tube, (2) cut the tube in half transversely, keeping the half with the pointed tip, (3) partially fill the half-tube with Cyalume™ fluid, (4) dip the cap in melted paraffin to ensure a tight seal, and (5) securely seal the half-tube with the cap. It is critical that researchers using this technique ensure that the Eppendorf tubes are well sealed; skin contact with Cyalume™ fluid is fatal to *Rana catesbeiana*, and possibly to other species. Toxic effects can sometimes be reversed if the affected animals are promptly rinsed with copious amounts of cool water.

Luminescent capsules allow simultaneous release, observation, and recapture of groups of 10–60 frogs at two or more release sites; sub-groups of frogs may be distinguished through use of different colors of Cyalume™ fluid. I released the frogs after nightfall in open areas, observed movements over a 2–4 h period, and then recaptured the frogs, marking the final location of each individual with a fluorescent stake flag and taking bearings from release point to recapture point with a surveying compass. Depending upon vegetation density and ambient light, frogs may be visible at distances up to 80 m. Luminescent capsules may be removed with gentle pressure, and the frogs could then be used as paired controls if released later at a different location. About 10% of the capsules fell off the frogs soon after release. Best results are obtained when the capsules are affixed to the frogs in the laboratory prior to transporting them to the release site. Long-lasting Cyalume™ fluid remains bright for at least 12 h.

By determining the actual path taken by anurans, the fluorescent yarn tag method allows the researcher to visualize and test the relationship between path orientation and the spatial distribution of small-scale environmental variables, such as topography, and substrate type. Single paths recorded in the manner described can be analyzed for linearity and for elementary orientation mechanisms by the analysis of turning angles (Benhamou and Bovet 1992). Tracking with luminescent capsules allows the researcher to simultaneously observe the movement of many anurans from a distance and to record such phenomena as the influence of conspecifics on path choice.

Note.—Researchers should exercise care in applying cyanoacrylate glues to the skin of species other than *Rana catesbeiana* and *R. clamitans*. I have observed that cyanoacrylate glues cause severe, and occasionally fatal, skin lesions when applied to spotted salamanders, *Ambystoma maculatum*.

Acknowledgments.—I thank Alison Robbins, Bill Walton, Jude Grimley, and Nancy Jarman for field and laboratory assistance and Frances Chew and Brian Butler for reviewing this manuscript. This research was partially supported by a grant-in-aid of research from Sigma Xi and a graduate student research grant from the Center for Environmental Management, Tufts University.

HERPETOLOGICAL HUSBANDRY

Incidence of Bites from Venomous Reptiles in North American Zoos

WINSTON CARD
and
DAVID T. ROBERTS
Department of Herpetology, Dallas Zoo
621 East Clarendon Drive, Dallas, Texas 75203, USA

Some effort has been made to develop and encourage improved techniques for handling venomous reptiles in zoos (Boyer and Murphy 1994; Gillingham et al. 1983; Hardy 1992; Minton 1994; Mitchell 1984; Murphy 1971; Quinn and Jones 1974; Radcliffe 1975; Reinert and Bushar 1991; Walczak 1991). However, bites from these animals continue to present a potential hazard in zoological parks that maintain venomous reptile collections.

Dallas Zoo staff members circulated surveys to 54 North American zoos in an attempt to determine the incidence of venomous reptile bites in North American zoos over the previous 25 years. Respondents were asked to provide the age and years of experience of victims, the circumstances under which the bites occurred, the species responsible for bites, and the years in which incidents occurred. We did not attempt to quantify any medical aspects of the reported bites, as this report deals primarily with why the bites occurred.

Forty-seven institutions responded, of which 30 had venomous reptile collections in the past 25 years. Of those 30 institutions, 21 reported staff members bitten by venomous reptiles between 1970 and 1995, with several institutions reporting multiple bites within that time period for a total of 31 incidents. Twelve of the 32 victims were between the ages of 20 and 25 years. This represents the largest number of bites for any age group. All twelve of these victims were reported to have had less than five years of professional experience working with venomous reptiles.

Fifteen incidents occurred during routine handling procedures. A significant number of these bites (12) were the result of individuals opening cage doors with their hands or using hooks of an inappropriate length. In one case, the victim was using a 24-inch (61 cm) hook to manipulate a 37-inch (94 cm) snake!

Six bites occurred during feeding episodes. In the most common scenario, a keeper was bitten while tossing a food item into an enclosure without the aid of a tool. Several individuals were also bitten when food items were offered with tools that were of an improper length.

Of the 14 remaining bites, five occurred during handling procedures that involved direct physical restraint without the use of any acceptable restraint devices. Two occurred while animals were being photographed, one during a veterinary procedure, and the remaining six were not described.

Twenty-two bites were inflicted by crotalids and four by elapids. Surprisingly, four bites were inflicted by helodermatids (Table 1). Although this represents a small number of the total, these species are considered relatively benign captives. This assumption probably misleads individuals to handle these lizards carelessly.

TABLE 1. Chronological distribution of venomous reptile bites in North American zoos from 1970–1995.

Year of bite	Species
1970	*Bitis caudalis*
1971	*Sisturus miliarius barbouri*
1972	*Crotalus atrox*
1977	*Naja haje*
1978	elapid (did not specifiy species)
1979	*Agkistrodon piscivorus leucostoma*
1979	*Trimeresurus purpuromaculatus*
1980	*Sistrurus catenatus catenatus*
1980	*Crotalus durissus*
1981	*Agkistrodon bilineatus taylori*
1981	*Crotalus durissus unicolor*
1982	*Agkistrodon contortrix contortrix*
1982	*Crotalus atrox*
1982	*Agkistrodon contortrix*
1983	*Bothrops atrox*
1983	*Agkistrodon bilineatus bilineatus*
1984	*Deinagkistrodon acutus*
1984	*Crotalus horridus*
1985	*Bothrops alternatus*
1986	*Heloderma horridum horridum*
1986	*Agkistrodon bilineatus*
1986	*Crotalus atrox*
1987	*Crotalus cerastes*
1988	*Dendroaspis angusticeps*
1988	*Heloderma suspectum*
1989	*Crotalus lepidus klauberi*
1991	*Heloderma suspectum*
1992	*Crotalus adamanteus*
1992	*Dendroaspis polylepis*
1994	*Crotalus viridis*
1995	*Heloderma horridum horridum*

Although there were no fatalities in this series, all of the reported bites were of a serious nature, with 26 victims requiring extensive medical attention. While safe handling protocols for venomous reptiles are generally a part of standard procedures for most zoos, accidents still occur regularly (about once per year). The majority of bites reported might have been avoided if appropriate protocols were employed. Some of these include using transparent acrylic tubes for physical restraint, using feeding forceps and hooks of appropriate lengths, and never exposing hands or limbs as a potential target. Although these protocols seem to be a matter of common sense, the responses to our survey suggest that they are often overlooked, resulting in most of the bites reported. Perhaps staff members responsible for training new keepers might do more to teach the importance of following protocol at all times.

We hope that by describing the nature and frequency of these incidents, we will stimulate individuals involved in the manipulation of venomous reptiles to be more vigilant.

Acknowledgments.—We thank L. A. Mitchell, A. Walters, M. J. Russell, A. Caldwell, and three anonymous reviewers for their assistance in the preparation of this manuscript. RECENT POPULATION CHANGES

Recent Population Changes provides an outlet for anecdotal or minimally documented information on local extinctions or regional population changes. These reports could be valuable historic indications that might enhance our understanding of very long term (>20 yrs) population trends and changes in distribution patterns.

Extirpation of the Parthenogenetic Lizard *Cnemidophorus tesselatus* from Historically Significant Sites in Pueblo County, Colorado

JAMES M. WALKER

and

HARRY L. TAYLOR
Department of Biology, Regis University
Denver, Colorado 80221, USA
e-mail: hltaylor@regis.edu

Several important studies of the *Cnemidophorus tesselatus* complex of parthenogenetic whiptail lizards have been based in part on specimens obtained from a site east of Interstate Highway 25 (I-25) at 0.8 to 3.2 km north of Colorado State Highway 47, between Jerry Murphy-Overton Road and Fountain Creek (i.e., Overton Road site), in Pueblo, Pueblo Co., Colorado, USA. This site is near, if not the same as, the type locality restrictions for the species by Milstead (1953) and Maslin (1959). Zweifel (1965) based his informal description of *C. tesselatus* Pattern Class A [which Wright and Lowe (1967) and Parker and Selander (1976) later found was triploid], on a study of specimens from the Overton Road site deposited in the University of Colorado Museum (UCM). The Overton Road population was also used by T. P. Maslin and students in the 1960s as the nearest source of *C. tesselatus* for various studies undertaken at the University of Colorado (Pennock 1965; Maslin 1967; Taylor et al. 1967, 1989). Today, the numerous catalogued specimens in the UCM and one in the Carnegie Museum (CM) represent the only vouchers known to us of the past existence of this historically significant and apparently extirpated population of triploid parthenogenetic whiptail lizards.

When JMW and HLT visited the Overton Road site in the 1960s it was possible to find numerous individuals of *C. tesselatus* (e.g., about 10 lizards were collected on 19 May 1963) and *C. sexlineatus* in what was then a City of Pueblo garbage dump. Although there was some mixing of these lizards at that time, the likelihood of finding the desired species could be increased by searching different microhabitats. *C. tesselatus* was most abundant in shrubby growth at the dump site; *C. sexlineatus* was most abundant in grass-weed associations at the dump site.

We now believe that *C. tesselatus* has been extirpated from the Overton Road site since 1973. To our knowledge, the last collec-

tion of *C. tesselatus* made at the site was by E. D. Parker, Jr. in 1971 or 1972 (see Parker and Selander 1976) east of Overton Road, where he found no lizards the next year owing to development of a subdivision (Parker, per. comm.). On 11 July and 10 August 1988 and 4 July 1993, we searched the 2.4 x 0.5 km area west of Overton Road (where Maslin and students collected *C. tesselatus* in the 1960s). We found no individuals of *C. tesselatus* on these occasions, although *C. sexlineatus* was observed and/or collected in all parts of the site and in habitat adjacent to a residential subdivision (which destroyed the habitat where Parker had collected) east of Jerry Murphy-Overton Road. Most of the surface debris in the abandoned dump west of the road had been buried years ago by reclamation work. Today, the Overton Road site is thickly covered with shrubby vegetation, grasses, and weeds (with small openings, roads, and trails) except in an area about 2.8 to 3.2 km north of Colorado Highway 47 where the habitat is more open-structured. We were unable to find *C. tesselatus* in patches of habitat between Jerry Murphy-Overton Road and Fountain Creek south of Colorado 47 (toward the mouth of the creek) and near the confluence of the Arkansas River and Salt Creek where UCM specimens were collected 21 June 1963 by R. L. and J. Holland.

In summary, we have have found no individuals of *C. tesselatus* at any site in Pueblo east of I-25 since we initiated our recent field work in Colorado in 1988. The apparent extirpation of the species from this part of the city most likely resulted from habitat destruction and/or alteration brought on by urban development, changes that have not caused extirpation of *C. sexlineatus* from the area. We have observed individuals of *C. tesselatus* Pattern Class A west of I-25 in Pueblo on the north side of the Arkansas River and on both sides of Pueblo Lake between 1988 and 1995. At some of these sites (e.g., Pueblo Nature Center), *C. tesselatus* was present in large numbers. We hope that any newly obtained records of *C. tesselatus* in Pueblo east of I-25 either be published or made known to us directly.

Acknowledgments.—Hobart M. Smith made several helpful comments on the manuscript. Karen Taylor and James M. Walker, Jr. provided valuable field assistance. R. L. Holland provided information on individuals of *Cnemidophorus* collected by him in 1963. Field work in Colorado was carried out under annual renewals of permits issued by the Colorado Division of Wildlife to the authors through their respective institutions.

NATURAL HISTORY NOTES

The Natural History Notes section (formerly Life History Notes) is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send two copies of manuscripts, double-spaced, directly to the appropriate section co-editor (addresses on inside front cover). Manuscripts concerning reptiles should be sent to Lee A. Fitzgerald; those concerning amphibians should be sent to Charles W. Painter.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins (1990. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 3rd ed., Herp. Circ. 19:1–41; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

ANURA

ELEUTHERODACTYLUS COOKI ("Guajon" or "Demonio de Puerto Rico"). **ECTOPARASITES.** Maldonado Capriles and Medina Gaud (1977. J. Agr. Univ. P. R. 61:402–404) reported larval ticks belonging to the *Ornithodoros talaje* group parasitizing *E. cooki* near Yabucoa, Puerto Rico. We examined 17 *E. cooki* collected 3 km SW of Yabucoa, Puerto Rico, from the herpetology collection of the Natural History Museum, University of Kansas, Lawrence (KU 206049–206050; 276648–276662). Ours is the first report of prevalence, mean intensity of infestation and histopathology for a tick infestation in an eleutherodactyline frog. Infested skin was embedded in paraffin, sectioned at 5 µm and stained with hematoxylin and eosin. Voucher tick specimens were deposited in the U.S. National Tick Collection, Institute of Arthropodology and Parasitology, Georgia Southern University, as RML 121615. Ticks were tentatively identified as *Ornithodoros talaje*. As the hypostome was missing, there is a possibility they might be *Ornithodoros puertoricensis*. However, other morphological characters like length of the palps and configuration of the basis capituli suggest they are *O. talaje* (J. E. Keirans, pers. comm.). The ticks appeared to be randomly distributed over the dorsal body surfaces of all infested frogs. Prevalence (number of infected individuals/number of individuals examined) was 35% (6/17). Mean intensity (mean number of ticks per infected host was 1.5 + 0.5 SD while the range (difference between lowest and highest number of ticks) was 1–2.

The ticks produced a diffuse inflammatory reaction consisting of degranulated heterophils, some lymphoid cells, plasma cells, and occasional histiocytes. There was focal ulceration at the point where the tick hypostome penetrated the integument. We also noted mild epithelial hyperplasia with leucocytic exocytosis. Dermal collagen was infiltrated by inflammatory cells and a thick layer of these mixed leucocytes including many degranulated heterophils was present along the deep dermis.

The only other West Indian *Eleutherodactylus* to be infested with ticks is *E. zeus*, from Cuba (R. L. Joglar, pers. obs.). *Eleutherodactylus zeus*, like *E. cooki*, may be primarily a cave-dweller (R. L. Joglar, pers. obs.).

We thank William E. Duellman for allowing us to examine *Eleutherodactylus cooki* from KU collection, and James E. Keirans, Institute of Arthropodology and Parasitology, Georgia Southern University for identification of ticks.

HOLSHUH**, Comparative Medical and Veterinary Services, County of Los Angeles, Downey, California 90402, USA, and **RAFAEL L. JOGLAR**, Departamento de Biologia, Universidad de Puerto Rico, Rio Piedras, Puerto Rico 00931, USA.

HYLA GRATIOSA (Barking Treefrog). **REPRODUCTION.** On 19 August 1992, we collected two pairs of amplexing *Hyla gratiosa* from open water of a temporary pond northeast of the University of South Florida campus (28°06' N lat., 82°23' W long., Hillsborough County, Florida, USA). Two other pairs were collected in open water on 6 July 1994. In each case, amplexed pairs were transported to the laboratory in separate containers with pond water. Once in the laboratory, pairs were housed overnight in individual aquaria, with fresh tap water. The following morning, within 9 h of capture, eggs had been laid. Eggs were counted and a subsample was measured for ovum diameter and egg capsule diameter with a Wild dissecting microscope at 40X magnification. Most eggs from all the clutches were fertile.

TABLE 1. Length, weight, and fecundity data for four pairs of *Hyla gratiosa*. Date = date of capture; SVL = snout-vent length; WT = weight after oviposition; Egg Number = estimated clutch size; EC = average diameter of egg capsule ± one standard deviation; Ovum = average diameter of ovum ± one standard deviation; N = number of eggs measured.

	Date	SVL	WT (g)	Egg Number	EC (mm)	Ovum (mm)	N
Male 1	19 Aug 92	45	12.3				
Female 1	19 Aug 92	48	13.5	789	1.74 ± .08	1.32 ± .09	16
Male 2	19 Aug 92	51	16.3				
Female 2	19 Aug 92	51	15.2	931	1.74 ± .09	1.33 ± .06	16
Male 3	6 July 94	55	11.1				
Female 3	6 July 94	55	12.0	1535	1.76 ± .08	1.32 ± .09	20
Male 4	6 July 94	62	17.3				
Female 4	6 July 94	61	16.3	1784	1.83 ± .11	1.28 ± .05	20

Clutch size ranged from 789–1784, ovum diameter from 1.12–1.60 mm and egg capsule diameter from 1.55–2.03 mm. Mean ovum diameter and mean egg capsule diameter were not significantly different among clutches (ANOVA, $p > 0.05$) (Table 1). This is similar to values for ovum and capsule diameter found by Wright and Wright (1949. Handbook of Frogs and Toads of the United States, Comstock Publ. Assoc., Ithaca, New York. 640 pp.). This pond has been under observation for five years. At this location, *H. gratiosa* begin chorusing in late February and are rarely heard by late September. Amplexing pairs have been observed

from late May until mid-September. Although *H. gratiosa* ovum and egg capsule diameter were reported by Wright and Wright (1949) we are not aware of any reports of *H. gratiosa* clutch size.

Submitted by **PABLO R. DELIS**, Department of Biology, University of South Florida, Tampa, Florida, 33620, USA, and **ADAM P. SUMMERS**, Organismic and Evolutionary Biology, University of Massachusetts at Amherst, Amherst, Massachusetts, 01003-5810, USA.

RANA CATESBEIANA (Bullfrog). **PREDATION.** The diet of *Dolomedes triton*, the six-spotted fishing spider, includes many insects and small fish (Carico 1973. Bull. Comp. Zool. 144(7):435–488), but predation of *Rana* tadpoles has not been widely documented. Of 625 prey items identified by Zimmermann and Spence (1989. Oecologia 80:187–194) only one of these was an amphibian (female spider, *Rana sylvatica* tadpole). In lab studies (Blechnann and Lotz 1987. Anim. Behav. 35:641–651), *D. triton* was observed capturing *Bufo bufo* tadpoles and juvenile *Xenopus laevis* (2–3 cm).

On 24 March 1994, between 2100 and 2230 h, a gravid female *Dolomedes triton* (identified by James Canco) was captured in the process of feeding on a *Rana catesbeiana* tadpole (verified by George Cline) at a small farm pond 3 miles south of Jacksonville, and 1 mile east of AL Hwy 21 on Longshore Drive, Calhoun Co., Alabama, USA. The spider was hanging from a partially submerged metal structure by the hindmost pair of legs, while grasping the tadpole at the water's surface with the two anterior pairs of legs. The tadpole was ca. 60 mm TL. The tadpole had well-developed hind legs but no visible forelimbs. The cephalic region of the tadpole was necrotic, presumably indicating the point of attack.

Because *Dolomedes triton* feeds on small fish and insects it seems logical that it would also include tadpoles as part of its diet.

LACERTILIA

ANOLIS CAROLINENSIS (Green Anole). **DIET.** *Anolis carolinensis* is known to prey on a variety of insects and other arthropods (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co. Boston, Massachusetts. 450 pp.). Herein, we report predation upon a scorpion by *A. carolinensis*. To our knowledge, this is the first report of predation on scorpions by *A. carolinensis*.

On 18 November 1994 (ca. 1430 h) we observed a male *A. carolinensis* (50.4 mm SVL, 3.4 g) on the side of an abandoned building in eastern Lee County, Alabama, USA. The lizard was gaping and failed to exhibit any escape behavior when approached. It continued to gape after capture and, upon examination, the sting of a scorpion was noticed in its throat. The anole apparently was having difficulty ingesting the scorpion, and 10 min. passed before the scorpion was completely ingested. The following day the lizard was killed and preserved. The scorpion (33 mm TL) was removed from the digestive tract of the anole and determined to be *Vaejovis carolinianus* a small species common in east central Alabama. The anole was deposited in the Auburn University Museum (AUM #33730)

Scorpions are significant components in the diets of several desert lizard species (Pianka 1986. Ecology and Natural History of Desert Lizards. Princeton University Press, New Jersey). These desert lizards either consume scorpions at night, when the arthropods are most active, or encounter them during diurnal foraging when the scorpions are sedentary. Nothing is known, however, concerning the importance of scorpions in the diet of *A. carolinensis*.

We thank Robert Mount for allowing us access to his property and George Folkerts for identifying the scorpion. Brian Butterfield, Craig Guyer, and Karen Schnuelle provided insightful comments.

ANOLIS MAYNARDI (NCN). **ENDOPARASITES.** *Anolis maynardi* is known only from the Cayman Islands where it is restricted to Little Cayman Island and Cayman Brac (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies. Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville, 720 pp.). The purpose of this note is to report on an examination of gastrointestinal tracts from 12 *A. maynardi*. We know of no published reports on the endoparasites of *A. maynardi*. Specimens were borrowed from the Florida Museum of Natural History, University of Florida, Gainesville (UF) or the Division of Amphibians and Reptiles, National Museum of Natural History, Smithsonian Institution (USNM): N = 12, mean snout-vent length, SVL = 61 + 9 SD, range = 49–67 mm, Little Cayman Island, 1965 (UF 21719, 21752-53, 21785–87),1982 (USNM 236622),1986 (UF 63458-61); Cayman Brac, 1986 (UF 63457).

The body cavity was opened by a longitudinal incision from throat to vent. The esophagus, stomach, small intestine and large intestine were examined separately, in situ, using a dissecting microscope. Each parasite was removed and identified using a glycerol wet mount.

The endoparasite fauna of *A. maynardi* consisted of nematodes: *Physocephalus* sp. (prevalence: number infected individuals/number individuals examined = 8%, mean intensity: mean number helminths per infected host = 1); *Gongylonema* sp. (prevalence = 8%, mean intensity = 1); *Parapharyngodon cubensis* (prevalence = 17%, mean intensity = 2); larval spirurid (prevalence = 8%, mean intensity = 1); *Atractis scelopori* (prevalence = 17%, mean intensity = 44). All of our findings represent new host records. Nematodes were deposited in the U.S. National Parasite Collection, (USNPC), Beltsville, Maryland 20705: *Physoceehalus* sp. 84785; *Gongylonema* sp. 84786; *Parapharyngodon cubensis* 84889, 84890; larval spirurid 84891; *Atractis scelopori* 84892, 84893.

We thank Kevin De Queiroz (USNM) and David L. Auth (UF) for permission to examine *A. maynardi*.

Submitted by **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA, and **CHARLES R. BURSEY**, Department of Biology, Pennsylvania State University, Shenango Valley Campus, 147 Shenango Avenue, Sharon, Pennsylvania 16146, USA.

CNEMIDOPHORUS SACKII GIGAS (Giant Spotted Whiptail). **DIET**. Four specimens of *Cnemidophorus sackii gigas* were collected by T. P. Maslin and party on 14-15 June 1972 from a site 8 km N Iguala, Guerrero, México (elevation 870 m). These specimens were deposited in the University of Colorado Museum (UCM 48822, male, SVL = 134 mm; UCM 49830, female, SVL = 132 mm; UCM 49831, female, SVL = 94 mm; UCM 49832, male, SVL = 127 mm). The stomach contents of these specimens were removed and identified. Half of the 64 prey items identified were ants (Hymenoptera, Table 1). However, one lizard (UCM 49830) consumed 23 ants whereas the other lizards consumed less than six ants each; so ants were probably not the most important constituent of these lizards' diets. Beetles and beetle larvae (Coleoptera) were the second most abundant prey type and comprised the majority of the volume of prey consumed and so were more important in the diet of these lizards. All four lizards had many sand grains in their stomachs and three of the four contained nematodes (presumably parasites). No lizard consumed any plant material. We conclude that *C. sackii gigas*, like most whiptail lizards, is insectivorous.

TABLE 1. Diet of *Cnemidophorus sackii gigas* in Guerrero, México. The first column gives the numerical percentage of each prey taxon in the sample (64 prey items). The second column gives the number of lizards in which each prey taxon was found (N = 4 lizards examined).

	Percentage In Sample	Number of Lizards Consuming

Submitted by **MARK A. PAULISSEN**, Department of Biological and Environmental Sciences, McNeese State University, Lake Charles, Louisiana 70609, USA, and **JAMES M. WALKER**, Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA.

CNEMIDOPHORUS SACKII SACKII (Sack's Spotted Whiptail). **DIET.** In June 1969, T. P. Maslin and party collected a series of *Cnemidophorus sackii sackii* from the remote Tomellin Canyon region in southeastern Puebla, México (Walker 1981. J. Herpetol. 15:321–328); these specimens were deposited in the University of Colorado Museum (UCM). We removed and identified the stomach contents of four of these specimens (UCM 38864, female, SVL = 120 mm, collected 2.0 km NE Chilac, elev. 1280 m; UCM 38898, male, SVL = 127 mm and UCM 38905, male SVL = 132 mm, both collected 0.6 km WNW Calipan, elev. 1067 m; UCM 38857, male SVL = 87 mm, collected 2.0 km SW Chilac, elev. 1219 m); all lizards were collected on 20 June 1969. Over three-fourths of the 216 prey items identified were termites (Isoptera, Table 1); however, this is deceiving since one lizard (UCM 38864) consumed 117 termites. Beetles and beetle larvae (Coleoptera) were the second most abundant prey type in lizard diets and the most important volumetrically since most of the beetles and larvae were 20–30 mm in length. All four lizards had at least a few sand grains in their stomachs and three of the four contained nematodes (presumably parasites). No lizard consumed flying insects, jumping insects, or plant material. Maslin and Walker (1973. Herpetologica 29:128–143) observed a *C. sackii sackii* consume part of a discarded pressed ham and suggested this species consumed carrion when available; we found no evidence of this in our sample.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). **AQUATIC BEHAVIOR.** Unusual escape behaviors, including arboreality (Paulissen and Harvey 1985. Herpetol. Rev. 16:27) and aquatic escape (Dillon and Baldauf 1945. Copeia 1945:174; Stille 1947. Copeia 1947:143), have been documented for *Cnemidophorus sexlineatus*. Herein, we report on a third incident involving escape into an aquatic habitat by this species.

During an investigation of herpetofaunal communities within the North Alum Creek watershed of the Ouachita National Forest (Saline County, Arkansas, USA), we had the opportunity to witness aquatic behavior in the prairie racerunner, *C. s. viridis*. On 18 May 1995 at 1303 h CDST three of us (SET, JDW, and LCH) had just left a pine plantation and were walking along a mostly-grassy, timber road when we observed a juvenile lizard (SVL = 38 mm) leap from within vegetational cover of the central path of the lane and dive into a shallow pool of clear water (created by the filling of tire ruts). The lizard swam directly to the bottom of the pool (ca. 120 mm in depth) and buried the anterior two-thirds of its body within in a cup-shaped, mud depression. We waited for the lizard to emerge from its hiding place; the lizard rose to the surface after 1 min 26 sec had elapsed and swam to the edge

of the puddle. We coaxed it out into the pool again, and it dove for a second time to a point beneath a small submerged tree branch. This time the lizard remained motionless with its entire body shielded by the branch for 1 min 56 sec before resurfacing and swimming to the water's edge. We collected the specimen which was catalogued into the Arkansas State University herpetological collection (ASUMZ 20394).

We thank the Weyerhauser Co. for allowing us to perform survey work on its land. This research was conducted and financed in cooperation with Oklahoma State University through grant monies provided by the U.S. Forest Service, the Weyerhauser Co., and the National Council of the Paper Industry for Air and Stream Improvement, Inc.

NESTICURUS BICARINATUS (NCN). **REPRODUCTION.** Instituto Nacional de Pesquisas da Amazonia, number 766 and Museu Paraense Emflio Goeldi, number 16887. Verified by Tereza Cristina Avila-Pires. I found an adult *N. bicarinatus* beside a nest containing two eggs at 1000 h on 31 May 1994. The nest was on a sand bank in undisturbed rainforest, 124 cm from the bank of a small (width = 4.4 m; maximum depth = 0.7 m) stream (Igarape Acara), in Reserva Florestal Adolfo Ducke (Lat. 03°08'S, Long. 60°04'W). The nest was 92 cm above water level and completely open, presumably because I disturbed the female before she could fill the nest. The adult beside the nest was emaciated and it is unlikely that it was carrying more eggs. When I returned at 1030 h the adult had abandoned the nest and I collected the eggs. However, when I returned two days later the hole had been filled. As there was no rain or flooding during that period I assume that the female had returned to close the nest.

The nest was 5.8 cm long, 2.9 cm wide, and 3.6 cm deep. One wall along the long axis was steep and the floor sloped up to the other edge along the long axis. The walls along the short axes were steep. The length, width, and mass of the eggs were 1.76 cm, 1.00 cm, l.l g, and 1.79 cm, 1.01 cm, and l.l g, respectively. They were incubated in vermiculite at room temperature (ca. 30°C) and they hatched 24 August 1994. The incubation period (86 days) may have been shorter than in the field because ground temperatures in the soil near the stream are generally lower (23–27°C). However, I did not measure temperatures at the nest site. At hatching, the total length, snout-vent length, and mass of the hatchlings were 9.9 cm, 3.6 cm, 1.2l g, and 9.6 cm, 3.5 cm and l.ll g, respectively. As the hatchlings weighed as much as the eggs, water must have been taken up during incubation. One egg and one hatchling were deposited in each museum.

Submitted by **WILLIAM E. MAGNUSSON**, Departamento de Ecologia, Instituto Nacional de Pesquisas da Amazonia, CP 478, 69011-970 Manaus AM, Brazil.

SCELOPORUS OLIVACEUS (Texas Spiny Lizard). **SIZE.** Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern North America, 3rd ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.) gave the maximum size of *Sceloporus olivaceus* as 279 mm TL and 121 mm SVL. On 26 June 1994, an adult female *S. olivaceus* (299 mm TL, 113 mm SVL) was discovered at 0230 h inside a house 3.2 km E Edinburg, Hidalgo Co., Texas, USA. The specimen (Michael J. McCoid Private Collection 3151) was gravid with eight palpable eggs. The specimen has been deposited with the TCWC (verified by R. K. Vaughan).

Despite the TL of the above specimen exceeding that reported by Conant and Collins (*op. cit.*), the SVL was less. Since longer SVL specimens have been recorded and female phrynosomatids (usage fide Conant and Collins, *op. cit.*) generally have shorter tails than males, even larger TL *S. olivaceus* are to be expected. The specimen reported here had a pristine tail, suggesting that the 121 mm SVL specimen listed above had an incomplete tail.

Submitted by **MICHAEL JAMES MCCOID**, Caesar Kleberg Wildlife Research Institute, Texas A&M University, Kingsville, Texas 78363, USA, and **DAVID S. HENSLEY**, Route 1, Box 143, Edinburg, Texas 78539, USA.

TUPINAMBIS TEGUIXIN (Common Tegu). **FORAGING.** Tegu lizards are known to be food habit generalists, including small vertebrates in their diets (Dessem 1985. Copeia 1985:245–247; Gudynas 1982. Bull. Chicago Herp. Soc. 16:29–39). On 13 January 1991, at Ilha do Cardoso State Park (25°03'S, 47°53'W) around noon on a very hot day, we observed an adult male tegu (50 cm SVL) following an ash-throated crake (*Porzana albicolis*) and three small chicks. The birds were walking in short grass along the border of a swamp, and the lizard was following them, walking at a normal pace. After three attempts, the tegu managed to catch one of the birds by lunging at it and biting its back. The lizard crushed the bird with its jaws and swallowed it whole, pressing it against the ground to help position it. Later, on 14 December 1992, also at Ilha do Cardoso, another tegu (40 cm SVL) was observed preying on the two eggs of a collared plover, laid in a nest among dune vegetation immediately above high tide mark on a sandy beach. Tegus have commonly been observed foraging in a deliberate zigzagging way among the debris left at high tide and in the adjacent dune vegetation. It is in this area where the plovers nest.

UROSAURUS ORNATUS (Tree Lizard). **AUTOHEMORRHAGING.** I have observed two small, but adult-sized, (SVL = 45 mm, TL = 70 mm, mass = 3.2 g; SVL = 47 mm, TL = 45, mass = 3.9 g) male tree lizards ooze blood from their eyes in response to handling. Both were captured by noosing at Aquirre Spring Recreation Area located 25 air km east of Las Cruces, Dona Ana County, New Mexico, USA. The first incident occurred on 12 May 1992 and the second on 6 July 1994. Both males only ejected blood from one eye, the blood filling the orbit of the eye and trickling down the face. This "oozing" occurred at the moment of capture, specifically, before I had my hands on the lizards. The lizards seemed to be reacting to the stress of sudden capture involving neck constriction and perhaps swinging through the air as I retrieved the noosed animal. Recaptures by noosing of these two lizards at later dates yielded no blood oozing. Blood squirting from the orbital region has been reviewed for horned lizards, *Phrynosoma* (Middendorf and Sherbrooke 1992. Copeia 1992:519–527). Orbital bleeding (autohemorrhaging) has also been reported in several species of dwarf boas in the genus

Tropidophis (Smith et al. 1993. Herpetol. Rev. 24:130–131). To my knowledge, orbital bleeding has not been reported in *Urosaurus*. Middendorf and Sherbrooke (Sherbrooke 1990. Wilson Bull. 102:171–174; Sherbrooke 1991. Amer. Mid. Nat. 126:187–195) found dogs, but not other natural predators, consistently elicited blood squirting in *Phrynosoma cornutum* and interpreted the response as an antipredator defense mechanism against canids. Smith et al. (1993) also reported some species of snakes will autohemorrhage when captured and handled. In these snakes, the blood simply flowed across the eye, under the ocular, and was not forcefully ejected out the orbit region as in *Phrynosoma*. It seems that tactile cues play a significant role in both blood squirting and autohemorrhaging. Therefore, noosing and swinging through the air probably were the stressful tactile cues that brought forth orbit blood oozing (autohemorrhaging) in the *U. ornatus*.

SERPENTES

AGKISTRODON PISCIVORUS CONANTI (Florida Cottonmouth). **DIET.** On 25 October 1993 at 2045 h, we observed a subadult *Agkistrodon piscivorus conanti* scavenging on the carcass of a wild hog (*Sus scrofa*) that had been butchered and dumped from a bridge crossing Cypress Creek on State Road 71, 15.3 km south of County Road 386, Gulf County, Florida, USA. We observed the snake for 25 min from the bridge (ca. 3.5 m overhead) as it manipulated long strips of fat and with difficulty, eventually swallowed portions.

Agkistrodon piscivorus is an opportunistic feeder and frequently scavenges. Gloyd and Conant (1990. Snakes of the *Agkistrodon* Complex. SSAR, Oxford, Ohio) provide an extensive literature review of the diet. However, we believe this is the first report of a cottonmouth scavenging on the carcass of a wild hog.

We thank Steve DeCresie and Brian Bearwood for accompanying us in the field.

Submitted by **GEORGE HEINRICH**, P.O. Box 61301, St. Petersburg, Florida 33784-1301, USA, and **KARL R. STUDENROTH, JR.**, 4434 Dorothy Dr., Apt. 3, Marianna, Florida 32446, USA.

AGKISTRODON PISCIVORUS PISCIVORUS (Eastern Cottonmouth). **COLORATION.** On 3 August 1994, a 72 cm SVL gravid *Agkistrodon piscivorus piscivorus* was captured in the Savannah River Swamp on the Savannah River Site near Aiken, South Carolina, USA. The normally-pigmented female was returned to the lab and gave birth to five young on 3 September 1994. The litter consisted of two live-born hypomelanistic males, one live-born normal male, and two stillborn normal males. The young of this litter were larger (SVL average = 22.92 cm, SD = 0.59 cm; mass average = 20.32 g, SD = 0.55 g) than those of 10 other litters (mean SVL = 20.05–22.76 cm, mean mass = 12.27–19.83 g) born around the same time from females in the same population. The patterns of the hypomelanistic neonates were normal, having reddish-brown dorsal bands lined with white on a yellowish-tan ground color (Fig. 1). The venters were light tan with reddish-brown blotches. The eyes were the same colors as the dorsal bands and ground colors. One of the hypomelanistic neonates died upon eating a cage mate and is specimen #3483 in the Savannah River Ecology Laboratory natural history collection. The other is being maintained in captivity for educational use through the SREL Outreach Program.

The author thanks R. A. Seigel, M. S. Mius, and J. W. Gibbons for comments on the manuscript. Research related to this observation was supported by Contract DE-AC09765R00-819 between the University of Georgia and the U.S. Department of Energy.

BOIGA IRREGULARIS (Brown Tree Snake). **DIET**. The diet of *Boiga irregularis* is fairly well known in its native range (Shine 1991. Copeia 1991:120–131) and in areas where it has been introduced (Savidge 1988. J. Herpetol. 22:275–282). A major component of the diet is birds (adults, nestlings, and eggs). On 4 October 1994 at approximately 2100 h we found a brown tree snake on the road just south of Paluma township in north Queensland, Australia in the process of consuming a pale-yellow robin (*Tregallasia capito*). On closer examination it became clear that the bird was a road-kill. Records of snakes consuming dead prey (including road-kills) are not uncommon (e.g., Bedford 1991. Herpetofauna 21:35) but to our knowledge this type of behavior has not previously been recorded for *B. irregularis*. As mentioned above, however, they are known to consume stationary prey such as bird eggs. In addition, *B. irregularis* are opportunistic predators (Savidge, *op. cit.*) that use chemical cues for foraging (Chiszar et al. 1988. Amphibia-Reptilia 9:77–88) so this record of a snake eating a dead prey item is not unexpected.

Submitted by **GEORDIE A. TORR** and **STEPHEN J. RICHARDS**, Dept of Zoology, James Cook University, Townsville, 4811, Australia.

BOTHROPS ATROX (Common Lancehead). **FORAGING BEHAVIOR and OPHIOPHAGY.** Recently, Martins and Gordo (1993. Herpetol. Rev. 24:151–152) reported finding colubrid snakes in the stomachs of *B. atrox* collected in disturbed areas in

Pará, eastern Amazonian Brazil. Snakes were found only in juvenile *B. atrox* and comprised 7% of 44 prey items. Observations on snakes feeding under natural conditions are scarce in the literature. Here we describe an observation of a subadult female *B. atrox* eating a colubrid snake in primary forest in Central Amazonia, Brazil.

The observations were made during a radio-tracking study of *B. atrox* begun in December 1993 at Reserva Florestal Adolpho Ducke, a 10,000 ha tract of primary forest under protection situated 26 km north of Manaus, State of Amazonas, Central Amazonia, Brazil. On 2 December 1993, a subadult female (900 mm SVL, 137 mm TL, 230 g) was surgically implanted with a 14 g radio transmitter (SI-2, Holohill Systems Ltd.) and released 21 h following capture. Within several days the snake seemed normal in its behavior and was tracked 2–3 times weekly thereafter. All observations reported here were made at distances of 2–5 m and did not appear to affect behavior even during close approaches by the observer (2 m). Voucher photographs of the predation are in the authors' diapositive files.

On most occasions the tagged snake was found, both during the day and at night, to be tightly coiled on the leaf litter, either exposed or in retreats. However, at 1230 h on 17 April 1994, it was found moving through leaf litter on the forest floor. The snake was not followed at this time, but when relocated 2 h later, it was crawling slowly on the margin of a small stream (ca. 80 cm wide), and stopped upon our approach. One of us (MM) followed it from 1435–1525 h while it moved about 10 m on the stream margin, consistently probing the substrate (fallen leaves, branches, low plants, the bases of tree trunks) with frequent tongue flicks. At 1525 h it began to climb a hill and stopped on a fallen tree trunk (ca. 10 x 60 cm), 1.5 m from the stream. Three minutes later it was observed grasping and pulling an already immobile snake (*Atractus torquatus*, TBL ca. 600 mm) from behind the log (the strike was not witnessed because the snake's head and prey were behind the log). The head and neck of prey were in the ground with three fourths of the body exposed. The *B. atrox* failed to pull the prey from underground and lost its grasp. The prey was grasped again near the cloaca, immediately released, and the pitviper's mouth rubbed on the substrate (an apparent aversion by the predator to cloacal secretions of the prey). The prey was nosed several times in an apparent attempt to locate the head, and at 1535 h the anterior fifth of the body was grasped, pulled from the soil while moving 1.5 m backwards, and released. The body was probed in both directions until the head was seized and swallowing begun at 1539 h. At 1610 h the tip of the prey's tail was hanging from the pitviper's mouth and it had resumed tongue flicking. By 1613 h swallowing was complete and the pitviper remained still for 24 min before moving away.

Based on our records for *A. torquatus*, the prey's mass was 40–60 g and using the initial weight of the *B. atrox*, the prey/predator mass ratio of this event would be 0.17–0.26. The observation described above corroborates our impression (unpubl. data) that although a primarily nocturnal, thermally oriented, sit-and-wait predator, *B. atrox* also forages actively during daytime for ectothermic prey using chemoreception.

The mentors of our study, H. Greene and D. Hardy, Sr., kindly shared their friendship and experience, and provided the equipment. D. Hardy and I. Sazima critically read the manuscript. K. Zamudio assisted with field work. Our work at Reserva Ducke was kindly allowed by the Instituto Nacional de Pesquisas da Amazonia and CNPq provided a grant to MM.

CROTALUS HORRIDUS (Timber Rattlesnake). **MATING.** Male accompaniment of female rattlesnakes, prior to courtship and mating, has been described by Duvall et al. (1992. *In* Biology of the Pitvipers, Selva Press, Tyler, Texas: pp. 321–326) in *Crotalus v. viridis* and by Macartney and Gregory (1988. Copeia 1988:47–57) in *Crotalus v. oreganus*. In both studies, sexual attractiveness and receptivity were correlated with female ecdysis. There are few records of these behaviors in *Crotalus horridus*. In a long-term study in Virginia, Martin (1993. J. Herpetol. 27:133–143) observed mating activity five times from 21 August to 18 September in different years. One of these observations was of a male courting a pre-molt female (W. H. Martin, pers. comm.). Brown (J. Herpetol., *in press*) observed male accompaniment of vitellogenic females from 15 July to 25 September over a 12-yr period in New York, noting that such behavior preceded courtship and mating. He noted a correlation between sexual attractiveness and female skin shedding.

There are no records of free-living *C. horridus* mating in North Carolina (W. M. Palmer, pers. comm.). During the period 12–15 August 1994, using radiotelemetry, I observed a sequence of reproductive behaviors in a pair of *C. horridus* which culminated in copulation. These observations occurred in Hanging Rock State Park, Stokes County, North Carolina, USA and are summarized below.

On 12 August at 1745 h, a pre-molt adult female (90 cm total length; containing a transmitter) was found accompanied by an adult male (100 cm TL). The snakes were coiled loosely together, the male in a superior position. On 14 August at 1245 h, the female and the same male (identified by rattle count and body pattern) were located 4 m from their previous location. They were coiled together with the male in an overlying superior position. Both snakes were partially concealed in low vegetation. The female had not shed.

On 15 August at 1345 h, the pair was found copulating. The snakes were aware of, but did not seem concerned about, a human observer nearby. The female was freshly shed, as indicated by her bright appearance and by the addition of a new rattle segment. The snakes were fully extended and facing in opposite directions while coupled. The female's tail was pointed upward and the region immediately anterior to her cloaca was distended. The male was copulating with his left hemipenis, while the right hemipenis was not visible. The male's tail lay to one side, curved back along his body (Fig. 1).

Twenty minutes after my initial observation, the female began a series of forward movements. In response to these movements, the male began a reverse rectilinear locomotion (backing up) to remain coupled with the female. The male was adept at these reverse movements, negotiating obstacles of vegetation, fallen limbs, and other forest debris. At no time did I observe the male being dragged by the female. Forward movements initiated by the female were made at approximately 10-min intervals and averaged about 0.5 m in distance.

Immediately prior to, and continuing throughout each of these movements, the female exhibited a behavior I describe as slow tail lashing. Her tail was curled sharply, left or right of the mid-dorsal line, until her rattle was pointed down (Fig. 1). Once reaching this position, the tail was slowly uncurled until the tail was

fully extended to a vertical position and then was curled down on the opposite side. These slow tail lashes were repeated during each forward movement. Tail movement ceased when forward motion ceased. After 3 h the snakes had moved a distance of 10 m, and the female entered an area of dense cover and coiled loosely. The pair was still coupled and the male was fully extended. At 1830 h I left the snakes while they were once again extended in opposite directions. The next day (16 Aug), I found the female coiled in dense vegetation 55 m away. The male was not found.

I thank the personnel at Hanging Rock State Park for their steadfast support and contribution to this study. Radiotelemetry of *C. horridus* in Hanging Rock State Park is partially funded by the North Carolina Wildlife Resources Commission Nongame and Endangered Wildlife Small Grants Program. I am grateful to W. S. Brown, W. H. Martin, W. M. Palmer, and A. B. Somers for sharing information and advice, and for reviewing the manuscript.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **BEHAVIOR.** On 18 August 1994 at two locations in Badlands National Park, South Dakota, USA, separate adult prairie rattlesnakes were observed each with a group of young. One snake with young was found in a burrow within a black-tailed prairie dog *(Cynomys ludovicianus)* colony, while the other adult with young was found on the edge of the prairie dog colony nestled within a bed of cactus *(Opuntia* spp.). The adult rattlesnake in the cactus bed was seen with 4–6 young snakes ca. 20 cm in total length. The adult rattlesnake within the prairie dog colony had six young rattlesnakes ca. 20 cm in total length. On 25 August 1994, the young were still present with the adult at the cactus site. The other site was not examined. On 8 September 1994, the cactus site was visited again, and no snakes were seen. Also on this date, recent shed skins of the adult and three of the young were found around the aggregation site. Prior to observing the adult rattlesnake with young at the cactus site, this rattlesnake was observed for approximately one month at this same location. Two weeks before observing this adult with young, no young snakes were present.

The sex of the adult rattlesnakes is unknown, but most likely they were female. Nor do we know the exact date of the birth of the young. However, the young stayed with the adult for at least one week after initial observation, perhaps suggesting parental care and nesting behavior.

We also noted intense rattling by the adult rattlesnake in the cactus bed prior to the presence of young; this animal's rattling was heard well in advance of our arrival. Yet when the snakes were observed on the afternoon of 18 August, the adult rattled only after being disturbed.

HETERODON PLATIRHINOS (Eastern Hognose Snake). **DEFENSIVE BEHAVIOR**. Platt (1969. Univ. Kansas Publ. Mus. Nat. Hist. 18:253–420) described death feigning by hognose snakes as the terminating stage in a sequence of defensive behaviors and usually is displayed only after experiencing extreme levels of provocation from man. At 1800 h on 20 May 1993, I encountered a pair of copulating hognose snakes both of which had been radiotracked for several weeks. The male (47. 5 cm SVL, 111 g) had trailed the female (65.5 cm SVL, 219 g) for three days, traveling at least 600 m. When I physically disturbed the copulating snakes, both immediately turned ventral side up and became limp, feigning death typical of the species. The behavior was not preceeded by either the escape or threatening stages or by the extreme writhing and cloacal discharge often seen in death feigning. The remarkable observation is that the pair remained in copulation while feigning death (Fig. 1). Left undisturbed for about 15 min, the female ceased feigning, began moving, and dragged the still feigning smaller male for about 65 m until they separated.

FIG. 1. *Heterodon platirhinos* feigning death while in copulation. The smaller male is underneath the female.

HETERODON SIMUS (Southern Hognose Snake). **HATCHLING SIZE.** Although clutch sizes have been reported for *Heterodon simus* (Edgren 1955. Herpetologica 11:105–117; Price and Carr 1943. Copeia 1943:93), no information exists on the size of hatchlings.

I collected five freshly road-killed *H. simus* between 26 and 28 October 1994 along a 0.6 km stretch of Range Road 234 on Eglin Air Force Base, Okaloosa County, Florida, USA (T1S, R25W, Sec. 12). The surrounding habitat consists of longleaf pine-turkey oak sandhill invaded by off-site sand pine. All five individuals were closely examined and found to have obvious umbilical scars and empty digestive tracts. These observations led me to conclude that these individuals were recent hatchlings and possibly dispersing siblings of this secretive, semi-fossorial species.

Snout-vent length ranged from 139–147 mm (mean 143.4) and total length ranged from 160–173 mm (mean 166.8). All individuals were deposited in the Auburn University Museum (AUM 33734-38).

I thank Craig Guyer and John Palis for reviewing the manuscript.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

LAMPROPELTIS GETULA SPLENDIDA (Desert Kingsnake). **DIET.** On 15 May 1995 at 2211 h, a yearling female *L. g. splendida* (335 + 50 mm, 22.2 g; TJL 102) was captured crossing TX FM 192 near its jct with TX FM 34 and placed into a snake bag. The following morning a half-digested female *Tantilla* sp. was found at the bottom of the bag (210 [incomplete] + 60 mm, 7.7 g [preserved]; UTEP 16001). The *Tantilla* was missing the anterior third of its body and a partially digested centipede, *Scolependra heros* (85+ mm), was protruding from its body wall. The inference is that soon after the *Tantilla* ingested the centipede, it was in turn eaten by the *Lampropeltis*. Using preserved specimens from the UTEP collection and data from Cole and Hardy (1981. Bull. Amer. Mus. Nat. Hist. Vol. 3: Art. 3:201–284) to estimate a tail length/total length ratio, we hypothesize that the consumed *Tantilla* was a *T. nigriceps* having a total length of 317 mm, which was 82% of the total length of the *Lampropeltis*. Published accounts listing generic ophidian prey of *Lampropeltis getula* include *Carphophis, Heterodon, Elaphe, Hypsiglena, Lampropeltis, Masticophis, Pituophis, Thamnophis, Agkistrodon,* and *Crotalus* (Blanchard 1921. U.S.N.M. Bulletin 114, vi + 260 pp; Wright and Wright 1957. A Handbook of Snakes of the United States and Canada. Cornell Univ. Press, Ithaca, xvi + 1105 pp.; Stark 1985. Herpetol. Rev. 16(3):79, 81.). *Tantilla* is now added to this list.

Thanks to C. S. Lieb, W. P. MacKay, and R. G. Webb for helpful comments and suggestions to the manuscript.

MICRURUS FULVIUS FULVIUS (Eastern Coral Snake). **DIET.** Snakes compose a major part of the diet of *Micrurus fulvius*. Prey lists reported by Jackson and Franz (1981. Herpetologica 37:213–228) and Greene (1984. *In* R. A. Seigel et al. (eds.), Vertebrate Ecology and Systematics. Univ. Kansas Mus. Nat. Hist. Spec. Publ. No. 10, pp. 147–162) include 21 snake genera. This note documents an additional genus.

On 13 January 1993, a large female *M. f. fulvius* (SVL= 89.6 cm, TL= 97.9 cm) was trapped in a double-opening funnel trap used with a drift fence array in scrubby flatwoods (Myers and Ewel 1990. Ecosystems of Florida. Univ. Central Florida Press, Orlando, 765 pp.) at Boyd Hill Nature Park, St. Petersburg, Pinellas County, Florida, USA. After removal from the trap, the *Micrurus* regurgitated a partially digested Florida scarlet snake (*Cemophora coccinea coccinea*). The *Cemophora* was a female with a remaining total length (undigested portion) of 50.5 cm and tail length of 7.9 cm; a total length of 57.2 cm was estimated from a known mean tail length/total length ratio for females (Williams and Wilson 1967. Tulane Stud. Zool. 13:103–124).

I thank Dale R. Jackson for reviewing a draft of this note.

MICRURUS MIPARTITUS (NCN). **POLYMORPHISM.** Different color morphs of Costa Rican *M. mipartitus* have been described (Villa 1972, Brenesia 1:10–13; Savage and Vial 1974, Rev. Biol. Trop. 21(2):295–349). Here we report for the first time the co-occurrence of different phenotypes of this species. In the period of 23 July 1993 to 8 September 1993, four specimens of *M. mipartitus* were collected in Rara Avis, 19 km SE of Estación Biológica La Selva, Heredia Province, Costa Rica.

The four specimens represented three different phenotypes: bicolor black and orange (two specimens: A and C), bicolor black and white (specimen D), and tricolor black, white, and orange (specimen B) (specimens ordered chronologically). Specimen A had a total length of 23 cm and 59 orange body rings; specimen B, 21 cm, 50 white/orange/white body rings; specimen C, 51 cm, 48 orange body rings; specimen D, 44 cm, 55 white body rings.

It is unlikely that the color variation is size-related, since juvenile A and adult C shared the same orange phenotype while individual D, having a white phenotype, was of intermediate size. Individuals C and D, two entirely different color morphs, were caught within the same week at locations less then 100 m apart.

Even our limited data show that this is not a size-related, geographical, or seasonal phenomenon, but a true case of polymorphism. The exact function of polymorphism in *M. mipartitus* is not clear and requires further investigation. The highly venomous coral snakes are often hypothesized to be involved in mimicry systems, serving as models for non- or mildly venomous colubrid mimics. In dynamic Batesian mimicry systems, the survival of the model should decrease as the resemblance of a mimic increases. Hence, Batesian models should be expected to evolve different aposematic color patterns as a coevolutionary response to selection resulting from successful mimics (Huheey 1988, Am. Nat. 131:S22–S41). Therefore, the polymorphism in *M. mipartitus* may represent an evolutionary escape from mimics with color patterns similar to those of one or more forms of *M. mipartitus*. Possible colubrid mimics collected in sympatry in Rara Avis are *Geophis brachycephalus, Liophis epinephalus,* and *Oxyrhopus petola*. Specimens C and D were deposited in the Instituto Clodomiro Picado, Universidad de Costa Rica, Costa Rica.

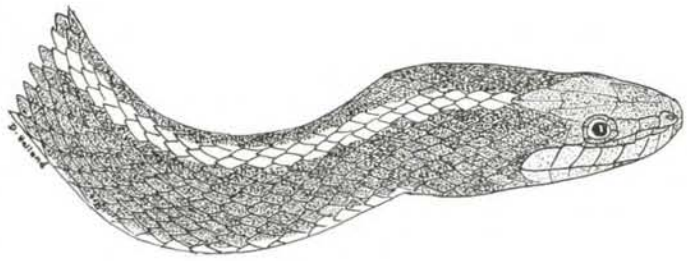
PITUOPHIS MELANOLEUCUS CATENIFER (Pacific Gopher Snake). **PREY.** During a study of habitat use by San Joaquin antelope squirrels *(Ammospermophilus nelsoni)* on the Carrizo Plain Natural Area, near California Valley, San Luis Obispo County, California USA,we captured, PIT-tagged, radio-collared, and released an adult female (155 g) squirrel on 14 July 1994. Over the next week, we radio-located this squirrel at least once a day. On 21 July, we first noticed the squirrel had not moved from a burrow and we speculated that it had been eaten by a snake. The weak radio signal from the transmitter remained in the same position until 27 July when it moved 39.4 m (straight-line distance) to the west. We originally tried to retrieve the transmitter on 22 July, but after excavating a rodent burrow to a depth of 1.4 m below the surface and still not reaching the transmitter, we gave up and reconstructed the site. A second attempt to retrieve the transmitter was made on 4 August when we suspected the transmitter was closer to the surface of the ground based on a stronger radio signal. After digging about 20 cm into a rodent burrow system, we found the transmitter inside an adult (120 cm SVL, 723 g), female, Pacific gopher snake *(Pituophis melanoleucus catenifer).* The captured snake had cloudy eyes and was apparently ready to shed. It was then housed in captivity for 5 days and x-rayed to verify the location of the radio-collar and PIT tag originally placed on, and in, the antelope squirrel. On 9 August, the snake passed the intact collar and functioning transmitter (40 mm diam, 2.6 g mass), as well as the PIT tag, and was released the next day at the site of capture.



Although gopher snakes are known to prey upon a wide variety of rodents (Stebbins 1954. Amphibians and Reptiles of Western North America. McGraw Hill Book Co., New York. 536 pp.), these observations provide the first record of predation on *A. nelsoni* by *P. m. catenifer.* More importantly, these observations suggest that at least some medium-sized snakes (>100 cm SVL) can eat and pass, without ill effect, radio-collars fitted on live rodents.

Our thanks to Kathleen M. Sharum, Margaret B. Harker, and Thomas G. Murphey for assistance in radio tracking and John B. Truax for providing the x-ray of the snake. The Bureau of Land Management and The Nature Conservancy graciously allowed us to pursue our study on properties under their administration. Permits to conduct this research were provided by the California Department of Fish and Game.

Submitted by **MARK R. JENNINGS*, GALEN B. RATHBUN,** and **CATHERINE A. LANGTIMM,** National Biological Survey, California Pacific Science Center, Piedras Blancas Research Station, P.O. Box 70, San Simeon, California 93452-0070, USA. *MRJ: Research Associate, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-9961, USA.

PSEUDECHIS COLLETTI (Collett's Blacksnake). **TWINNING.** Though not terribly uncommon in snakes, twinning has usually been reported for colubrids (Burkett and Huggins 1985. Herptol. Rev. 16:56; Singh 1973. Herpetologica 29:19–20). On 11 August 1994, twin Collett's blacksnakes were hatched at the San Diego Zoo. The clutch of 16 eggs was laid on 10 June 1994 by our long-term captive female. The eggs were incubated at 29.4°C in an airtight, covered Tupperware™ container filled with a 1:1 mixture of vermiculite and water. Average incubation time for this species is around 60 days. At oviposition, the eggs averaged 52 mm x 33 mm and had an average weight of 34.7 g. Six of the eggs went bad within the first month and were opened. Of the six eggs, five were fertile with embryos just starting to develop, the other showed no signs of fertility. On the sixty-first day, four eggs had slit and were removed for hatching. Upon inspection the next morning, five hatchlings were found inside the box. Two of the hatchlings were noticeably smaller and had distinctive kinks at the end of their tails. No other snakes in the clutch had kinked tails. The twins weighed 7 g and measured 24 cm total length (TL) and 10 g and 26 cm TL, respectively. The rest of their clutch mates averaged 17.6 g and 31.2 cm TL. The yolk was not recovered from the egg with the twins so it is not known if they are fraternal or identical twins. Two remaining eggs slit, and were left for hatching. When the snakes had not hatched after three days, they were opened for observation. One egg had a fully formed but dead individual, and the other contained another set of twin snakes. In this instance, two yolk sacks could clearly be seen. Unfortunately, the snakes were not preserved. This represents the first incidence of twinning found for *P. colletti*. The living twins remain in the collection of the San Diego Zoo.

WANTED: HERPETOLOGISTS OR SNAKE KEEPERS. For part-time on-call work to begin in 1996 season in your area. MUST HAVE at least 5–10 years experience working with or extensive knowledge about snakes indigenous to your area, reliable transportation, flexible hours, telephone with answering machine. Applicants must be readily contactable, i.e., have EITHER pagers, mobile or work phones, be at least in mid-twenties and must be willing to sign and comply with terms of a No Compete-Nondisclosure agreement and a waiver of liability. Pay averages $10-15 per hour of work (some mileage will be paid for distances greater than 25 miles). For the location, capture and removal of snakes from the properties of customers as well as educating customers about snakes found in their locality, and the benefits these animals provide. Emphasis is placed on promoting the conservation of the animals by educating our customers. Looking for serious applicants from the following states and areas ONLY: MD, WV, PA, western VA, OH, IA, DE, IN, IL, MO, KY, TN, NC, GA, AL, northwestern FL, MS, AR, TX, OK, KS, NB, CO, NM, AZ, UT, NV, OR, NJ, and NY. For detailed position description and application packet/No Compete agreement, write to: Michael Weeks, 1913 Dannemora Drive, Virginia Beach, VA 23456. Please include your area code/phone number. No inquiries from pet dealers, rattlesnake round-up types, or the idly curious. Please!

Delayed Fertilization in the Monitor Lizard *Varanus gouldii*

Delayed fertilization has been reported in a large number of squamates (Blackwell 1954; Darevsky 1971; Fitch 1970; Greer 1989; Groves 1973; Haines 1940; Joss and Minard 1985; King 1977; Philipp 1979; Wall 1905; Woodward 1933), but there has only been one suspected instance reported in varanids (Auffenburg 1981). This report describes a case of delayed fertilization in *Varanus gouldii* at the Dallas Zoo.

A pair of *V. gouldii* were observed copulating on several occasions between 2 July and 17 September 1994. On the latter date, the male was removed due to a dermal infection. Twenty-one days later, the female deposited a clutch of ten eggs. After a few weeks these eggs began to desiccate and fertility could not be determined. The same female deposited a second clutch of eight eggs 65 days after oviposition of the first clutch. After three months of incubation, a fiberoptic egg candler revealed the presence of embryos and blood vessels, confirming fertility in four of the eggs. The male had not been housed with the female after 17 September 1994. Since gestation is unknown for this species, the exact length of sperm storage cannot be determined.

Acknowledgments.—We thank J. B. Murphy, L. A. Mitchell, C. M. Garrett, D. M. Boyer, D. T. Roberts, K. A. Bradley, and A. C. Walters for helpful advice in the preparation of this manuscript.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in volume 26, number 1.

CAUDATA

AMBYSTOMA TAYLORI (Taylor's Salamander). **RECORD SIZE.** *Ambystoma taylori* is a poorly studied Mexican salamander endemic to Laguna Alchichica, one of several crater lakes (axalapazcos) in the llanos of eastern Puebla, México, located at 2345 m (97°24'00"WL, 19°24'13"NL). The maximum snout-vent length (SVL) reported for *A. taylori* is 113 mm (Brandon et al. 1981. S. California Acad. Sci. 80(3):112–125.). Herein I report a female 126 mm SVL (to the median point of the cloaca), 230 mm TL, and 76.04 g live wet weight collected 27 February 1994 at 2030 h. The specimen was found struggling in a vertical position at the surface of the lake approximately 1 m from the edge. At this point the lake is approximately 1 m in depth. The specimen (ENEPI 6035) is deposited in the herpetological collections at the Universidad Nacional Autonoma de México, Campus Iztacala. I am grateful to Julio Lemos-Espinal who read an initial draft of this note.

Submitted by **MIGUEL ANGEL SANTINELLI-RAMOS,** Fuente de Tauro #15, Lomas de Tecamachalco, Edo. de México 53950, México.

ANEIDES FERREUS (Clouded Salamander). **REPRODUCTION.** Arboreality is common among tropical plethodontid salamanders (Lynch and Wake 1976. Nat. Hist. Mus. Los Angeles Co. Sci. Bull. 25:1–65), and it is probable that many of these species nest in trees (e.g., Good and Wake 1993. Herpetol. Monogr. 6:131–159; McCranie and Wilson 1993. Herpetol. Rev. 23:115–116). However, temperate plethodontids are generally terrestrial or fossorial (but see Jaeger 1978. Copeia 4:686–691; Madigon and Shoop 1970. Science 168:1484–1487), except for some members of the genus *Aneides*. Stebbins (1951. Amphibians of Western North America. Univ. California Press, Berkeley) reported *A. lugubris* in tree cavities as high as 20 m, and also reported nesting sites in hollow trees. Van Denburgh (1916. Proc. California Acad. Sci. 4th ser. 6(7):215–221) reported *A. ferreus* 6.6 m high in a snag, and Leonard et al. (1993. Amphibians of Washington and Oregon, Seattle Audubon Society, Seattle, Washington) reported *A. ferreus* 40 m high in a snag. Dunn (1942. Copeia 1942:52), and Storm (1947. Herpetologica 4:60–62) described nests of *A. ferreus* in decaying logs; however no tree nests have been reported. During August 1988, one of us (RAW) was examining the canopy foliage of recently felled trees from a logging operation in an old-growth stand at the Yurok Experimental Forest in Del Norte Co., California, USA, for evidence of marbled murrelet (*Brachyramphus marmoratus*) nests. The forest was predominately redwood (*Sequoia sempervirens*), with western hemlock (*Tsuga heterophylla*) and Douglas-fir (*Pseudotsuga menziesii*). The trees being harvested were 70–100 m in height, with breast height diameters of 2–3 m and first limbs >20 m above ground. On a large redwood tree RAW discovered a cluster of six salamander eggs. The egg cluster had been dislodged from a fern clump (*Polypodium* spp.) that had broken open from the impact of felling. No adult salamander was observed in attendance when the cluster was discovered. The fern was at the base of a limb

located 30–40 m above ground; tree height was ca. 80 m and diameter ca. 3 m. The egg cluster measured ca. 3 cm diam. The eggs were collected and brought into the lab where three of the six eggs hatched about one week later. The hatchlings were identifed as *A. ferreus* by HHW.

Submitted by **HARTWELL H. WELSH, JR.**, Redwood Sciences Laboratory, 1700 Bayview Dr., Arcata, California 95521, USA, and **RANDOLPH A. WILSON**, Forestry Sciences Laboratory, 2500 South Pine Knoll, Flagstaff, Arizona 86001, USA.

BOLITOGLOSSA RUFESCENS (Northern Banana Salamander) **PREDATION**. While predation on small ectotherms by mantids has previously been documented (Wright 1982. N. Terr. Nat. 1(5):10–11), accounts of predation on salamanders are conspicuously scarce from the literature. The following is an account of an attack by an adult mantid, *Choeradodis strumaria*, on an adult salamander, *Bolitoglossa rufescens*. The observation was made on 10 July 1993 at ca. 2230 h at the University of México's Estacion de Biologia "Los Tuxtlas" in southern Veracruz, México.

As I observed a pair of *B. rufescens* ascend a concrete wall during a rain shower, an adult *C. strumaria* landed on the wall ca. 1 m above the salamanders. After a few seconds the mantid began walking rapidly down towards the still ascending pair and stopped ca. 0.5 m above them directly in their path. When one of the salamanders was within range, the mantid tried unsuccessfully to grasp it. Following the initial attack, both salamanders stopped and remained motionless. Within 5 s the mantid attacked a second time and was once again unsuccessful. The salamander that had been attacked turned around and began crawling down the wall away from the mantid. The mantid pursued the salamander and on the third attack was successful in grasping it. The salamander immediately began writhing violently and the pair fell onto the concrete sidewalk beneath the wall. The pair struggled for ca. 1 min before the salamander became motionless. The mantid began to feed on the salamander at a point just posterior of the left eye. After ca. 1 min the salamander started struggling once more. The apparently weakened salamander was unable to free itself from the mantid. Following ca. 1–2 min of struggling, the mantid released the salamander and quickly flew off into the forest. After it was released, the salamander remained motionless on the sidewalk for ca. 10 min before any movement was noticed. Upon capture and examination, one small wound was visible immediately behind the left eye but otherwise the salamander appeared unharmed. After release at the site of the incident, the salamander rapidly ascended to the roof.

While no other attacks of this nature were observed over a period of 10 weeks, mantids and salamanders were frequently observed in close proximity on the concrete wall of the Estacion's buildings, particularly during rain showers. Based on this observation, it is possible that mantids may be successful in catching, subduing, and consuming salamanders. It appears, however, that prey handling costs may be relatively high and this was an isolated occurrence.

I would like to extend my gratitude to Wyatt Hoback for his assistance in identifying the mantid and thank Richard C. Vogt for logistical support during my stay in Veracruz. Funding for my work at the Estacion de Biologia was provided out of pocket.

NECTURUS MACULOSUS (Mudpuppy). **REPRODUCTION**. During a snorkel survey at the Larsen Road bridge crossing of the Namekagon River, Sawyer Co., Wisconsin, USA (T42N, R8W, Sec. 21) on 13 August 1991, I found an adult mudpuppy with at least 15 striped juveniles beneath a rock slab 1 m from shore in a side channel upstream from the bridge. This observation, in conjunction with a similar sighting at the same locality on 16 September 1982 (Cochran and Lyons 1985. Herpetol. Rev. 16:53, with the location mistakenly listed as Sec. 16), provides an indication of the range in phenological timing of mudpuppy reproductive events that might be encountered at a given site. Whether variability in timing within years is as extensive as that observed in this case between years is debatable. Some workers (Fitch 1959. Copeia 1959:339–340, and references therein) have suggested that the period of spawning is brief because embryos from different nests in the same location are usually at similar stages of development.

I thank Joe Cochran for assistance with the snorkel survey.

Submitted by **PHILIP A. COCHRAN**, Division of Natural Sciences, St. Norbert College, DePere, Wisconsin, 54115, USA.

PLETHODON ALBAGULA (Western Slimy Salamander.) **FOOT ANOMALIES**. Six of 10 (60%) slimy salamanders, MCZ 119267–76, collected 13 March 1994 ca. 1.5 km NE of Driftwood, Hayes Co., Texas, USA, have apparent developmental anomalies of feet or toes. Some have more than one affected foot (20% of all 40 feet). Anomalies vary from palmation and syndactyly to a double manus (Fig. 1). Of the four normal individuals, two are apparently young of the year, 23 and 28 mm SVL. The habitat appears natural, with no sources of pollution. Bear Creek flows within 20 m of the site, is clear, and heavily used for recreation. Slimy salamanders are abundant at this site.

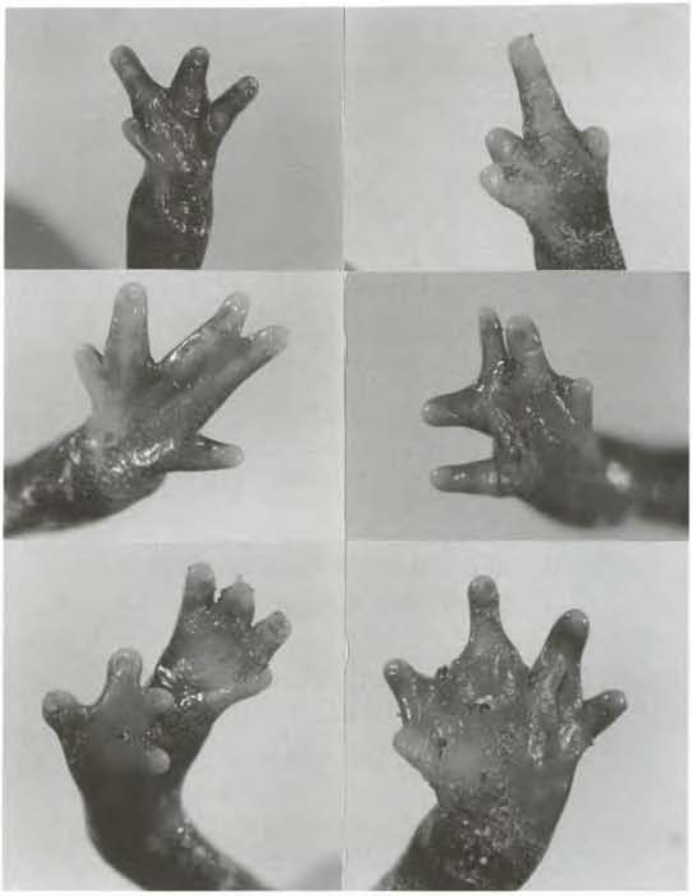

FIG. 1. Foot anomalies in *Plethodon albagula* from Hayes Co., Texas.

Of 84 other MCZ specimens of *P. albagula* from other sites in Hayes, Comal, and Travis counties, none shows comparable anomalies. Some are missing toes: eight individuals (9.5%); one has two affected feet. These anomalies appear to be the result of trauma rather than developmental. One (MCZ 117600) from Austin, Travis Co. has a rectangular heel protuberance on the right pes. The number of unusual salamanders among these 84 is 10 (11.9%) with 11 abnormal feet (3.3%). The difference, compared to MCZ 11267-76, is significant (Chi square). I am indebted to Thomas Sinclair for collecting the specimens.

Submitted by **JAMES LAZELL**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835, USA.

PLETHODON CINEREUS (Eastern Red-backed Salamander) **NEST BEHAVIOR**. Female *P. cinereus* suspend their eggs in moist cavities within and under rotting logs and stumps on the forest floor (Gilhen 1984. Amphibians and Reptiles of Nova Scotia. Nova Scotia Museum, Halifax, 64 pp.). Each female then remains with her eggs during their direct development (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Co., New York, 670 pp.).

Amphibian surveys were conducted in hardwood forest stands just outside the northern park boundary of Fundy National Park, Sussex, New Brunswick, Canada on 6 August 1994 (45°40'N; 65°09'W) and 19 August 1994 (45°41'N; 65°05'W). The goal of the research was to identify and count the number of species and individuals of each species in a 100 m^2 plot and to release the amphibians unharmed. During these two surveys a total of nine *P. cinereus* nests were discovered. Seven of the nests were found in logs, while the other two were located in stumps. One log contained three nests, but they were not located near one another. During the second survey (19 August) young *P. cinereus* were observed prematurely hatching from their eggs due to the disturbance caused during the search. These newly hatched young still retained yolk sacs in their stomachs. Several previously hatched young were also present, and did not contain yolk sacs. It is common for the young to stay near the nest after they hatch for up to three weeks (Sayler 1966. Copeia 1966:183–193). The number of eggs and/or young per nest ranged from 1–14 (a few young may have escaped detection). Gilhen (*op. cit.*) reported that *P. cinereus* females in Nova Scotia produce 4–17 eggs. Sixty-six percent (N = 6) of the nests observed had 8 or more eggs and/or young. When disturbed, the young immediately tried to escape. The newly hatched young were ca. 1 cm SVL and 0.5–1.0 cm tail length.

In general, *P. cinereus* are territorial and aggressive towards members of their own species (Duellman and Trueb, *op. cit.*). Therefore, it was surprising to note at 8 of the 9 nests two adult salamanders were in attendance, while at the remaining nest only one adult was observed. In all 8 cases where two adults were present, both adults were either in contact with, or in close proximity to, the eggs and/or young This observation conflicts with previous reports of only one adult, the female, brooding or guarding the eggs (Duellman and Trueb, *op. cit.*; Highton and Savage 1961. Copeia 1961:95–98; Sayler, *op. cit.*). If indeed one of the individuals was the brooding female, it is possible the other adult

was a male rather than a second female. This may be supported by the behavioral observations of Highton and Savage (*op. cit.*) who found that brooding *P. cinereus* females chase neighboring females away from their nest. They also reported that neighboring females will eat the brooding female's eggs. Aggressive interactions between both individuals present or predation of eggs by either one of the individuals was not observed. *Plethodon cinereus* is sexually dimorphic with males tending to have smaller total body lengths than females (Gilhen, *op. cit.*). At five of the nests one adult was larger in total body length than the other individual, while at three nests both adults were approximately the same size. More detailed examination of specimens would have been necessary to confirm sexes.

On one other occasion (19 June 1991), in Halifax Co., Nova Scotia (44°31'30"N; 63°45'30"W) two adult *P. cinereus* were found at a nest under a rotting stump.

I thank R. Waldick and B. Freedman for the use of some of these behavioral data which were collected while the author was working for them as part of the Greater Fundy Ecosystem Project. I would also like to thank R. Wassersug and E. Coscia for helpful suggestions on this manuscript.

Submitted by **STEPHEN C. FRIET**, Department of Biology, Dalhousie University, Life Sciences Centre, Halifax, Nova Scotia B3H 4JI, Canada.

PLETHODON CINEREUS CINEREUS (Redback Salamander). **COLORATION.** A single erythristic phase *Plethodon c. cinereus* was captured in a drift-fence array located in Great Pond Township of Hancock Co., Maine, USA, on 10 September 1993; four others were captured in a similar array in LaGrange Township, Penobscot Co. from 15 June to 31 July 1994. The salamander captured in Hancock Co. was located in a stand of mature hemlock (*Tsuga canadensis*) and yellow birch (*Betula alleghaniensis*); the animals from Penobscot Co. occurred in a northern hardwood stand (*Fagus grandifolia* and *Acer saccharum*). A softwood dominated forest stream passed within 150 m of the drift-fences at both sites.

The specimens were brick red dorsolaterally with black flecks spread evenly across the body, including on the head and legs. The density of flecks on the tail increased to produce a mottled appearance of equal parts of black and red. Ventrally, the throat was mostly creamy white and the belly was mottled with cream and slate grey. The single specimen from Hancock Co. was 42 mm SVL, sex unknown. Two females from Penobscot Co. were 46 and 44 mm SVL; two others were 44 mm SVL, sex unknown. A total of 9 redback salamanders were captured during the summer of 1993 at the softwood-dominated Hancock Co. site. The frequency of redback to scarlet phase individuals was 8:1. The Penobscot Co. array yielded 157 redback salamanders with a redback to scarlet phase ratio of 38.3:1.

Plethodon c. cinereus is the only salamander species in New England to exhibit color pattern polymorphism with three distinct color phases: the red-striped, the grey, and the scarlet or erythristic phase. The rarest of the three color morphs is the erythristic phase which is previously unreported from Maine. The evolutionary basis for color pattern polymorphism in this species is poorly understood but see Lotter and Scott (1977. Copeia 1977:681–690) and Tilley et al. (1982. Herpetologica 38:409–417) for a discussion and experimental test of the hypothesis that erythristic individuals might be Batesian mimics of red efts (juvenile *Notophthalmus viridescens*).

Submitted by **PHILLIP G. DEMAYNADIER**, Department of Wildlife Ecology, Nutting Hall, University of Maine, Orono, Maine 04469, USA.

PLETHODON IDAHOENSIS (Coeur d'Alene Salamander). **PREDATION.** Little is known about predation on terrestrial salamanders. On 16 June 1993, a partial carcass (Fig. 1) of *Plethodon idahoensis* (ca. 51 mm SVL, ca. 44 mm TL) was discovered under a rock (< 20 cm diam) alongside an unnamed creek which flows into the south end of Beauty Bay, Coeur d'Alene Lake, Kootenai Co., Idaho, USA (T49N, R3W, NE1/4 of section 11). The head, vertebral column, tail, and the left fore and hind limbs composed the carcass (Fig. 1). The tail was undulating at the time of collection (1230 h) and was still moving 3 h later when preserved in 10% NB formalin. The lack of an obvious mental gland suggests it was a female.

The only observed predator of *P. idahoensis* is the western robin, *Turdus migratorius;* a robin carried an individual *P. idahoensis* to another site before attempting to consume it (Wilson and Simon 1985. Herpetol. Rev. 16:111). Discovery of the carcass under a rock, however, suggests an attack by a ground-dwelling predator such as a shrew or an invertebrate, rather than a bird. In the field, carabid beetles have been observed consuming the soft parts of frogs (Robertson 1989. Herpetol. Rev. 20:7–8) and salamanders, e.g., *Ambystoma jeffersonianum* (Smith 1946. Herpetol. 3:67) and *Plethodon vehiculum* (Ovaska and Smith 1988. Can. J. Zool. 66:599–604). In the lab, carabid beetles (*Scaphinotus* and *Pterostichus*) consumed *Plethodon vehiculum,* but chose individuals much smaller (< 26mm SVL) than the *P. idahoensis* reported here (Ovaska and Smith 1988, *op. cit.*). *Scaphinotus* occurs in the same habitat as *P. idahoensis* (Wilson, pers. comm.). It is unknown whether the predator subdued this salamander or whether the salamander was moribund prior to the attack. The undulating tail suggests the animal was alive when first attacked.

The carcass will be deposited in the Charles R. Conner Museum at Washington State University, Pullman. I thank John H. Larsen, Jr. for commenting on the manuscript. Field work was supported by the Murdock College Science Research Program.

FIG. 1. Carcass of an adult *Plethodon idahoensis* found under a rock.

Submitted by **NANCY L. STAUB**, Biology Department, Gonzaga University, Spokane, Washington 99258, USA.

PSEUDOEURYCEA CEPHALICA MANNI (NCN). **REPRODUCTION.** Among the 26 species of salamanders of the genus *Pseudoeurycea* ocurring in México (Flores Villela 1993. Carnegie Mus. Nat. Hist. Spec. Publ. (17):1–73), data on reproduction exist for only seven species: *P. expectata* (Stuart 1954. Proc. Biol. Soc. Washington 67:159–178; Salthe 1963. J. Morphol. 113(2):161–171); *P. belli* (Duellman 1961. Univ. Kansas Publ. Mus. Nat. Hist. 15:1–148); *P. nigromaculata* and *P. juarezi* (McDiarmid and Worthington 1970. Herpetologica 26:57–70); *P. brunnata, P. goebeli*, and *P. rex* (Houck 1977. *In* Taylor and

Guttman [eds.]., The Reproductive Biology of Amphibians, pp. 43–72. Plenum Press, New York). According to Duellman and Trueb (1986. Biology of Amphibians. McGraw-Hill. 670 pp.), *Pseudoeurycea* has internal fertilization, terrestrial eggs, and direct development.

On 30 March 1990, we collected an adult female *P. cephalica manni* (MZFC 5988, 47.7 mm SVL, 82.4 mm TL, 3.0 g) 2 km NW Palo Gacho, Municipality of Tenango de Doria, Hidalgo, México, 2300 m elevation, in a pine-oak forest. The specimen was found under a rock (Fig. 1) with 28 eggs in a gelatinous mass that measured 18.2 mm (largest diameter) and weighed 1.3 g. The eggs were elliptical in shape, with an average length of 4.5 mm (SD = 0.335; range = 3.9–5.0 mm) x 4.0 mm (SD = 0.233; range = 3.5–4.7). Some eggs were in late gastrulation stages 9 and 10 (Duellman and Trueb, *op. cit.*).

The specimen was found under a rock, coiled about the clutch in a depression, as recorded for *P. juarezi* (McDiarmid and Worthington, *op. cit.*) and *Nototriton barbouri* (McCranie and Wilson 1992. Herpetol. Rev. 23:115–116).

FIG. 1. Adult female *Pseudoeurycea cephalica manni* (MZFC 5988) with clutch of eggs.

When we tried to collect the female, she secreted a substance on the skin and undulated her tail and body. This behavior has already been reported in the genus *Pseudoeurycea* and is common in almost all species of salamanders (Duellman and Trueb, *op. cit.*).

We thank Hobart M. Smith, Oscar Flores, and Aurelio Ramírez for reviewing the manuscript, and Mario Mancilla Moreno for the photograph. Sol de Mayo Mejenes López prepared the photographic print for publication. This work was supported by the Direccion General de Asuntos al Personal académico (DGAPA) project IN-201789 and project PADEP 003001.

Submitted by **FERNANDO MENDOZA QUIJANO** and **EFRAIN HERNANDEZ GARCIA**, Museo de Zoología, Facultad de Ciencias, UNAM, Apdo. Post. 70-399, México, D.F., México.

ANURA

AGALYCHNIS CALCARIFER (NCN). **REPRODUCTION**. *Agalychnis calcarifer* (Hylidae) is a large neotropical frog that breeds in puddles formed on fallen logs in lowland rain forests of Central and South America (Donnelly et al. 1987. Copeia 1987:247–250; Duellman 1970. Monogr. Mus. Nat. Hist. Univ. Kansas 1:1–753). As part of a larger study of arboreal egg-laying frogs, I and several volunteers observed the breeding biology of *A. calcarifer* during 18 months between 1989 and 1992. We made these observations at La Selva Biological Station, Heredia Province, Costa Rica in lowland (35–185 m) wet tropical forest. Rainfall averages approximately 400 cm per year, and the rainy season occurs between May and December. Four breeding sites, all in pan holes between the buttresses of fallen trees, were used repeatedly by ovipositing *A. calcarifer*. Adults were observed amplecting and egg-laying on 9 August and 5 September 1991 at one site, and on 10 August 1991 at another site. The following sequence was recorded for egg-laying on the morning of 9 August 1991.

0930 h: Pair in amplexus on log.
0945 h: Frogs entered water in log puddle and swam 2.3 m.
0948 h: Female moved out of water and positioned vent ca. 7 cm vertically above the surface of the water on log.
0951 h: Female's abdomen contracted and male positioned his vent parallel to female's.
0952 h: Male bobbed his head once quickly. His lower jaw came in contact with the top of the female's head.
0953 h: Female began ovipositing.
0955 h: Female moved ca. 3 cm away from egg mass.
0956 h: Male climbed to top of female's head. Male moved off female and onto log. Female dropped back into water on log. By 1020 h the male had jumped off the log out of view and the female was still sitting in the water. Observations ended.

During the three times that egg-laying was observed, females took 3, 9, and 10 minutes each to complete ovipositing. Amplecting animals were already paired when first sighted, thus total duration of amplexus is not known.

Agalychnis calcarifer bred in pan holes that were also used by other anurans. Adults of *Leptodactylus melanonotus* and *Eleutherodactylus crassidigitus* (both Leptodactylidae) were found in or near the water pools at several sites. An adult female *Smilisca phaeota* (Hylidae) was found at one site the morning after many small floating hylid eggs were found at this site.

I thank David Roberts and James Murphy of the Dallas Zoo for their careful observations.

Submitted by **WENDY E. ROBERTS**, Museum of Vertebrate Zoology and Department of Integrative Biology, University of California, Berkeley, California 94720, USA.

ATELOPUS ZETEKI (Panamanian Golden Frog). **PURE TONAL VOCALIZATION**. Males of the genus *Atelopus* produce three general call pattems: the pulsed call, the pure tonal whistle, and the short call (Cocroft et al.1990. Copeia 1990:631–643; Crump 1988. Anim. Behav. 36:1064–1077; Jaslow 1979. J. Herpetol. 13:141–145; and Lescure 1981. Bull. Mus. natn. Hist. nat., Paris 3:893–910). The pulsed vocalization appears to function primarily as male advertisement to conspecifics, and secondarily as a dominance signal during bouts of aggression (Cocroft et al., *op. cit.*; Crump, *op. cit.*; and Jaslow, *op. cit.*). There is no evidence that vocalizations play a role in female attraction. Pulsed calls may be used in mate attraction by males of two South Ameri-

can atelopids, *A. pulcher* (= *A. spumarius*) and *A. flavescens* (Jaslow, *op. cit.*; and pers. obs). The short call is produced by most species when seized by a potential predator or in crowded captivity (Jaslow, *op. cit.*; Cocroft et al., *op. cit.*). Also, I have witnessed two species from Panama, *Atelopus* sp. from Nusagandi, San Blas, [likely the same *Atelopus* sp. referred to by Savage (1972. Herpetologica 28:77–94) and Cocroft et al. (*op. cit.*) and *A. chiriquiensis*, from Cerro Punta, Chiriqui, using the short call during conspecific wrestling bouts. These calls are given by the individual being attacked. Crump (*op. cit.*) reported similar behavior in *A. varius*. The pure tonal whistle has been documented in *A. cruciger, A. minutulus*, and *A. chiriquiensis*. This whistle is used by the inferior male *A. chiriquiensis* after losing an aggressive confrontation (Jaslow, *op. cit.*).

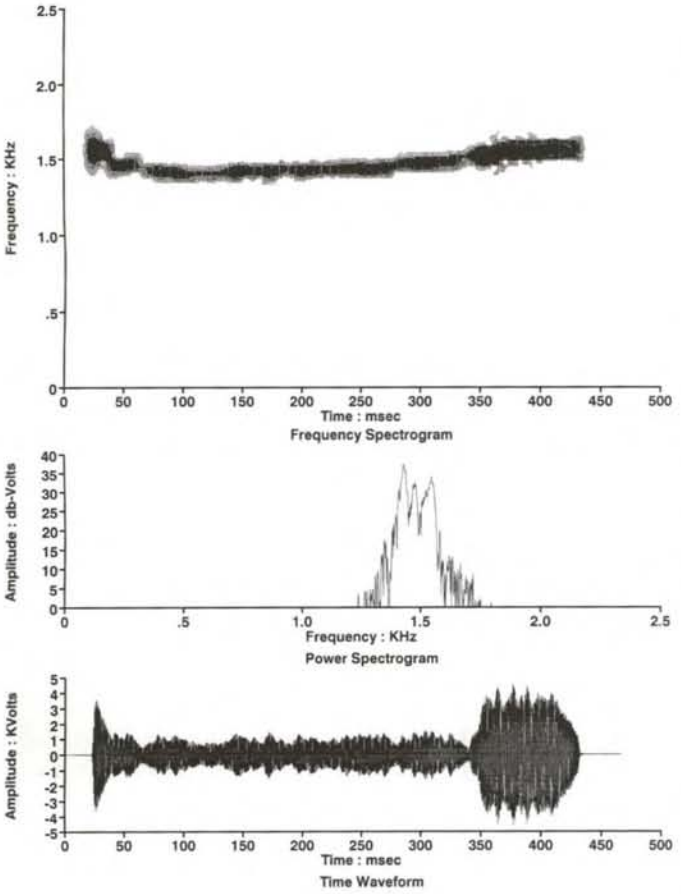

FIG. 1. Frequency Spectrogram (top), Power Spectrogram (middle), and Time Waveform (bottom) for 1 of 3 recorded pure tonal whistles in *Atelopus zeteki*. The frequency spectrogram was calculated at 256/2000 (FFT points/FFT steps), with a bandwidth of 39.1 Hz. The power spectrogram was calculated at 8192 FFT points, with a bandwidth of 1.2 Hz. All calculations and graphs in Figure 1 were produced using Signal© (Beeman 1993. Signal User Guide, vers. 2.2, Engineering Design. Belmont, Massachusetts).

During March 1994 in Panama, I recorded *A. zeteki* males vocalizing in an outdoor terrarium at El Valle de Anton, Provincia de Cocle, using a Sony TCD-D10 PRO Digital Audio Tape-corder via an Audio-Technica 815a directional microphone. During this recording, one male changed from a pulsed call to a tonal whistle, a vocalization not previously documented for this species. The male was neither being agitated by me nor another frog. During an experimental trial in July 1994 another male was observed using pure tonal whistles in response to playbacks of male pulsed vocalizations. No sound recordings were made during the observation period. I suspect that whistles performed during this playback experiment may have been pre-confrontational surrender to a perceived potential aggressor.

The tonal call of *A. zeteki* is lower in frequency than the pulsed and short types and is frequency modulated. There is an initial downward frequency sweep followed by a more gradual upward sweep. The pure tone has a mean maximum frequency of 1660 Hz ± 17.3 and a mean minimum frequency of 1390 Hz ± 0 for the three calls recorded. The mean peak frequency was 1556.7 Hz ± 90.2 and duration varied between 386 and 468 msec. Recordings have been deposited and catalogued (BLB-20404/EL9401D) in the archives of the Borror Laboratory of Bioacoustics at The Ohio State University.

I especially am thankful for the help of David W. Swihart, Thomas E. Hetherington, A. Stanley Rand, Roberto Ibanez, Sandra L. L. Gaunt, Hitesh Khanna, and Molly A. Lindquist. Financial support was provided through a Smithsonian Tropical Research Institute short-term fellowship. Call analysis was done at the Borror Laboratory of Bioacoustics.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). **PREDATION**. *Osteopilus septentrionalis* is an introduced species presently expanding its range in the peninsula of Florida. It is an aggressive feeder upon insects and smaller native treefrogs (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida, Part Three, The Amphibians. Windward Publishing, Inc., Miami, Florida. 191 pp.), while noxious skin toxins presumably afford it protection against some local predators. An instance of *O. septentrionalis* being ingested as the prey of a native Florida snake, without apparent discomfort to the predator, is documented here.

FIG. 1. *Thamnophis sauritus sackenii* swallowing the head of an *Osteopilus septentrionalis* that was eaten rear feet first.

On 18 February 1994, I investigated an anuran distress call in the vicinity of the front door of my home (4 km E of Alva, Lee Co., Florida, USA) at 1055 h on a humid overcast morning. Entwined among the exotic foliage climbing the house, about 1 m above ground level, was a ca. 60 cm TL peninsula ribbon snake (*Thamnophis sauritus sackenii*) grasping the ends of both rear legs of a ca. 4 cm SVL *O. septentrionalis* (Fig. 1). The snake seemed not to be bothered by any aspect of the frog as it took 15 minutes to completely swallow it. Several slides taken within close proximity failed to disturb the situation. The air temperature was 23.1°C.

At 1205 h, the snake was still resting in the same basic position with the slight bulge located in the middle of its length, confirming that the frog was not regurgitated within the first hour. This suggests that the spread of *O. septentrionalis* in Florida will meet some resistance as at least one native snake species is capable and willing to utilize them as food.

PELTOPHRYNE GUENTHERI (NCN). **DIET**. Although aspects of ecology were summarized by Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville), the diet of *Peltophryne guentheri* has not been described. This endemic toad occupies largely xeric lowland habitats throughout Hispaniola. Stomachs taken from 204 individuals (90 juveniles, 65 adult females, and 49 adult males), collected during various months from a variety of locations on Hispaniola, were examined. Adult status was determined by the presence of eggs in females and enlarged testes in males.

TABLE 1. Stomach contents of *Peltophryne guentheri* from Hispaniola.

Contents	Number	Volume	Frequency	Importance
Arachnida Araneae	15	0.653	7	0.157
Coleoptera	136	1.953	53	0.739
Coleoptera (immature)	128	0.538	13	0.276
Dictyoptera	2	0.035	2	0.019
Diptera	4	0.010	3	0.023
Hemiptera	8	0.063	7	0.058
Homoptera	4	0.023	4	0.030
Homoptera (immature)	22	0.230	1	0.062
Hymenoptera (Formicidae)	636	1.645	59	1.176
Hymenoptera (Formicidae immature)	3	0.050	1	0.016
Hymenoptera other	10	0.568	8	0.133
Isoptera	127	0.190	2	0.156
Lepidoptera (immature)	5	0.135	3	0.043
Orthoptera	9	0.368	9	0.118
Plecoptera	1	0.005	1	0.008
Arthropod parts (unidentified)	—	0.055	16	
Nematoda	6	0.008	3	
Plant material	—	1.773	49	
Grit	—	0.153	8	

Prey was present in the stomachs of 105 individuals (empty stomachs were likely attributable to specimens collected early in the evening before feeding had commenced). Stomach contents were analyzed and arthropods were identified to order and counted. Volumes of all food items were determined using fluid displacement methods of Milstead (1957. Texas J. Sci. 9:410–447). Ants were present in the greatest number (636 of 1109 food items) and were found in the most stomachs (59). Adult beetles constituted the greatest volume (1.95 of 6.34 cm^3 total prey volume) and were found in 53 stomachs. Eight stomachs contained grit and 49 contained plant matter (ingestion of which was presumably adventitious). Results are summarized in Table 1.

No significant differences (Wilcoxen signed-rank test) existed between the diets of males and females ($Z = -1.14$, $P = 0.26$) or between those of adults and juveniles ($Z = -1.08$, $P = 0.28$). Snout-vent length was positively correlated with mean prey size (Spearman rank correlation, $Z = 3.95$, $P < 0.01$).

Importance values (Powell et al. 1990. Carib. J. Sci. 26:67–70) were used to calculate Levin's measure of niche breadth (Krebs 1989. Ecological Methodology. Harper & Row). A calculated breadth of 0.61 suggests that *Peltophryne guentheri* is a dietary generalist despite the prevalence of ants and beetles in the stomachs examined.

I thank Robert Powell for access to specimens in the Bobby Witcher Memorial Collection, Avila College, and William E. Duellman and John E. Simmons for permission to examine specimens in the Albert Schwartz Field Series, University of Kansas Museum of Natural History.

Submitted by **KEELY J. PARSONS**, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145, USA.

RANA CAPITO (Gopher Frog). **COMBAT**. The occurrence of male-male combat in ranid frogs was summarized by Wells (1977. Anim. Behav. 25:666–693) and Shine (1979. Copeia 1979:279–306), where *Rana catesbeiana* and *R. clamitans* were listed as North American ranids known to participate in male-male combat. Howard (1980. Anim. Behav. 28:705–716) subsequently reported male-male combat in *R. sylvatica*. The following observation describes a bout between two gopher frogs (*Rana capito*), a species not previously reported to engage in male-male combat.

The episode took place at an ephemeral pond in Harrison Co. in southeastern Mississippi, USA, during the night of 4 March 1988. The two frogs were engaged in the behavior upon their discovery. The frogs were facing each other on the pond bottom, at a depth of ca. 35 cm. Both frogs exhibited three types of antagonistic actions toward one another: 1) head-butting, 2) pushing with the forelimbs, and 3) kicking with the hindlimbs. During the struggle the frogs often appeared to close their eyes, and their nictitating membranes covered the eye throughout. Several times the frogs became separated and turned away from one another, but always returned to face each other. The episode lasted three minutes from the time they were discovered, and each frog surfaced at least one time during the bout, presumably for air. Upon reaching the surface, the frog would immediately turn and swim back toward the other frog on the pond bottom. The frogs seemed undisturbed by flashlight, until one surfaced directly facing the beam and then disappeared under grass on the pond bottom. Only one of the frogs was captured and positively identified as a male, but the other was similar in size and its behavior was aggressive. Heavy rains occurred in the 24 hour period prior to the episode, and coincided with the time period in which deposition of gopher frog egg masses was observed.

Wells (*op. cit.*) described behavior typically associated with male-male combat in frogs. Because our (GNJ) observations

closely follow those he summarized, we believe this account documents that male-male combat exists within the mating system of *R. capito*.

Submitted by **J. SEAN DOODY, JEANNE E. YOUNG**, Department of Biological Sciences, Southeastern Louisiana University, Box 814, Hammond, Louisiana 70402, USA, and **GLEN N. JOHNSON,** Southern Forest Experiment Station, 1925 Thirty-fourth Street, Gulfport, Mississippi 39501, USA.

RANA PRETIOSA (Spotted Frog). **BASKING BEHAVIOR.** On 16 April 1993, a male *Rana pretiosa* (60 mm SVL) was perched horizontally on a dead cattail (*Typha* sp.) leaf about 30 cm above the water in a 0.2 ha marsh 1 km north of Charleston, Wasatch Co., Utah, USA. Air and water temperatures were 18.5°C and 13.5°C, respectively. The frog was in full sunlight from 1350 until 1415 h when we captured it to obtain measurements. This observation is noteworthy given the aquatic habits of *R. pretiosa* (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press. Moscow, 332 pp.). Several *R. pretiosa* at this site had leeches (*Helobdella stagnalis*; P. Hovingh, pers. comm.), although the individual we observed did not. Basking also may increase growth rates, but there may be other unknown advantages conferred to the animal (Freed 1980, Physiol. Zool. 53:433–444). We thank P. S. Corn and P. Hovingh for suggestions regarding this note.

CROCODYLIA

CAIMAN LATIROSTRIS (Broad-snouted Caiman). **NESTING.** Although *Caiman latirostris* is widely distributed in southeastern South America (Medem 1983. Los Crocodylia de Sur America. Vol. 2. Ed. Carrera, Bogota. 270 pp.), the reproductive biology of the species remains poorly known (Thorbjarnarson 1992. Crocodiles: An Action Plan for their Conservation. Gland, Switzerland: IUCN). *Caiman latirostris* is considered an endangered species due to habitat destruction and over exploitation (Groombridge 1987. *In* Webb et al. (eds.), Wildlife Management: Crocodiles and Alligators, pp 9–21. Surrey Beatty and Sons Pty. Ltd., Sydney), hence information about all aspects of its reproductive biology is needed to formulate plans for the species' conservation. In this note we present data on nest characteristics, clutch size, and egg size from eight nests found on floating grass mats.

This study is part of an environmental impact study carried out by Companhia Energética de São Paulo (CESP) in the area to be inundated by Porto Primavera Dam, Paraná River, on the border between São Paulo and Mato Grosso do Sul states. The surveys were conducted between parallels 20°48' and 22°30'S. Nests were located by flying over the floodplains of the Paraná River and tributaries in a Bell 206 helicopter on 1 February 1993 and 25 February 1994. Studies on reproductive ecology of *C. latirostris* have been hindered mainly because it is difficult to locate their nests. However, searching from the air facilitated finding nests on floating grass mats. We spent about 30 minutes/flight to locate each nest. Aerial surveys of nests are frequently used in studies of crocodiles and alligators (e.g., Webb 1987. *In* Webb et al. (eds.), *op. cit.*, pp. 107–124; Joanen and McNease 1989. Amer. Zool. 29:987–998). However, the technique has not been frequently used in South America (Campos 1993. J. Herpetol. 27:127–132). Based on our experience, we recommend the use of helicopters to locate nests of *Caiman latirostris*.

TABLE 1. Sizes of broad-snouted caiman nests, eggs, and embryos from the area to be inundated by the Porto Primavera Dam. Nests 1–5 were found in January 1993, and nests 6–8 during February 1994. LE = mean egg length, WE = mean egg width, and SD = standard deviation.

#	nest			eggs			embryos	
	length (cm)	width (cm)	height (cm)	number	LE ± SD (mm)	WE ± SD (mm)	length (mm)	age (days)
1	150	150	—	—	—	—	65	19
2	108	105	52	24	74 ± 3	41 ± 2	160	35
3	120	110	40	17	63 ± 2	41 ± 1	73	21
4	102	100	40	24	67 ± 3	44 ± 1	123	32
5	98	95	45	33	68 ± 2	44 ± 1	140	33
6	102	100	45	23	64 ± 4	40 ± 1	220	60
7	135	111	50	22	69 ± 4	40 ± 1	198	45
8	113	100	40	8	72 ± 2	42 ± 1	210	58
mean	116.0	108.9	44.5	21.6	68.4	42.4	148.6	37.9
SD	18.2	17.5	4.9	7.6	4.5	1.9	59.6	15.4

We inspected five nests of *C. latirostris* in 1993 and three nests in 1994. The nests were located on floating grass mats dominated by *Cyperus prolixus* and *Scirpus cubensis*. Other common macrophyte species were *Cyperus surinamensis, Setaria geniculata*, and *Habernaria* sp. We measured the height, length, and width of each nest, and counted and measured the eggs. We also removed one egg from each nest and measured the total length of the embryo. We used Crawshaw's table (1989. Nesting Ecology of the Paraguayan Caiman (*Caiman yacare*) in the Pantanal of Mato Grosso, Brazil. Unpubl. M.S. Thesis, Univ. Florida, Gainesville), developed for *C. crocodilus yacare*, to estimate the age of the egg from the size of the embryo.

Females were present at two nests. Nests contained 8–33 eggs, but the nest with 8 eggs was partially inundated. The mean clutch size overall was 21.6, and excluding the partially inundated nest it was 23.8 eggs (N = 6, SD = 5.2) (Table 1). The estimated age of embryos indicates that laying occurred in late December, while hatching occurred during early March in both years. The clutch sizes found in this study were smaller than those reported in earlier studies (Larriera 1993. *In* Verdade et al. (eds.) Proceedings of the 3rd Workshop on Conservation and Management of the Broad-nosed Caiman, pp 61–69. ESALQ/USP, Piracicaba, Brasil). This is the first report of *C. latirostris* nesting on floating grass mats.

We thank V. Pott for identifying the plants, and M. Cotovicz and E. Dantas for helping in the field.

TESTUDINES

GOPHERUS POLYPHEMUS (Gopher Tortoise). **BURROW ASSOCIATE.** The burrow system created by *Gopherus polyphemus* plays an important part in the ecology of the upland ecosystem, providing shelter from extreme temperatures, light, fire, aridity, and predation. Jackson and Milstrey (1989. *In* J. E. Diemer et al. (eds.), Gopher Tortoise Relocation Symposium Proceedings. Florida Game and Fresh Water Fish Commission Nongame Wildl. Prog. Tech. Rpt. No. 5:86–98) list 362 species recorded from *G. polyphemus* burrows (60 vertebrates and 302 invertebrates). In this note we report a previously unrecorded species utilizing burrows.

A *Lampropeltis getula* (common kingsnake) entered an active adult *G. polyphemus* burrow on 22 May 1990 at Tenoroc State Reserve located approximately 4 km NE Lakeland, Polk Co., Florida, USA. The female snake (SVL = 97 cm, TL = 109.4 cm) was trapped using a double-opening funnel trap (Fitch 1951. Herpetologica 7:77–80), sexed, measured, marked, photographed, and released.

On 16 May 1991, during a *G. polyphemus* burrow associate survey at the same location, a male *L. getula* (SVL = 129 cm, TL = 137 cm) was trapped in a double-opening funnel trap at an abandoned subadult burrow and processed in the same manner.

Both specimens were caught at burrows associated with open, arid, reclaimed phosphate mined land. Burrows were located within 76 m of foraging habitat, extensive vegetative cover, and fresh water. The interburrow distance was 31.7 m.

We thank Joseph R. Casada and Steve DeCresie for assistance with fieldwork and the staff of Tenoroc State Reserve for logistical support. We also thank Richard Franz for reviewing the manuscript. This research was supported in part by a grant to LAM from the Florida Institute of Phosphate Research (#88-03-082) and was conducted under FGFWFC permit #W88052.

LACERTILIA

ANOLIS UNIFORMIS (NCN). **FEEDING BEHAVIOR.** Insectivorous lizards are often characterized as consuming prey that 1) require low pursuit and handling costs (Greene 1982, *In* D. Mossakowski and G. Roth (eds.), Environmental Adaptation and Evolution, pp. 107–128. Gustav Fischer, Stuttgart) and 2) are limited in size by lizard body size (Schoener 1968. Ecology 49:704–726). The maximum prey size for some insectivorous lizards may be best predicted by the circumference of the lizard's mouth (DeMarco et al. 1985. Copeia 1985:1077–1080). Some of my observations on *Anolis uniformis* feeding behavior are inconsistent with these characterizations, instead suggesting this species may regularly feed on prey requiring high handling costs and which are only partially consumed.

During May through July 1987, I conducted a field study on the ethology of *A. uniformis* at Los Tuxtlas Tropical Biological Preserve, Veracruz, México. During 59.5 h of focal animal observation, 18 feeding bouts were observed. The majority of these (15; 83%) involved small prey that were consumed whole. On three occasions, however, three different individuals attacked and consumed parts of much larger than average prey (all Diptera). These observations are interesting for two reasons. First, these lizards were not consuming prey whole and all of these insects appeared larger than the lizard's mouth circumference. In one instance, the head, prothorax, and one wing of a large Diptera were consumed. The length of the remaining part suggests this insect, whole, may have been inconsumable by the *A. uniformis*. In a second instance, half of the head capsule of another Diptera was consumed. Using the procedure of DeMarco et al. (*op. cit.*), this prey's circumference was roughly 2.9 times greater than the circumference of the predator's mouth. These lizards seemed to be performing behaviors promoting disarticulation of their prey. Constant mouth opening and closing occurred with the jaw at the juncture of the head and thorax of the flies. The lizards also wiped the insects against the substrate, resulting in wing removal and probably contributing to decapitation.

The second noteworthy aspect of these observations is that although only three of 18 (17%) *A. uniformis* feeding bouts involved large prey, they accounted for more than 94% of the observed handling time. The handling time in these three encounters lasted an average of 39.3 min (21, 37, 60 min), while none of the other 15 bouts lasted more than 10 sec.

For at least some insectivorous lizards, maximum prey size may be more properly related to the size of prey body regions and the ability to disarticulate prey; in such instances, the time devoted to prey handling may be substantial.

Submitted by **DOUGLAS A. EIFLER**, Department of Organismic and Evolutionary Biology, Harvard University, Cambridge, Massachusetts 02138, USA.

GEKKO CHINENSIS (Chinese Gecko). **SPIDER PREDATION**. On 8 August 1992 at the abandoned village of Kwo Lo Wan, island of Chek Lap Kok, South China Sea ca. 24 km west of Hong Kong, we discovered a young *Gekko chinensis* (SVL 56 rmm; 3.54 g damp weight, preserved) fresh-dead and silk-wrapped in the orb web of a large spider. Foolishly, we first collected the gecko (MCZ 177074), allowing the spider to escape into the tree canopy. Subsequently, we collected a second spider (MCZ A-13831) nearby. This spider, *Araneus ventricosus* (Araneidae), was equal in size to the one tending the web with the gecko (29 mm cephalothorax to abdomen tip; 2.45 g damp weight, preserved). This species was not as common as the larger *Nephila maculata* (Araneidae), a well-known predator of vertebrates as large as pipistrelle bats (Hill and Phillipps 1981. A Colour Guide to Hong Kong Animals, Government Printer, Hong Kong. 281 pp.). Sadly, the island of Chek Lap Kok has now been destroyed, flattened, and leveled to 2 m above sea level. I am indebted to Kerry Sherred and Robin Marirea for assistance in the field, and to Laura Leibensperger for identification of the spider.

Submitted by **JAMES LAZELL**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835, USA.

HEMIDACTYLUS FRENATUS (House Gecko). **FORAGING**. Though most reports of gecko diets, particularly those based on stomach contents analysis, mention only arthropods, geckos have been reported feeding on sap on the stems of plants (e.g., *Gehyra variegata* in Australia: Dell 1985. West. Austr. Nat. 16:69–70) and nectar from flowers (e.g., *Hoplodactylus pacificus* in New Zealand: Whitaker 1968. Science 11:623–651; *Phelsuma guimbeaui* on Maritius: McKeown 1989. Int. Zoo. Yearbk. 28:116–122). There are also reports of geckos lapping up man-made sweetened fluids (e.g., *Phyllodactylus*, Houston: Dell 1985, *op. cit.*) such as jam (e.g., *Leptodactylus lugubris*: McCoy 1980. Reptiles of the Solomon Islands. Wau Ecol. Inst. Handbk. No. 7.), and honey (e.g., *Heteronotia binoei*: Peters 1968. Aquarien Terrarien Zeitschrift 21:252–254). McCoy (*op. cit.*) reported seeing *Leptodactylus lugubris* "drinking the dregs in cups of sweetened tea and coffee." We report another gecko drinking from a rather different human provided source of sweetened liquid.

We observed several different *Hemidactylus frenatus* feeding from a hummingbird feeder in Panama. The feeder was filled with a clear solution of refined sugar (1 part sugar to 7 parts water) and regularly visited by several species of hummingbirds during the day. The feeder was suspended from a bracket outside an apartment window, 22 cm from the wall and 4 m above the ground. The introduced geckos are abundant in Panama, almost entirely around human habitations. On the Smithsonian Tropical Research Institute building where these observations were made, it is common to see one or two adult-sized geckos on a single 75 by 90 cm window.

Geckos were observed for the first time at the feeder less than 3 weeks after its installation. We observed geckos on the feeder most nights during the period from October to December. At least 4 individuals, 1 large, 2 medium, and 1 juvenile were seen on the feeder, and probably more visited it (Fig. 1). Aggressive behaviors (chases and growl calls) like those observed when two geckos came close to one another on a window screen usually occurred when two geckos were together on the feeder.

In early January the feeder was moved to another window 6 m away horizontally and a floor (3 m) higher. Over the following months, no geckos were seen on the feeder, though they were observed feeding on insects on the window screens near it. Perhaps feeding at the hummingbird feeder was a case of social facilitation. A single gecko may have discovered the feeder in its original position and others, seeing the first feed there, approached and imitated it. Six months after the feeder was moved, a few individuals apparently learned to feed from it, and were regularly seen on the feeder.

Geckos, like anoles, commonly lap droplets of water from leaves and twigs (Cogger 1958. Aust. Mus. Mag. 1211:343–347). We do not know if the geckos we observed were seeking water or carbohydrates from the feeder but they were certainly consuming both. That the geckos visited the feeder during the height of the rainy season when water was easily available elsewhere, suggests they were seeking food rather than water.

The close association of *Hemidactylus frenatus* with humans in Panama is striking. They use human structures for foraging surfaces, hiding places, and oviposition sites, and are rarely seen or heard away from them. They also feed on insects attracted to electric lights. Their use of a hummingbird feeder is another instance of these geckos exploiting a human provided resource, and one possibly involving social facilitation.

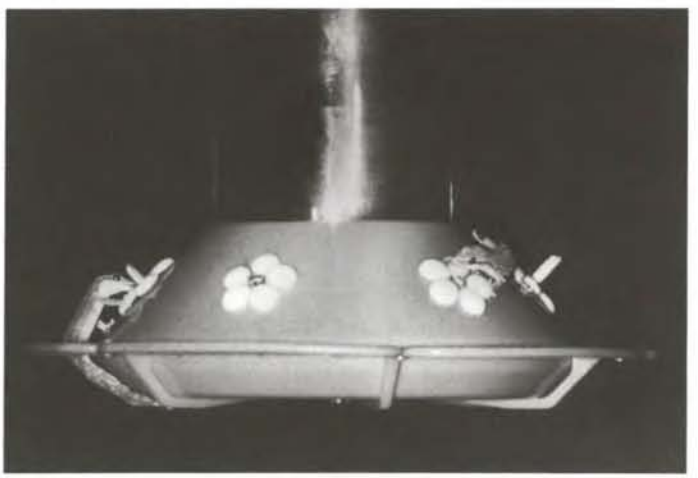

FIG. 1. Two geckos (*Hemidactylus frenatus*) feeding at the hummingbird feeder.

SERPENTES

BOTHROPS NEUWIEDI (Yoperojobobo, Neuwied's Lancehead). **BROOD SIZE**. In Bolivia, in September 1990, two individuals of *Bothrops neuwiedi* were captured live: a female (total length [TL] = 1008 mm, weight = 1000 g) from Dpto. Beni, Estación Biológica Beni (14°38'S, 66°18'W; 190 m elev.) and a male (TL = 830 mm, weight = 823.4 g) from Dpto. Santa Cruz, Cañada Larga (17°32'S, 62°27'W; ca. 400 m elev.). The snakes have been maintained together in captivity, under favorable conditions of temperature (20–26°C) and humidity (ca. 60%) in the city of La Paz (3600 m elev.). They have been fed weekly with white mice (*Mus musculus*) that weighed ca. 20 g each.

Mating behavior was observed during the first week of April 1991 and 1992, and did not differ significantly from behavior previously reported for other terrestrial viperids. In both years gestation was approximately nine months.

In January 1992 a brood of three young was produced. The brood produced in January 1993 numbered 32 young, considerably larger than the previous record of 21 young (Murphy and Mitchell 1984. Acta Zool. Path. Antverp. 78:199–214). The young of the two broods differed in average weight and total length at birth. Data for the 1992 litter are: mean weight = 8.5 g (range 8.2–9.0 g); mean TL = 220 mm (range 210–230 mm); for the 1993 litter: mean weight = 9.4 g (range 8.0–11.0 g); mean TL = 241 mm (range 223–255 mm). These data are not significantly different from those reported by Murphy and Mitchell (*op. cit.*).

HETERODON NASICUS (Western Hognose Snake). **REPRODUCTION**. Six gravid western hognose snakes encountered while drift fence trapping for turtles (Iverson 1991. Herpetologica 47:371–393) at Gimlet Lake on the Crescent Lake National Wildlife Refuge, Garden Co., Nebraska, USA, were captured in late May or June, fed adult *Ambystoma* to satiation, and held in captivity at 24–30°C until they oviposited. The eggs were then incubated to hatching at 25–30°C. The reproductive data from those snakes (Table 1) are concordant with previous data (Pendlebury 1976. Canadian Field-Nat. 90:416–422; Platt 1969. Univ. Kansas Publ. Mus. Nat. Hist. 18(4):253–420), except that 1) the clutch of three represents a new minimum clutch size for the species, 2) four of the five incubation times (46–50 days) are shorter than previously recorded (52–89 days), and 3) the clutch masses of the two smallest clutches (3 and 4 eggs) represent smaller percentages of post-gravid body mass (21 and 22%) than for the other four clutches (52–74%) or for those previously recorded (42–83%). The difference in timing of oviposition between years is attributable to the record cold spring and summer of 1993, presumably delaying onset of egg-laying, and the record warm spring of 1994. which may have led to earlier reproduction (Iverson, unpublished weather records). The field assistance of Tom Akre, Christopher Griffiths. Heather Higgins, Abby Sirulnik, Cameron Young, and my family is gratefully acknowledged.

SISTRURUS CATENATUS CATENATUS (Eastern Massasauga), **FOOD HABITS**. A *Sistrurus c. catenatus* was found inside a northern bobwhite (*Colinus virginianus*) nest on 11 May 1971 in Rober Allerton Park, Piatt Co., Illinois, USA. The habitat in the vicinity of the bobwhite nest was composed of mixed grasses and forbs, staghorn sumac (*Rhus typhina*), and multiflora rose (*Rosa multiflora*).

The bobwhite nest was discovered while removing a pile of wooden box traps. The snake's rattling drew attention to its location in the nest containing nine eggs. When the snake and nest were located, the disturbed snake disgorged two fully intact bobwhite eggs.

Sistrurus catenatus is generally known to prey primarily on small mammals such as *Microtus* and *Peromyscus* (Keenlyne and Beer 1973. J. Herpetol. 7:382–384; Seigel 1986. Biol . Conserv. 35:333–346). This is to my knowledge the first published case of massasauga consumption of eggs. It is surprising that in the intervening 23 years since this observation, there have been no other records of egg predation by massasaugas. Bird eggs, including those of bobwhite, were found in stomachs of *Elaphe obsoleta* (black rat snake) and *Coluber constrictor* (northern black racer) in Virginia (Uhler et al. 1939. Trans. N. Amer. Wildl. Conf. 4:605–622).

The late W. D. Klimstra, Cooperative Wildlife Research Laboratory, Southern Illinois University, reviewed a 1972 draft of this paper. He along with E. Beltz encouraged its publication.

Submitted by **ROGER D. APPLEGATE**, Illinois Natural History Survey, 607 East Peabody Drive, Champaign, Illinois 61820, USA. Present address: Wildlife Division, Department of Inland Fisheries and Wildlife, 650 State Street, Bangor, Maine 04401-5654, USA.

TABLE 1. Snout-vent length (SVL in cm), gravid body mass (BM in g), clutch size (CS), mean egg length (EL in mm), width (EW in mm), and mass (EM in g), clutch mass as a proportion of spent body bass (SRCM), and mean hatchling SVL (in cm) and BM (in g) from six reproductive female Gimlet Lake hognose snakes. Means presented ± 1 S.D. when available.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 26, Number 1.

CAUDATA

AMBYSTOMA TIGRINUM MAVORTIUM (Barred Tiger Salamander). USA: NEBRASKA: MORRILL CO: SE 1/4 Sec. 25, T22N, R52W. June 1993. Roger Heigel. Verified by Jeffrey Mitton. UCM 57354, dried adult now in alcohol. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

DESMOGNATHUS AENEUS (Seepage Salamander). USA: SOUTH CAROLINA: OCONEE CO: Reedy Branch (Rainy Mountain Quadrangle), 34°48'22"N, 83°17'53"W, elev. 365–425 m. 5 June 1995. D. Jackson, P. G. Livingston, C. C. Spencer, B. L. Stuart. Verified by Richard C. Bruce. Charleston Museum (ChM CA4392–CA4394). Three adult specimens collected under leaf litter on bank of Reedy Branch tributary. First record for South Carolina (Harrison, pers. comm., Harrison 1992, Cat. Am. Amph. Rept. 534.1–534.4); Camp Branch (Rainy Mountain Quadrangle), 34°45'[48"N, 83°18'43"W, elev. 365–425 m. 21 July 1995. E. Danell, P. G. Livingston, C. C. Spencer, B. L. Stuart. Verified by Richard C. Bruce. Charleston Museum (ChM CA4395–CA4396). Two adult specimens collected under moss and leaf litter on bank of seep flowing into Camp Branch. Second record for South Carolina.

Submitted by **P. GAYLE LIVINGSTON**, **CHRISTINE C. SPENCER**, and **BRYAN L. STUART**, Highlands Biological Station, P. O. Box 580, Highlands, North Carolina 28741, USA.

SIREN INTERMEDIA (Lesser Siren). USA: TEXAS: KAUFMAN CO: 6.4 km NW Mabank. Two specimens collected from a small pond along Old Rt. 40, 0.8 km W U. S. Rt. 175. 23 July 1993. R. L. Gutberlet, Jr. and D. S. Figueroa. Verified by J. A. Campbell. University of Texas at Arlington Collection of Vertebrates (UTA-A 40755–56). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **RONALD L. GUTBERLET, JR.** and **DANIEL S. FIGUEROA**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA.

ANURA

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: LOUISIANA: EAST BATON ROUGE PARISH: Baton Rouge, Greenhouse at 17810 Sotile Drive, ca. 2.0 km NE jct. Interstate 10 and Highland Road. 27 July 1995. Mike Leggio and Steven Platt. Verified by Richard R. Montanucci. One adult and three neonates collected. Vertebrate Collection, Department of Biological Sciences, Clemson University (CUSC 1263). Parish record; nearest reported populations are in Jefferson Parish (Dundee and Rossman 1989, Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.). Extends range ca. 100 km northeast. Appears established at this site; 50+ neonates were observed throughout the greenhouse. Original introduction probably in houseplants from Florida.

Submitted by **STEVEN G. PLATT** and **LANCE W. FONTENOT**, Department of Biological Sciences, Clemson University, Clemson, South Carolina 29634-1903, USA.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: TEXAS: FLOYD CO: 2.4 km E Barwise. 6 June 1995. Ann M. Anderson, James T. Anderson, and David A. Haukos. Verified by Stephen L. Williams. Museum of Texas Tech University (MTTU 11489). County record; several adult males were heard and seen calling at 2100 h in a flooded playa wetland. The dominant vegetation type was *Coreopsis tinctoria*. This record extends the range northward (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M Univ. Press, College Station. 434 pp.). This species was also discovered in Crosby County, directly south of Floyd, on 6 June 1995 and one specimen was caught (MTTU 11490). Previously documented in Crosby County below Whiter River Reservoir Dam. The Crosby County individuals were found in a flooded playa wetland, 7.3 km S Crosbyton, also in association with *Coreopsis tinctoria;* both playas had an irrigation pit filled with water most of the year. This record fills the hiatus in current known county distribution of this species—Briscoe County to the north and Crosby and Lubbock counties to the south.

Submitted by **ANN M. ANDERSON**, **JAMES T. ANDERSON**, and **DAVID A. HAUKOS**, Range and Wildlife Department, Mail Stop 2125, Texas Tech University, Lubbock, Texas 79409, USA.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). USA: TEXAS: HUDSPETH CO: 14.81 road km S jct. FR 34 and FM 192 on FM 192. 18 July 1995. C. M. Eckerman and T. J. LaDuc. Verified by C. S. Lieb. UTEP 16138–16140, 16146–16148. New county record; extends range approximately 120 km NW of nearest known locality in Jeff Davis County (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, Texas. 434 pp.). Found in ephemeral ponds on the E and W sides of the road. All specimens collected were calling males.

Submitted by **CURTIS M. ECKERMAN**, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

HYLA ANCEPS (NCN): BRASIL: ESPÍRITO SANTO: ARACRUZ: Barra do Sahy (19°50'S, 40°04'W, sea level). 26–27 January 1995. C. F. B. Haddad, J. P. Pombal, Jr. and J. L. Gasparini. Verified by Ulisses Caramaschi. Museu Nacional do Rio de Janeiro (JNRJ 17318). Published distribution of the species is lowlands of the state of Rio de Janeiro in southeastern Brazil (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.). First documented record for the state of Espírito Santo, extending the distribution northward.

Submitted by **CÉLIO F. B. HADDAD**, **JOÃO L. GASPARINI**, Departamento de Zoologia, Universidade Estadual Paulista, C. P. 199, 13506-900 Rio Claro, São Paulo, Brasil, and **JOSÉ P. POMBAL, JR.**, Departamento de Zoologia, Universidade Estadual de Campinas, C. P. 6109, 13083-970 Campinas, São Paulo, Brasil.

PSEUDACRIS CLARKII (Spotted Chorus Frog). USA: TEXAS: FLOYD CO: 2.4 km E Barwise. 5 May &16 May 1995. Ann M. Anderson, James T. Anderson, and David A. Haukos. Verified by Stephen L. Williams. Museum of Texas Tech University (MTTU 11486–11488). County record; several adult males were heard and seen calling after dark in a flooded playa wetland. Previous records include most counties surrounding Floyd, except those to

the east (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **ANN M. ANDERSON**, **JAMES T. ANDERSON**, and **DAVID A. HAUKOS**, Range and Wildlife Department, Mail Stop 2125, Texas Tech University, Lubbock, Texas 79409, USA.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: TEXAS: Cass Co: near Timber Branch, where it flows beneath Texas Rt. 43. 24 July 1993. D. S. Figueroa and R. L. Gutberlet, Jr. Verified by J. A. Campbell. University of Texas at Arlington Collection of Vertebrates (UTA-A 40890). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **RONALD L. GUTBERLET, JR.** and **DANIEL S. FIGUEROA**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA.

PSEUDACRIS TRISERIATA (Western Chorus Frog). USA: COLORADO: Clear Creek Co: Lawson (NE 1/4 Sec. 25, T3S, R74W). 8 July 1995. L. J. Livo. Verified by Richard L. Holland. (UCM 57368, tadpole). First county record. Huerfano Co: 1.1 km E and 0.1 km S jct. Cucharas River with Walsen Arroyo (SE 1/4 Sec. 30, T27S, R65W). 19 May 1995. L. J. Livo, D. Chiszar, H. M. Smith. Verified by Richard L. Holland. (UCM 57333–57334). First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife. 131 pp.). Las Animas Co: jct. Apishapa River and Trujillo Creek (Sec. 18, T31S, R65W). 24 May 1995. L. J. Livo. Verified by Richard L. Holland. (UCM 57332, four tadpoles). First specimens for county (*op. cit.*). The Huerfano and Las Animas records help fill in the little known distribution of this species in the southeast quarter of the state. The Clear Creek record establishes the presence of a fourth amphibian, *Pseudacris triseriata*, in a county once believed to be devoid of amphibians because of mining activities (Porter and Hakanson 1976, Copeia 1976:327–331). The Clear Creek record was obtained during ongoing amphibian surveys conducted by the Central Region of the Colorado Division of Wildlife.

Submitted by **LAUREN J. LIVO**, 1215 S. Osceola Street, Denver, Colorado 80219, USA; **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

PSEUDACRIS TRISERIATA (Western Chorus Frog). USA: COLORADO: Eagle Co: W side Edwards on flood plain east of trailer village. 10 August 1995. H. M. Smith. Verified by Richard L. Holland. UCM 57376–7. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc. 20 pp.).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA; **MICHAEL LAVERTY**, 34185 Colorado Road, McCoy, Colorado 80463, USA; and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA.

PSEUDACRIS TRISERIATA (Western Chorus Frog). USA: COLORADO: Pitkin Co: unnamed pond east of Hardscrabble Lake, White River National Forest (NW 1/4 Sec. 34, T9S, R87W). 15 July 1995. G. P. Horstman and M. Gilbert. Verified by L. J. Livo. UCM Color Slide 105. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife. 131 pp.). This record was obtained during ongoing amphibian surveys conducted by the Northwest Region of the Colorado Division of Wildlife.

Submitted by **GREGORY P. HORSTMAN**, Colorado Division of Wildlife, 711 Independent Avenue, Grand Junction, Colorado 81505, USA.

RANA CATESBEIANA (Bullfrog). USA: COLORADO: Garfield Co: pond at S edge Parachute. 17 September 1995. John A. Rybak. Verified by Richard L. Holland. UCM 57403 (juv). First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc. 20 pp.). Species is common in ponds adjacent to the Colorado River throughout much of the county, although it is introduced.

Submitted by **JOHN A. RYBAK**, 177 Sagemont Circle, Parachute, Colorado 81635, USA; **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

RANA CATESBEIANA (Bullfrog). USA: COLORADO: Phillips Co: Holyoke Lions Fishing Lake, 0.4 km S Rt. 6, 2 km E jct Rts. 6 and 385 in Holyoke. 14 July 1995. David Chiszar. Verified by Richard L. Holland. UCM 57369. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife. 131 pp.).

Submitted by **DAVID CHISZAR** and **DEMETRI THEODORATUS**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA, and **HOBART M. SMITH,** Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

SPEA MULTIPLICATA (New Mexico Spadefoot). USA: COLORADO: Crowley Co: Trainor Ranch, jct 22.5 Road and U Road. 1 July 1995. D. Chiszar and H. M. Smith. UCM 57339, 57341 (adult, transforming young, and tadpoles, cannibal and noncannibal); Kiowa Co: jct Rt. 385 and B Road. 2 July 1995. D. Chiszar and H. M. Smith. UCM 57340 (mangled DOR). Verified by Richard L. Holland. First county records (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife. 131 pp.) and an extension of the known range northeastward about 120 km.

Submitted by **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: COLORADO: Crowley Co: Rt. 71, 3.2 km N Road W. 30 June 1995. D. Chiszar and H. M. Smith. UCM 57338 (plastron only). Verified by Richard L. Holland. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife. 131 pp.).

Submitted by **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: COLORADO: Prowers Co: Willow Creek, 3.92 km E Lamar. 13 July 1995. B. D. Will. Verified by Richard L. Holland. UCM Photograph 100. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Colorado Herpetol. Soc. 20 pp.).

Submitted by **BRYANT D. WILL**, District Wildlife Manager, P. O. Box 785, Lamar, Colorado 81052, USA; **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: NEBRASKA: Scotts Bluff Co: SW 1/4, SW 1/4 Sec. 25, T23N, R53W. 10 July 1995. H. M. Smith. Verified by Rosanne Humphrey. UCM Color Slides 103–104. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

CHRYSEMYS PICTA BELLII (Western Painted Turtle). USA: NEBRASKA: Box Butte Co: N branch Snake Creek at Co. Rd. crossing, NE 1/4 Sec. 15, T25N, R52W. 10 July 1995. R. L. Holland and H. M. Smith. Verified by Lauren Livo. UCM 57363. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

DEIROCHELYS RETICULARIA MIARIA (Western Chicken Turtle). USA: MISSOURI: Butler Co: 2.4 km SE jct. State Road EE and Co. Road 269, Big Cane Conservation Area, 90 m elev. 1–2 June 1995. K. A. Buhlmann and T. R. Johnson. CM Photographic Acc. 36014.1-36014.4. Verified by Joseph T. Collins. Two presumed juvenile females, both 3–4 years old (PL 101 and 117 mm), and one 5-year-old mature male (PL 117 mm) captured in a semi-closed canopy, bald cypress (*Taxodium distichum*) dominated, blackwater wetland. Specimens were released. This species had not been observed in Missouri since 1962 (M. A. Nickerson, pers. obs.) or collected since 1957 (Anderson 1965, The Reptiles of Missouri. Univ. Missouri Press, Columbia. 330 pp.). The western chicken turtle is listed as endangered by the state of Missouri. Historically, chicken turtles were likely common in the bald cypress/bottomland hardwood floodplain swamp forests that have been cleared, ditched, and converted to agriculture, primarily rice farming. Further survey work is needed in the Missouri bootheel region to identify other suitable surviving patches of natural habitat that may contain isolated populations of these turtles.

Submitted by **KURT A. BUHLMANN**, University of Georgia, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA, and **TOM R. JOHNSON**, Missouri Department of Conservation, Natural History Section, P. O. Box 180, Jefferson City, Missouri 65102-0180, USA.

KINOSTERNON ODORATUM (Common Musk Turtle). USA: TEXAS: Kaufman Co: 6.4 km NW Mabank. Specimen was collected from a small pond along Old Rt. 40, 0.8 km W U. S. Rt. 175. 23 July 1993. D. S. Figueroa and R. L. Gutberlet, Jr. Verified by J. A. Campbell. University of Texas at Arlington Collection of Vertebrates (UTA-R 35118). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **RONALD L. GUTBERLET, JR.** and **DANIEL S. FIGUEROA**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). USA: COLORADO: Rio Blanco Co: NE outskirts of Rangely, sandy area 35 m from White River, beyond a wooded area delimiting a housing area. July 1995. Bradley Rouse. Verified by Richard L. Holland. UCM 57381 (carapace and a few other bones of a specimen found recently dead). First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc. 20 pp.), supported as a naturally-occurring population by reports from local residents of others seen widely distributed in the county.

Submitted by **BRADLEY ROUSE**, 317 East Raven, No. 39, Rangely, Colorado 81648, USA; and **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). USA: NEBRASKA: Scotts Bluff Co: Sec. 36, T23N, R53W. 10 July 1995. J. L. Hall. Verified by Lauren Livo. UCM Color Slides 101-102. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **J. LLEWELLYN HALL**, 320714 County Road G, Minatare, Nebraska 69356, USA; **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

SAURIA

ANOLIS EQUESTRIS (Knight Anole). USA: FLORIDA: Collier Co: Naples, 3480 10th Street North. Sec. 22, T49S, R25E. 25 April 1995. Dick Noonan. Verified by David L. Auth. UF 100, 104. Head only, body eaten by a cat. New county record and first record of this species on west coast of Florida (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part Two. Lizards, Turtles & Crocodilians. Windward Publ., Miami, Florida. 191 pp.).

Submitted by **BRICE NOONAN**, Department of Zoology, University of Florida, Gainesville, Florida 32611, USA.

SERPENTES

BOTHROPS ATROX (Common Lancehead): BRAZIL: SERGIPE: Santa Luzia do Itanhy: Lagoa Mangueira Grande, Mata do Crasto (11°20'S, 37°25'W), 0–100 m elev. 7 July 1994. Cristina Arzabe. Verified by I. Sazima. Museu de História Natural, Universidade Estadual de Campinas (ZUEC 01782, adult female; 01783, young male). The name *B. atrox* is currently applied to populations from the "Equatorial forest of Colombia, Venezuela, Guianas, Brazil, Peru, Ecuador and Bolivia" (Hoge and Romano 1972, Sinopse das Serpentes Peçonhentas do Brasil. Serpentes, Elapidae e Viperidae. Mem. Inst. Butantan 36:109–207). The two specimens from the Atlantic forest in Sergipe match in color and scale counts those from the eastern Hylaea (Campbell and Lamar 1989, The Venomous Reptiles of the Latin America. Cornell Univ. Press, Ithaca, New York. 425 pp.). Previous reports from NE Brazil include two specimens from the Atlantic forest in Paraíba and Sergipe [Vanzolini 1981, Papéis Avulsos Zool. S. Paulo 34(19):189–204] and two specimens from the "Cariri" area [Williams and Vanzolini 1980, Papéis Avulsos Zool. S. Paulo 34(6):99–108].

Submitted by **PAULO ROBERTO MANZANI**, Departamento de Zoologia, CP 6109, Instituto de Biologia, Universidade Estadual de Campinas, 13083-970 Campinas, São Paulo, Brazil, and **CRISTINA ARZABE**, Departamento de Biologia, CP 353, Universidade Federal de Sergipe, 49100-000 S. Cristovão, SE, Brazil.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). USA: NEBRASKA: Box Butte Co: SW 1/4, SW 1/4 Sec. 29, T25N, R51W. 9 July 1995. R. L. Holland and H. M. Smith. Verified by Lauren Livo. UCM 57366 (DOR, head and tail only). First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). USA: NEW MEXICO: Socorro Co: Cibola National Forest, San Mateo Mountains, vicinity of Vicks Peak, ca. 62 km S and 16 km W of Magdalena. In south-facing talus slope, ca. 2438 m elev. 28 April 1993. R. E. Anderson. Verified by C. W. Painter. KU Color Slide 11217. Extends range ca. 134 km NNW nearest locality (4.5 km N Hill, Dona Aña County, W. G. Degenhardt, pers. comm.).

Submitted by **RICHARD E. ANDERSON**, Department of Biological Sciences, Southeastern Louisiana University, Box 814, Hammond, Louisiana 70402, USA.

LAMPROPELTIS GETULA CALIFORNIAE (California Kingsnake). MÉXICO: BAJA CALIFORNIA SUR: Vizcaíno Peninsula, ca. km marker 120, ca. midway between San Hipolito and La Bocana. 19 May 1995. Richard A. Erickson and Robert A. Hamilton. Verified by Robert L. Bezy. LACM Photo Collection 1317. Grismer et al. (1994, Bull. So. California Acad. Sci. 93:45–80) recently reviewed the herpetofauna of the Vizcaíno Peninsula. Citing records elsewhere in the Vizcaíno Desert and unconfirmed reports of ranchers in the Sierra Santa Clara, they predicted this snake is widespread on the peninsula. However, this is the first documented record for this little-studied area.

Submitted by **RICHARD A. ERICKSON**, LSA Associates, One Park Plaza, Suite 500, Irvine, California 92714, USA, and **ROBERT A. HAMILTON**, P. O. Box 961, Trabuco Canyon, California 92678, USA.

LAMPROPELTIS TRIANGULUM MULTISTRIATA x TAYLORI (Pale x Utah Milk Snake intergrade). USA: COLORADO: Rio Blanco Co: eastern Rangely. Late May 1995. Tom and Marion Bell. UCM 57378. First county record (Livo 1995, Colorado Amphibian and Reptile Records by County. Publ. Colorado Herpetol. Soc. 20 pp.); Moffat Co: Irish Canyon. October 1946. Mr. Mainland. UCM 7646. Both verified by Richard L. Holland. Supports intergrade status of northwestern Colorado populations (Roth and Smith 1990, Bull. Chicago Herp. Soc. 25:6–7), originally based on one specimen.

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA; **CAROLYN RISTAU**, Department of Psychology, Barnard College, Columbia University, 3009 Broadway, New York, New York 10027-6598, USA; **TOM** and **MARION BELL**, P. MASTICOPHIS BILINEATUS BILINEATUS (Sonoran Whipsnake). USA: ARIZONA: Pima Co: in a rocky, vegetated wash in the foothills of the Coyote Mountains, 24 km NE Kitt Peak, S Arizona Rt. 86 (SW 1/4 Sec. 22, T16S, R8E). 25 April 1992. R. E. Anderson and C. K. Anderson. Verified by J. N. Stuart. Louisiana State University Museum of Zoology (LSUMZ 56929). Extends range ca. 80 km W of known range, and narrows hiatus between it and the disjunct Ajo Mountain whipsnake, *Masticophis bilineatus lineolatus* (Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.).

Submitted by **RICHARD E. ANDERSON**, Department of Biological Sciences, Box 814, Southeastern Louisiana University, Hammond, Louisiana 70402, USA, and **CHRISTOPHER K. ANDERSON**, 5 Raven Road, Canton Massachusetts 02021, USA.

NERODIA ERYTHROGASTER FLAVIGASTER (Yellowbelly Water Snake). USA: ILLINOIS: St. Clair Co: Scott Air Force Base. 1 June 1995. John G. Palis. Verified by Ronald A. Brandon. Southern Illinois University at Carbondale (SIUC R–2865 juv) found beneath roofing-shingle pile adjacent to shallow roadside ditch (NE 1/4 NW 1/4 Sec. 13, T1N, R7W); another juvenile (SIUC R–2866) captured while foraging on *Bufo americanus* and *Hyla chrysoscelis* tadpoles in a small, shallow pool in a mowed field (NE 1/4 NE 1/4 Sec. 14, T1N, R7W). New county record (Smith 1961, Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **JOHN G. PALIS**, Rural Route 1, Box 258, Tell City, Indiana 47586, USA, and **KENNETH S. MIERZWA**, TAMS Consultants, Inc., 180 North Stetson, Suite 3200, Chicago, Illinois 60601, USA.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). USA: FLORIDA: Monroe Co: Key Vaca, Marathon, under debris in small woodland near Mile Marker 50 on U.S. Rt. 1. 23 July 1994. Gregory J. Watkins-Colwell. Verified by J. T. Collins. KU 222389. Not a county record, but is first record for Key Vaca; known to occur throughout southern Florida and has been found on Big Pine Key (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida, Part One: The Snakes. Windward Publ., Miami, Florida. 191 ppp.; Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin, Boston, Massachusetts. 450 pp.).

Submitted by **GREGORY J. WATKINS-COLWELL**, College of Chiropractic, University of Bridgeport, Bridgeport, Connecticut 06601, USA, and **KELLIE A. WATKINS-COLWELL**, William Pitt Family Medicine Center, 128 Strawberry Hill Avenue, P.O. Box 1222, Stamford, Connecticut 06904, USA.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). MASSACHUSETTS: Suffolk Co: Boston, a building on Fulton Street, North End. 10 November 1993. Verified by V. Wallach. MCZ R-178146. Total dorsal scale count is 320-322. This species was first discovered in Massachusetts in the same building on 25 November 1990, as reported by Wallach et al. (1991, Herpetol. Rev. 22:68). Both were found in glue (i.e., sticky) traps in the basement. While investigating the latest occurrence, it was learned that there were an additional three snakes in 1990, but that they had been thrown away by the building's owner. One of those was found crawling across the floor.

After the 1993 occurrence, the basement and alley behind the building were searched in an effort to locate more snakes and determine how they could enter or survive in the house. There are drain pipes and cracks in the cement floor and piles of debris in the boiler/washer room. From the back alley, the wooden beams in the ceiling of the basement were visible through a cracked wall. There were ant hills in cracks along the building's foundation. The owner, who has lived in the building for about 25 years, had only seen blind snakes on these two occasions and related that no exotic plants or other items were taken into the apartment prior to

the second occurrence. In 1990, the same person said that potted plants had been taken into one of the building's upstairs apartments. Rat poison and glue traps had been placed throughout the basement and first floor and the lower floors fumigated once a year.

Braminy blind snakes were collected in the same building three years apart, which confirms that this parthenogenic, tropical reptile is established in Boston. The potential hazards (e.g., poison) in the building, variety of potential entry points, and time of year when the snakes appeared, suggest they are living in the soil near the building and may be seeking warmth and cover in the building as the outside temperature declines.

Other than Boston, the two northernmost records for this snake in the contiguous United States are Lake Placid, Highlands County, Florida (Meshaka 1994, Herpetol. Rev. 25:34), about 1400 mi SSW Boston, and New Orleans, Orleans Parish, Louisiana (Thomas 1994, Herpetol. Rev. 25:34), about 1600 mi SW Boston.

Submitted by **GWILYM S. JONES**, **LESLIE A. THOMAS**, and **KEVIN WONG**, Center for Vertebrate Studies, Department of Biology, Northeastern University, Boston, Massachusetts 02115, USA.

VIRGINIA VALERIAE (Smooth Earth Snake). USA: FLORIDA: Okaloosa Co: Eglin Air Force Base, Range Road 211 at Milligan Creek Bridge (Sec. 32, T2N, R25W). 26 June 1995. J. B. Jensen. Verified by Paul Moler. UF 99675. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part One, The Snakes. Windward Publ., Miami, Florida), bridging a hiatus in the western portion of the Florida panhandle (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin, Boston, Massachusetts. 450 pp.). Individual was captured along the ecotone between longleaf pine-turkey oak sandhill and a clear titi-bordered seepage stream.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA, and **MARK A. BAILEY**, Alabama Natural Heritage Program, 64 North Union Street, Montgomery, Alabama 36130, USA.

New Texas Herpetofaunal County Records Represented In The Tulane University Museum Of Natural History

With the combining of the long-standing Tulane University Amphibian and Reptile Collection (TU) with a separate collection accumulated by Royal D. Suttkus at the Tulane Museum of Natural History, which now retains the TU acronym, and the cataloging of a large backlog of uncataloged specimens, I decided to review our distributional records in relation to those published. These records are supplementary to those in Dixon (1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. xii + 434 pp.) and subsequent records found in *Herpetological Review*, the *Texas Journal of Science*, and miscellaneous sources listed in the *Zoological Record*.

Except for *Rana grylio*, verifications of amphibian records were supplied by David A. Good and those of reptiles were made by Douglas A. Rossman, both of the Louisiana State University Museum of Natural Sciences.

Ambystoma maculatum larvae (Spotted Salamander). Tyler Co: tributary to Little Beech Creek, 2.3 km S of north gate on north Big Thicket park boundary. 20 March 1978. R. D. Suttkus and G. H. Clemmer. TU 22963–23024. This record fills in a gap within the range suggested by Dixon (*op. cit.*).

Necturus beyeri (Gulf Coast Waterdog). Hardin Co: Turkey Creek, 5.6 km E of U.S. Rt. 69 & U.S. Rt. 287. 7 October 1978. R. D. Suttkus and H. L. Bart, Jr. TU 21264; Hickory Creek, 2.4 km E U.S. Rt. 69 and U.S. Rt. 287. 7 October 1978. R. D. Suttkus, H. L. Bart, Jr. TU 21265–21268; Hardin-Tyler Co. line road, Beech Creek, 8.1 km W Farm to Market Road. 92. 4 August 1982. R. D. Suttkus and M. Blackwell. TU 21269; Village Creek at Farm to Market Road. 418, 5.3 km E Kountze. 12 May 1982. R. D. Suttkus and Trace. TU 21200; Village Creek below Silsbee bridge on U.S. Rt. 96. 6 June 1959. R. D. Suttkus and R. C. Cashner. TU 21375–21376.; Mill Creek, tributary to Village Creek, 3.9 km W Silsbee, Texas Rt. 327. 20 February 1978. R. D. Suttkus, G. H. Clemmer. TU 28993.

Pseudacris clarkii (Spotted Chorus Frog). Randall Co: Palo Duro Canyon State Park. 26 July 1967. F. Jannett. TU 30597–30598. This record fills in a small gap in the northwestern perimeter of the range.

Rana grylio (Pig Frog). Jasper Co: Neches River along left bank, 1.6 km W Evadale by U.S. Rt. 96. 12 May 1982. R. D. Suttkus and V. Trau. TU 23345 (119 larvae). This is a tentative determination made from tadpoles less than 25 mm in length. Ronald Altig examined some of this lot of specimens and thinks they are *grylio*. He did ask if they had a bright metallic band across the back when alive (a feature not mentioned in his key; 1970, Herpetologica 26:180–207) The long period in preservation may have caused fading of the metallic band, and, as Altig stated, determination of young stages always is difficult. Altig indicated that the tadpoles are not of the *Rana pipiens* complex and that *Rana catesbeiana* would be the only conflict in identification for that area. I did have many *catesbeiana* tadpoles of various sizes from southeastern Texas for comparison.

Rana sphenocephala (= *Rana utricularia*). (Southern Leopard Frog). Clay Co: Red River along right bank at Texas Rt. 79, 10.6 km NE Byers. 13 May 1987. R. D. Suttkus and W. Palmer, Heitzman, and McInnis. TU 22039. This extends range ca. 21 km NW of Dixon's suggested range limit.

Apalone mutica mutica (Midland Smooth Softshell). Jasper Co: Neches River along left bank, 15.2 km below old U.S. Rt. 96 bridge. 20 March 1982. R. D. Suttkus, E. B. Peebles, D. L. Rome. TU 21659, 21627–21629; Neches River along left bank, 9.5 km below old U.S. Rt. 96 bridge. 20 March 1982. R. D. Suttkus, E. B. Peebles, D. L. Rome. TU 21660–21662. Orange Co: Neches River along left bank, 0.8 km upstream from mouth of Pine Island Bayou. 12 July 1979. R. D. Suttkus, A. Black, S. Osborn, and S. Utter. TU 28148. Tyler Co: Neches River along right bank, 8.1 km S Spurger off Farm to Market Road. 1013. 7 October 1978. R. D. Suttkus and H. L. Bart, Jr. TU 30690; Neches River along right bank, 0.5 km N of Farm to Market Road. 1013. 4 June 1977. E. C. Beckham and R. D. Suttkus. TU 31123; Neches River along right bank, 8.7 km E Spurger, Farm to Market Road. 1013. 18 September. 1982. R. D. Suttkus, D. Behler, P. Burris. TU 21664.

Apalone spinifera pallida (Pallid Spiny Softshell). Cottle Co: Buck Creek at Texas Rt. 1168. 18 May 1989. R. D. Suttkus and C. Jones. TU 21668.

Apalone spinifera emoryi (Texas Spiny Softshell). Crockett Co: 45.2 km S Sheffield in Pecos River. 14 July 1963. Tulane Environmental Biology Class. TU 30071.

Graptemys kohnii (Mississippi Map Turtle). Jefferson Co: Pine Island Bayou along right bank, 1.2 km below first pipeline below Farm to Market Road. 105. 17 September 1982. R. D. Suttkus and D. Taylor. TU 21652; Newton Co: Sabine River along right bank at Taylor Bend, 6.6. km SSW Bancroft, Louisiana. 26 July 1982. R. D. Suttkus, W. M. Brenneman. TU 21653; Jefferson-Hardin county line: Pine Island Bayou 4.4 km S Sour Lake, Texas Rt. 326. 5 September 1982. R. D. Suttkus and M. Blackwell. TU 21477, 21654. Newton Co: Sabine River along right bank 1.6 km below Armstrong Lake. 18 October 1979. R. D. Suttkus; Sabine Co: 12.9 km SW Toro, Louisiana in Sabine River. 1 July 1963 . R. D. Suttkus, M. G. Ferraro TU 29889; Sabine River along right bank, 1.2 km below first pipeline below Farm to Market Road 105. 26 July 1982. R. D. Suttkus and W. M. Brenneman. TU 21653. Tyler Co: Neches River, 8.1 km E Spurger, 1.1 km off Farm to Market Road. 1013. 27 September 1977. R. D. Suttkus, E. C. Beckham, S, Rohmann. TU 30553.

Macroclemys temminckii (Alligator Snapping Turtle). Tyler Co: 24.2 km E Woodville in Beech Creek, 4.4. km S of north Big Thicket park boundary. 20 March 1978. R. D. Suttkus. TU 21300.

Sternotherus carinatus (Razorback Musk Turtle). Jefferson Co: Willow Creek, tributary of Pine Island Bayou, 4.5 km S of Sour Lake via Texas Rt. 326. 5 September 1982. R. D. Suttkus and M. Blackwell. TU 21428; dead end oxbow along right bank of Pine Island Bayou. 25 March 1979. R. D. Suttkus, C. Miller, J. Faletto. TU 27098; Polk Co: Big Sandy Creek at Farm to Market Road. 1276, 7.1 km SE Jct. U.S. Rt. 190. 20 March 1978. R. D. Suttkus and G. H. Clemmer. TU 21419; E Fork Double Branch, 11.1 km NW Dillardsville. 2 June 1982. R. D. Suttkus. TU 21423; Menard Creek, 1.1 km W Segno on Farm to Market Road. 943. 15 July 1978. R. D. Suttkus and G. H. Clemmer. TU 31112. Tyler Co: Theuvenins Creek, 13.1 km W Spurger via Farm to Market Road. 1013. 14 July 1978. R. D. Suttkus, E. C. Beckham, S. Rohmann. TU 31103; Neches River, 9.0 km E Spurger, just north of Farm to Market Road. 1013. 28 July 1977. R. D. Suttkus, G. H. Clemmer. TU 31141, 31273; Neches River along right bank opposite Big Creek. 28 December 1978. R. D. Suttkus. TU 28149; B. A. Steinhagen Reservoir, Neches River along right bank just above Town Bluff Dam. 3 February 1979. R. D. Suttkus, J. Falleto, , C. Miller; Neches River along right bank just above Town Bluff Dam at Town Bluff. 17 February 1979. R. D. Suttkus, C. Miller. Sabine Co: Palo Gaucho Bayou, 15.2 km NE Hemphill. 13 July 1964. R. D. Suttkus and Environmental Biology Class. TU 30727.

Trachemys scripta elegans (Red-eared Slider). Tyler Co: Drakes Branch at a dirt road, 12.4 km WNW Fred. 28 September 1977. R. D. Suttkus, E. C. Beckham. TU 21580.

Eumeces fasciatus (Five-lined Skink). Kerr Co: Kerrville. August 1948. A. H. Chaney. TU 5822–5823. I view this as a probable erroneous locality. It is perhaps 190 km NW of the closest record and in a well-collected area. Chaney, who collected many amphibians and reptiles in the Kerrville area and lists specific dates in August 1948, says (in litt.) that he cannot identify these specimens in his notes and that he traveled around quite a bit during that time. The Kerrville area has some extensive forested areas that might seem to be suitable habitat for the species, but such a habitat seems to be principally occupied by *Eumeces tetragrammus brevilineatus*. *Eumeces tetragrammus* and *E. fasciatus* do overlap some in part of east central Texas but a hiatus exists between the species farther to the south. Collectors should check carefully for *E. fasciatus* in east central Texas.

Tantilla nigriceps (Plains Blackhead Snake). Dallam Co: 21.5 km NE Dalhart. 21 July 1967. H. A. Dundee. TU 18591–18593. This is not a new county record, Chiszar and Smith (1992, Herpetol. Rev. 23:124) having reported it from 13.75 km NW Dalhart, but it does extend the NW limits of the known range in Texas.

Additional Geographical Records for Reptiles in Virginia

The herpetological collection of the Department of Biology, George Mason University, Fairfax, Virginia (GMU) includes a number of specimens representing locality records for Virginia reptiles not included in the recent publication by Mitchell (1994) nor its predecessor by Tobey (1985). These records are presented here. In addition, Mitchell (1994) referred to several locality records taken from Ernst (1992), Ernst (pers. comm.; now Ernst et al., in press) or Ernst and Barbour (1989) as "Unvouchered Records" and plotted them on his distribution maps as hollow circles. Data confirming these specimens are also presented below.

Chrysemys picta (Painted Turtle). PREVIOUSLY UNVOUCHERED RECORDS: Independent City of Alexandria, marsh on south side of George Washington Memorial Parkway, 1 mi S National Airport. June 1982. J. E. Lovich. GMU 1237. Fairfax Co: Mason Neck National Wildlife Refuge, Kane's Creek bald eagle nest site. 22 March 1984. S. Haines. GMU 2646–2647. Burke Lake Park, nr dam. 27 March 1985. S. W. Gotte, S. Elfers. GMU 2654; August 1980. C. W. Brown. GMU 1214. Fort Belvoir, Accotink Creek. 21 March 1987. S. W. Gotte, A. F. Laemmerzahl. GMU 3167; 15 March 1987. S. W. Gotte, J. F. McBreen. GMU 3178–3180; 500 yds from parking lot nr Accotink Creek. 10 April 1987. S. W. Gotte, J. F. McBreen. GMU 3193–3195; bald eagle's nest site. May 1990. S. W. Sekscienski. GMU 3876; Accotink Bay Wildlife Refuge. 20 April 1994. C. H. Ernst. GMU 4002. Reston, Nike Park. 3 June 1992. P. J. King. GMU 3930–3931.

Clemmys guttata (Spotted Turtle). PREVIOUSLY UNVOUCHERED RECORDS: Fairfax Co: Great Falls, 100 m from Potomac River nr Interpromontory Road. 27 July 1984. S. W. Gotte. GMU 2409. Fort Belvoir, Pohick Bay. 1990. S. W. Gotte. GMU 3919; 4 April 1986. S. W. Gotte. GMU 2905–2906; 28 May 1987. S. W. Gotte, A. F. Laemmerzahl, J. F. McBreen. GMU 3395. Stafford Co: no precise locality or collection data. GMU 3753.

Clemmys insculpta (Wood Turtle). PREVIOUSLY UNVOUCHERED RECORDS: Warren Co: 1.6 mi W of Shenandoah River Bridge, U. S. I-66. 26 October 1990. L. Wanrow. GMU 3916.

Pseudemys rubriventris (Redbelly Turtle). PREVIOUSLY UNVOUCHERED RECORDS: Fairfax Co: Burke Lake Park. 7 October 1988. R. Richardson. GMU 3676. Mason Neck National Wildlife Refuge. 16 March 1987. A. F. Laemmerzahl. GMU 3428.

Terrapene carolina (Eastern Box Turtle). NEW COUNTY RECORD: Culpeper Co: Phelps Wildlife Management Area: 13 August 1987. S. W. Gotte, A. F. Laemmerzahl. GMU 3433–3435. Fills gap between Prince William, Stafford and Fauquier counties. PREVIOUSLY UNVOUCHERED RECORDS: Fairfax Co: Reston, South Fork Little

Difficult Run at Foxmill Road. 17 February 1982. S. W. Gotte, J. E. Lovich, P. Fuller. GMU 974; jct. Reston Ave. and Foxmill Road. 9 November 1984. R. Furey. GMU 2839. Lorton, Gunston Road, 4.7 mi from U. S. Rt 1. 26 May 1988. S. W. Gotte. GMU 1570; Gunston Cove. 4 April 1986. S. W. Gotte. GMU 2909, 2950–2952; April 1987. S. W. Gotte. GMU 3438. Centreville, jct. Union Mill and Braddock Roads. 22 May 1984. C. H. Ernst. GMU 2038; jct. Braddock and Clifton Roads. 16 August 1987. A. F. Laemmerzahl. GMU 3430. Great Falls, Interpromontory Road. 2 August 1984. S. W. Gotte. GMU 2408; City of Great Falls. August 1988. GMU 3640. Fairfax: Fairfax Circle. December 1983. M. G. Emsley. GMU 1717; George Mason University Campus. 12 April 1976. C. H. Ernst. GMU 4. June 1972. C. H. Ernst. GMU 318–322. May 1986. C. H. Ernst. GMU 2955. Mason Neck National Wildlife Refuge: May 1984. D. P. Kelso. GMU 1799–1801; 27 October 1984. C. H. Ernst. GMU 2584–85; 29 June 1985. C. H. Ernst. GMU 2702–2703; 16 June 1985. S. W. Gotte. GMU 2710–2711; 25 July 1985. C. H. Ernst. GMU 2713; 2 March 1986. C. H. Ernst, E. M. Ernst. GMU 2894–2895; 14 April 1986. C. H. Ernst. GMU 2940–2949; 7 June 1986. E. M. Ernst. GMU 2954; 30 July 1986. A. F. Laemmerzahl. GMU 1739, 3297; 7 May 1987. C. H. Ernst. GMU 3369; May 1986. S. W. Ernst. GMU 3677, 3766; May 1993. T. P. Boucher. GMU 3982. Burke Lake Park: May 1975. C. H. Ernst. GMU 817–818; 14 April 1976. C. H. Ernst. GMU 860; April 1982. L. A. Ernst. GMU 1429; April 1983. J. E. Lovich. GMU 1529; March 1984. J. Snyder. GMU 1796; March 1986. S. W. Gotte. GMU 2888–2889; 28 April 1986. C. H. Ernst. GMU 2939; 27 March 1991. C. H. Ernst. GMU 3850. Fort Belvoir: 24 April 1989. S. C. Belfit. GMU 3697–3698; 27 March 1991. C. H. Ernst. GMU 3853; 21 February 1990. S. Belfit. GMU 3857. Arlington Co: Gulf Branch Nature Center. Winter 1987. J. F. McBreen. GMU 3505. Lee Co: Station Creek at U. S. Rt. 58. 30 April 1978. T. C. Barr, Jr. GMU 2298. Prince William Co: Lake Brittle. 28 March 1985. S. W. Gotte, K. Ballard. GMU 2687; Conway-Robinson State Forest, U. S. Rts. 29 and 211. March 1986. D. Nusbaumer. GMU 2887; Manassas. 15 May 1986. C. H. Ernst. GMU 3000. Frederick Co: Mountain Falls, 1 mi past Rt. 606–608. 1986. D. Nusbaumer. GMU 2883–2886.

Trachemys scripta (Slider). PREVIOUSLY UNVOUCHERED RECORDS: Independent City of Alexandria, Belle Haven Park. 23 March 1992. C. H. Ernst. GMU 3922 (*Trachemys s. scripta*). Fairfax Co: Mason Neck National Wildlife Refuge. 30 August 1984. S. W. Gotte. GMU 2625–2630 (five juvenile *Trachemys s. elegans* hatched from eggs laid 19 June 1984); August 1984. S. W. Gotte. GMU 2880–2881, 2913 (three juvenile *Trachemys s. elegans* hatched from eggs laid June 1984). The slider has been introduced into northern Virginia via the pet trade and exists as a reproducing population residing mostly in the tidal marshes of the Potomac River. The subspecies *T. s. scripta* and *T. s. elegans* are both present, with *elegans* dominant; some intergradation has occurred.

Kinosternon subrubrum (Eastern Mud Turtle). PREVIOUSLY UNVOUCHERED RECORDS: Fairfax Co: Pohick Bay. 12 June 1987. J. F. McBreen, S. W. Gotte and A. F. Laemmerzahl. GMU 3411; Gunston Cove at Pohick Creek. May 1987. J. F. McBreen. GMU 3436; Fort Belvoir, bald eagle nest site. May 1990. S. W. Sekscienski. GMU 3875. Mason Neck National Wildlife Refuge. May 1994. S. Zylstra. GMU 4008.

Sternotherus odoratus (Common Musk Turtle). PREVIOUSLY UNVOUCHERED RECORDS: Fairfax Co: Fort Belvoir, bald eagle nest site. May 1990. S. W. Sekscienski. GMU 3866–3874. Rt. 7, 5 miles E of Laurel Hill Road. 16 June 1987. A. F. Laemmerzahl. GMU 3393. Burke Lake Park. 1 November 1990. C. H. Ernst. GMU 3814.

Lampropeltis calligaster (Prairie Kingsnake). NEW COUNTY RECORD: Albemarle Co: U. S. Rt. 29. 0.2 miles N of Rivanna River. 29 April 1985. S. W. Gotte. GMU 2691. Fills gap between Madison and Culpeper counties and Louisa County.

Lampropeltis getula (Common Kingsnake). NEW LOCALITY RECORD: Prince William Co: Manassas. 14 May 1983. C. H. Ernst. GMU 1647. Female, one of copulatory pair; male still alive at GMU. Extends range in northern Virginia one county southwest from Fairfax County.

Lampropeltis triangulum (Milk Snake). NEW LOCALITY RECORD: Clarke Co: Blandy Experimental Farm & State Arboretum. May 1983. S. W. Gotte. GMU 4003. Long term captive. Died July 1994. Completes county sequence in northwestern Virginia.

Opheodrys aestivus (Rough Green Snake). NEW COUNTY RECORDS: Clarke Co: Rt. 601. 2 miles N of Rt. 7. 22 September 1984. S. W. Gotte, K. Ballard, B. Milsap. GMU 2525. Extends range one county west in northwestern Virginia. New Kent Co: Rt. 618, 2 mi NW U.S. Rt. 60. 12 October 1984. C. H. Ernst, S. W. Gotte, J. Snyder. GMU 2526. PREVIOUSLY UNVOUCHERED RECORD: Westmoreland Co: 0.5 mi on Rt. 204 beyond Rt. 3. 18 April 1987. J. F. McBreen. GMU 3356.

Agkistrodon contortrix (Copperhead). PREVIOUSLY UNVOUCHERED RECORDS: Fairfax Co: Great Falls, Jefferson Run Road. 2 June 1983. S. W. Gotte. GMU 1547. Clifton, Kinchloe Fields. May 1986. J. Chick, J. Slapcinsky. GMU 2996. Hemlock Overlook Regional Park. 30 April 1991. J. C. Wilgenbusch. GMU 3848.

Crotalus horridus (Timber Rattlesnake). PREVIOUSLY UNVOUCHERED RECORDS: Rappahannock Co: Rt. 610, 0.5 mi W of Chester Gap, 2200 ft. elev: 20 May 1985. S. W. Gotte. GMU 2692; 3 June 1985. S. W. Gotte. GMU 2698; 2300 ft. elev. 24 June 1985. S. W. Gotte. GMU 2700. Augusta Co: 1.3 mi W of Camp Todd, 3700 ft. elev. 5 June 1985. D. W. Johnson. GMU 3304.

Caiman crocodilus (Spectacled Caiman). NEW COUNTY RECORD: Fairfax Co: Lake Fairfax Park, in shallows of lake. October 1972. C. H. Ernst. GMU 709. Mitchell (1994) only presents data on three individuals caught in Virginia (Independent City of Norfolk, Henrico County, and Arlington County). The Fairfax County specimen (91 cm SVL) was caught alive. It had apparently been a resident of the lake most of the summer, having been observed by park personnel several times during that period. Fresh fecal contents showed it had been eating fish.

BOOK REVIEWS

A Naturalist in Florida: A Celebration of Eden, by Archie Carr. (Edited by Marjorie Harris Carr. Foreword by Edward O. Wilson.) Yale University Press: i-xviii + 264 pp. Hardcover. US $28.50. ISBN 0-300-05589-7.

Here is the book that Archie Fairly Carr, Jr., always wanted to write about his beloved Florida, but never got around to doing. Yet every word is his, with phrases and clauses strung together in his own inimitable style.

The seeming paradox was cleverly bridged by his devoted wife, Majorie Harris Carr, now his widow. She assembled, skillfully blended, and synthesized what I, an old-timer, have enjoyed to the full—a new book by Archie Carr. The text was abstracted or adapted from a variety of sources. A few of the chapters are from his books and papers, a sprinkling are from hitherto unpublished manuscripts, but most are from magazine articles that appeared years ago and which, until now, were unknown to non-subscribers. The result is a highly readable collection of Archie's observations on various aspects of the natural history of Florida, and the vast changes it has endured as much of its wildlife and habitats have been destroyed by the hordes of people who have invaded what was truly a naturalist's Eden in pioneer days.

There is a wealth of information for the herpetologist in this book. The titles of many chapters are indicative, such as "Tails of Lizards," "Living with an Alligator," "In Praise of Snakes," and a virtual treasury of observations and comments on Florida's largest and most widespread reptile in a lengthy essay on "Alligator Country." Other chapters are devoted to herps even though their titles fail to suggest it. Further, in most of those on other subjects, amphibians and reptiles occupy prominent and unexpected roles in Archie Carr's narratives. In a chapter on "The [Spanish] Moss Forest," for example, there is a cogent discussion about the eastern spadefoot, *Scaphiopus holbrookii*, and how its behavior resembles that of its relatives in the arid Southwest. Also, under "Water Hyacinths" he explains how bonanzas of amphibians and reptiles can be found by rolling masses of the pestiferous floating plants ashore and sorting through them.

Archie Carr was first and foremost a herpetologist, but he was also deeply interested in all aspects of the Floridian fauna and flora. He loved Florida, where he spent most of his life, despite his many excursions and sometimes longer stays in the Tropics. He was a skilled writer who had the gift of making some of his prose read almost like poetry. Several of his books won him prizes

and medals, and he was hailed as one of the best nature writers of the century. His brilliant mind and keen powers of observation could make even the most prosaic natural history event come alive and seem important. Florida was Archie's favorite topic, with the possible exception of turtles. He was one of the world's foremost authorities on those reptiles, especially the sea turtles. He was a highly respected scientist, and unquestionably was one of the all-time greats among the faculty members of the University of Florida at Gainesville. Unhappily, we lost him in 1987.

Archie Carr was no armchair naturalist. He relished being in the field, pursuing his studies and observations, and also meeting the common man and gathering information from hunters, fishermen, farmers, and others who spent much of their time out-of-doors. His text is flavored with the "ain'ts," "don't need nones," and "let's ketch its" of his poorly educated acquaintances. An amusing and instructive part of this book is his contribution to the patois of the Florida Crackers who had their own names for a great variety of things. A torrential downpour was a "frog-choker rain." A water lily was a "bonnet." Certain kinds of fishes were "stumpknockers," "pusselguts," and "hogchokers." A "cut-bait fisherman" was one who used dynamite instead of hook and line. Kinosternid turtles were invariably called "stinkjims" and the Suwanee cooter, *Pseudemys concinna suwanniensis*, that Archie himself described as a new taxon, was the highly esteemed protein component of "Suwannee chicken stew."

Standardization of names, for the sake of accurate communication, is important, as well I know. I chaired the pioneer committee on herpetological common names of the American Society of Ichthyologists and Herpetologists during the 1950's. But colloquial names also have their place, both in history and as picturesque punctuations of our language. Regrettably, most of them are dying out as we are homogenized from coast to coast, chiefly by television. In a sense, we are becoming almost like clones of one another, with choice bits of regional Americana rapidly slipping away.

In her "Preface" Marjorie Carr mentions that when, in the late 1960's, Archie started to write a book about Florida he "immediately sensed a danger looming." Without care his writings might become a "lament" on what has happened to Eden. So he approached it from the positive side, recounting a great many of his interesting and pleasurable experiences, and he pointed out how some of the animals have made comebacks. Nonetheless, he sneaked in "some factual tooth-gnashing every now and then" about how thoughtless and avaricious humans have contributed to the loss of the beauty, tranquility, and living treasures of our most tropical state. Margie bore this in mind while assembling the various parts of this lively compendium of her late husband's literary contributions.

Maps are included showing place names mentioned in the text, valuable tools for orientation. Archie's writings span a period of fifty years, and the nomenclature used for some of the organisms is out of date. Isn't it always so? Scientific names change as studies progress. Special thanks are due to Marjorie Carr for making this book possible. It is a tribute to her as well as to Archie.

Snake Identification. Identity Software, 1994, Intec Ltda., Neotropics Genera Version 1; Rio de Janeiro, Brazil, or La Mesa, California, USA.; 1.5 megs, Windows 3.1 or later; US $69.00.

I commend the author (unknown) for the effort of obtaining the necessary copyright releases to utilize the taxonomic data presented in the keys to the neotropical snake genera by Peters and Orejas-Miranda (1970) and Peters, Orejas-Miranda, and Vanzolini (1986), in their *Catalogue of the Neotropical Squamata, Part 1: Snakes* (wrongly cited by Intec Ltda., as Peters and Robert Donoso-Barros).

The program is easily installed and I am sure the company recommends that you have at least 4 megs of RAM to run Windows 3.1.

There are two ways to obtain the unknown snake genus for which you may be searching. The first is a Sequenced-Key Menu that allows you to select one choice of a dichotomous couplet. Once you have selected the character, a second couplet appears and again you make a choice, etc. Once you have selected all of the characters that fit your unknown genus, the correct? genus should pop up on your screen.

There is also a Random-Key Menu that allows you to select from a list of 244 characters (duplication removed from the Sequenced-Key list of 366 characters). As you utilize the character set, you are allowed to save each character, use an **update** icon to search the data base, and eliminate genera lacking those characters. You may continue adding characters and searching with the **update** button until you have exhausted your choices or found the answer. Identity Software has indicated that there is a problem if you enter characters from both the Sequenced-Key and the Random-Key. There are "several of the genera that cannot be completely separated. This situation occurs because the initial list of characteristics was developed for use with the sequenced key." The company claims that a future update will eliminate the discrepancy.

You cannot add or delete characters to or from either key. You must use those that are provided. Future updates will include information that may better define the genera.

Printing the information found in Version 1 is not as easy as suggested by the company. When I follow the directions for printing the screen by selecting the **Print** button, I receive blank pages, rather than the print screen data selected (although this may simply be a non-configured print mode in my printer [HP 500+]).

However, in good conscience, I cannot recommend the purchase of *Snake Identification* software at this time. There are several reasons for not using the current version.

1. The data are old and though the keys may work for many of the genera, there are a number of revised and new genera not included, whereas others that have been synonymized, resurrected, or newly described are present. This creates considerable taxonomic confusion. Some of the new genera included are *Bothriechis*, *Bothriopsis*, *Ophryacus*, and *Porthidium*. Those genera not included are *Cerrophidion*, *Crisantophis*, *Emmochliophis*, *Enuliophis*, *Exiliboa*, and *Rhadinophanes*. Resurrected genera not included are *Cercophis*, *Tropidodryas*, and *Echinanthera*. Synonymized genera included are *Dromicus*, *Leimadophis*, *Lygophis*, *Leptomicrurus*, *Paraptychophis*, and *Paroxyrhophus*. The writer of the program states that the initial version (version 1) "does not include all of the most recent data; however the random key will be updated in order to provide up-to-date information about the recognized genera." The writer of the software states in the registration form, "that *snake identification* will be updated to include the most recent information. If you would like to receive at least one upgraded version of this program as soon as available, please

check one of the following..." The "following" represents two boxes, one for a money order, the other for a check, each for $69.00, and payable to Identity Software. There is no indication of how soon the software will include new information, nor who is keeping track of the rapidly changing status of generic names, character adjustments, and geographic distributions. Most of the data included represents our knowledge of 25 years ago. Today, DNA sequencing, other types of protein analyses, osteological and soft anatomy discoveries are making rapid changes in generic concepts. In an attempt to use the present program to identify South and Middle American snake genera through representative species, I was frequently presented with the wrong genus. Some species that appear difficult to identify to genus are within *Mastigodryas*, *Rhadinaea*, *Liophis*, *Tachymenis*, and *Leptodeira*. In some cases, the data set presented in the couplet is in error; e.g., species of *Leptodeira* have a maxillary diastema and grooved, enlarged rear teeth. The data set used to identify *Leptodeira* through the Sequenced-Key does not contain a diastema nor grooved teeth. Instead, character #190 is present, "Teeth-Shape-Maxillary-Diastema absent, bk teeth not enlarged." However, the Random-Key data set contains character # 215, "Teeth-Maxillary-Size-bone not reduced, teeth present before enlarged grooved fangs." Therefore it is possible to identify *Leptodeira* in the Random-Key, but not in the Sequenced-Key.

2. When most of us are using keys to identify a snake, we usually have an alcoholic specimen in the tray, we thumb through the key with one hand and examine characters with the other, and normally sit in front of a microscope rather than a computer. In general, we would not allow a piece of expensive electronic equipment to be covered with snake scales and alcohol. The computer program for snake identification requires us to record all of the necessary data from the specimen **prior** to keyboard use. Without prior knowledge of all of the character states in the program, we are required to take data that we would not normally record for every specimen.

3. Perhaps the greatest problem with Version 1 is the out-of-date nature of the some of the generic characters for various genera. Because the genus is an artificial category, many of the attributes are subject to change as more species are added or deleted from a genus; e.g., a genus with all species having a 17-17-15 scale row reduction with apical scale pits, will change drastically by adding a new species without a reduction and without apical scale pits. An excellent example of an abrupt change is the recent description of the new genus *Xenoxybelis* (Machado 1993) for *Oxybelis argenteus*, based upon hemipenial morphology.

I do not envy the person(s) of Intec Ltda. who have the task of keeping up with the rapid changes taking place in snake systematics today. I believe that the future updates that include species identification keys will be a much better purchase than the one at hand.

Decline of the Sea Turtles: Causes and Prevention. Committee on Sea Turtle Conservation, Board of Environmental Studies and Toxicology, Board on Biology, Commission on Life Sciences, National Research Council. 1990. National Academy Press, Washington, D.C. xv + 259 pp. US $14.95.

A valuable compendium on sea turtles, this book was unabashedly written as a political response to a menacing situation in the USA: millions of dollars of federal funds spent to save turtles, but a conservation—and political—situation which continued to deteriorate. Much of this money was spent on the development of technology to reduce the incidental capture, and killing, of sea turtles in trawl nets of U.S. shrimpers.

Despite the eventual deployment of nearly a dozen types of turtle excluder devices (TEDs), some of the best models formulated *without* using any federal funds, there have been years of political and legal foot-dragging, stone-walling, infighting, and other political maneuvering to stop legislation for mandatory use of TEDs on shrimp trawls. Consequently, incidental captures continued, as did *preventable* deaths of large numbers of turtles, many of which were breeders and/or the highly endangered Kemp's ridley turtle. (It is also noteworthy that this fishery is government subsidized, targeted on a luxury product, over-fished, and destructive to other valuable fisheries resources). Remarkably, the estimated number of turtles killed annually by U.S. trawlers exceeds—by a generous margin—the estimated number of turtles taken yearly throughout the entire Western Atlantic system by subsistence fishermen in the Caribbean and east coast of Latin America. The effect of the TED fiasco south of the Rio Grande has *not* been increased credibility of conservation initiatives exported from the USA.

As has been known for years to turtle biologists, incidental capture of these reptiles in shrimp trawls is a major source of mortality: unsustainable to the respective breeding populations. The use of turtle excluder devices is an effective way to reduce this mortality, without undue impact on the trawl fishery. The magnitude of the problem of incidental capture cannot be overemphasized, and this book provides critical information prompting a long-delayed, responsible political solution. On 1 March 1990, legislation for mandatory use of TEDs in the Gulf of Mexico finally went into effect for U.S. shrimpers.

Although the title is "Decline of the Sea Turtles: Causes and Prevention," the very specific focus on TEDs, as described above, is clear from the structure and contents of the book: Executive Summary; Introduction; Biology; Population Trends; Distribution of Sea Turtles in U.S. Waters; Natural Mortality and Critical Life Stages; Sea Turtle Mortality Associated with Human Activities; Conservation Measures; Conclusions and Recommendations; References; and Appendixes A–J. The appendixes are: A) Endangered Species Act Amendments of 1988; B) Interim Report, Committee on Sea Turtle Conservation; C) Illustrations of Turtle Excluder Devices; D) Aerial Survey Data of Sea Turtles in Fishing Zones; E) Sea Turtle Stranding Data; F) Shrimp Fishing Effort; G) Annotated and Chronological List of Educational Efforts on TEDs for Fishermen by National Marine Fisheries Service; H) Annotated and Chronological List of Educational Efforts on TEDs for Fishermen by Sea Grant; I) Newsletters and Notices Pertaining to TEDs; and J) Biographies of Committee Members.

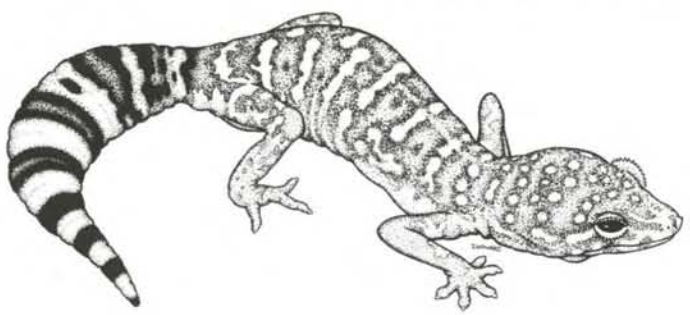
The Committee on Sea Turtle Conservation, directly responsible for the book, included specialists in several fields pertinent to the issues, and four of the best informed and most capable sea turtle biologists in the world: hence, the reader can hardly have low expectations. For that reason this reviewer feels impelled to

bias this review toward the major disappointments, and save limited space by simply stating that there is a great deal of good information and synthesis in the book. Anyone interested in marine turtles would benefit from reading it, as would people involved in marine fisheries with politically volatile activities.

For a book as large and complex as this, it is not surprising to find problems of form. Still, it would have provided a more serious and useful depiction of U.S. turtles to have used some of the many excellent illustrations which are now commonly seen at turtle conferences, instead of the stylized cartoons in Fig. 2-1 (p. 22). For a review, it is astonishing how much information is presented without any citation of source.

A lucid warning comes from the title page: no author's name appears, but instead there is a giddy series of organizations, including one committee, two boards, a commission, and a council. Clear evidence that the book was manufactured by committees, etc. can be seen in a varying style and inconsistent treatment of topics between chapters and comparable sections. The subject of sea turtle species is a woeful example: in the preface, we are informed that the task of the committee was to provide information on the five species which occur within U.S. waters; yet, six species are listed in the table of contents. On pages 21 and 23 we are told that there are a total of eight species of sea turtles—which can only be true if one accepts that there are two species in the genus *Chelonia*: the green turtle, *C. mydas* and the east Pacific black turtle, *C. agassizii*. However, on page 16 *Chelonia mydas* is described as including the east Pacific populations in México (thus, negating the validity of *C. agassizii*). A meticulous, critical review and final revision of the entire manuscript would have done wonders to giving the work the final polish which it merits.

The reader will be startled by the levels of Yankee egocentrism. This book is *not* about "Decline of the Sea Turtles," nor even about turtles in the USA. It is clearly focused on the eastern USA and neighboring waters of the Caribbean and Gulf of Mexico. The reader not acquainted with the subject would hardly guess from reading the book that there is a major area of Pacific waters under U.S. jurisdiction, where the management and conservation of sea turtles is problematic. Furthermore, outside of official U.S. jurisdiction is a vast kaleidoscope of sea turtle problems involving international relations, political and economic conundrums, as well as disparate national laws, cultures, habits, technologies, and traditions, to say nothing of varying government and civil responses to these problems. There is an urgent need to respond to the decline of sea turtles in these regions, but the book simply does not consider them. The ambitious title is not germane to the text.



However, more disturbing is a statement about the olive ridley turtle, a species rare in U.S. waters. We are informed (p. 41) that "its status and future are not in the main, a direct United States responsibility." Are we to believe that U.S. foreign policy, arms sales, biocide sales, global environmental pollution, and economic and cultural domination have no effect on natural resources 200 miles offshore of the east coast of the USA?

It is made perfectly clear in the Executive Summary (p. 2) that the book does "not analyze social and economic issues related to sea turtle conservation." That the various academic committees, boards, and commissions thought that they could realistically analyze the causes, and prescribe preventions, of declines of sea turtles from within this limited horizon is frightening. Anyone struggling outside of the rarefied atmosphere of higher academia to make biological conservation and sustained utilization a reality, will still have to invest considerable time and effort in educating the educated. The best biological information in the world will alone not save a single population, species, or ecosystem; biological conservation is a sociopolitical activity, not science.

In summary, a different title would have avoided, or greatly reduced, many of the above problems. A more restrictive, specific, even more humble, title might have been: "A contemporary review and synthesis of biological information on sea turtles along the Atlantic and Gulf of Mexico coasts of the USA, with special reference to the problem of incidental capture in shrimp trawls."

Note added in press: The above review was written in 1993, for *Oryx*, which later suspended publishing book reviews. At that time I naively assumed that with the long overdue legislation of 1 March 1990, TEDs would finally be implemented, and that the incidental catch—at least in U.S. waters—would at last be brought under control. Indeed, it was a U.S. congressional mandate, at the behest of congressional opponents of TEDs, which resulted in the National Research Council being commissioned to write *Decline of the Sea Turtles*. Never underestimate the nearsightedness and narrow-mindedness of recalcitrant politicians! Nor the greed and irresponsibility of the commercial fishing industry! As of the summer of 1995, the incidental capture issue in U.S. Gulf states is far from being solved; the political solution, with the use of TEDs, seems more mired in avaricious politics than ever. Meanwhile, the biological information, pointing to the urgent need for a rapid and lasting resolution, only accumulates faster (Gallaway et al. 1995. Sea Turtle and Shrimp Fishery Interactions—Is a New Management Strategy Needed? Texas Shrimp Assoc., LGL Ecological Research Associates, Inc., Bryan Texas, 142 pp.; Shaver 1995. Marine Turtle Newsletter 70:2–4). This underlines the conclusion that biological conservation is politics, not science. And south of the Rio Grande, the credibility of the U.S. in environmental matters continues to slide backward. An interesting review of the issue is Weber et al. (1995. Delay and Denial: A Political History of Sea Turtles and Shrimp Fishing. Center for Marine Conservation, Washington, D.C., 46 pp.).—*JF, 24 August 1995.*

Male *Coleonyx switaki* (Barefoot Gecko). USA: California: San Diego Co. Illustration by Thad A. Howard.

Amphibians of Washington and Oregon, by William P. Leonard, Herbert A. Brown, Lawrence L. C. Jones, Kelly R. McAllister, and Robert M. Storm. 1993. Seattle Audubon Society. 168 pages. Softcover. ISBN 0-914516-10-8 US $9.95. Available from Seattle Audubon Society, 8028 35th Avenue NE, Seattle, Washington 98115, USA ($2.50 shipping and handling).

Another regional field guide. Do we need it? Does it fill a vacant niche? Does it work? In this case, the answer to each of these questions proves to be an unqualified "yes." This is not to take anything away from the two other field guides which cover the states of Washington and Oregon (Nussbaum et al. 1983; Stebbins 1985). They too are excellent resources, and along with this new book, represent a fine herpetological natural history library for these two states.

This field guide represents the most recent addition to the Trailside Series published by the Seattle Audubon Society, a series "designed to enhance the knowledge and appreciation of natural history in the Northwest and assist in the conservation of species and habitats." In keeping with this theme, the authors state that their book is designed simply to be used to assist in identifying the amphibians of Washington and Oregon. Their target audience includes "teachers, students, naturalists, professional field biologists, and lay-persons alike," a broad group indeed!

The diversity of the intended audience is reflected in the diversity of the authors themselves and the organizations sponsoring this publication. The five authors represent five different institutions and agencies (two universities, two state agencies, and one federal agency). An equally diverse group of seven societies, state agencies, and federal agencies sponsored this publication. I believe this level of cooperation reflects two things: first, a superb effort by Bill Leonard in organizing this many individuals and groups, and second, a growing appreciation by more than just small groups of academics and enthusiasts that amphibians are important components of ecosystems as well as fascinating creatures in their own right.

The bulk of the text (132 pages) is devoted to species accounts. Of the remaining sections making up the book, three (Overview of Amphibians, Notes on Salamanders, and Notes on Frogs and Toads) give the reader some basic biological knowledge of these animals. Another section effectively discusses the current state of affairs in amphibian systematics and taxonomy. In the section entitled Conservation and Regulations, the loss of amphibian habitats and species is emphasized, and the current legal status and resulting collecting regulations are given for those species most affected. For those less familiar with the biology of these animals, figures showing general features of salamanders and frogs are provided along with a very helpful glossary. A checklist of species is also provided, and four pages of references are given.

The 33 species accounts are consistent in writing, organization, and level of information, not an easy editorial task when dealing with five authors. Each account begins with a description of the characteristics useful in correctly identifying the species of salamander or frog. Key characteristics are highlighted in bold type, a very helpful feature, especially when juggling a specimen in the field. A section follows with the descriptions of species with similar appearance, helpful especially for those groups (e.g. genus *Plethodon*) with several species exhibiting only minor morphological differences. Distribution information is accompanied by a map showing the areas where the species is known to occur. County boundaries are marked. Life history information, habitat association, diet, behavior, and breeding biology are summarized in a single section. A final component of each account is a section containing additional information (e.g., taxonomy, subspecies, population status, anecdotal information) of potential interest to the reader.

This book succeeds on several fronts, but the most obvious is the high quality of the photographs. Unlike those used in some field guides, these are clear, crisp, close-up shots in which the details of structure and color can be seen. In addition to quality, we are also treated to quantity. Each account is accompanied by three to six photos showing not only a dorsal view of the animal, but usually a ventral view, as well as larvae, variants, egg masses, and habitat. A number of individuals are responsible for these wonderful photos, but the vast majority are the work of Bill Leonard.

While most of the text beyond the species accounts is standard field guide fare, two sections deserve mention. First, the section concerning taxonomy is well done and up to date. Taxonomy is described as a field undergoing its own changes and producing much new understanding of relationships and classification as the field evolves. It is a gentle introduction to those with little or no understanding of this area of biology and attempts to quiet concerns about the "splitting" of species and the seemingly continual addition of new names attached to subcomponents of well known taxa.

The second section of note concerns conservation of amphibians and regulation of their capture. Here the authors discuss the apparent decline in amphibian populations around the world and in the Pacific Northwest. Readers are informed of federal and state regulations concerning collection of amphibians, and those species whose populations are of primary concern are noted. This information supports the strong conservation ideal evident in the introduction, where readers are encouraged to handle any captured animals with care, to return them to where they were found, and to be sensitive to their habitats. The message: amphibians are best appreciated in their natural setting.

There is little here to criticize. Some might like to have a key to the amphibians with which to aid species identification, but I believe that it would actually be little used by those who will use this book the most. I personally would like to have seen a more extensive bibliography with references specific to each taxa cited in association with each account, but again, many of the targeted audience might not feel such a need.

All in all, this is an excellent book. The authors have not only successfully met their goal of assisting a diverse audience in identifying the amphibians of Washington and Oregon, but have gone well beyond that by presenting the most up to date information concerning the natural history, taxonomy, and conservation of these animals. In addition, they have produced a field guide which does not compete with, but rather complements the other volumes available for this region. While it may not be as exhaustive as Nussbaum et al. (1983) or have the breadth of Stebbins (1985), it already is being used by amateurs and professionals alike and will be for years to come.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1996 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. All members receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Karen L. Toepfer, SSAR Treasurer, P.O. Box 626, Hays, Kansas 67601–0626, USA. Telephone: (913) 623-4258; Fax: (913) 625-8890; e-mail: fmkt@fhsuvm.fhsu.edu.

HERPETOLOGICAL REVIEW (ISSN: 0018-084X) is published quarterly in March, June, September and December by the Society for the Study of Amphibians and Reptiles at 303 West 39th St., Hays, KS 67601-1518. Application to mail at 2nd Class Postage rates is pending at Hays, Kansas with additional entry offices. **POSTMASTER:** Send address changes to *HERPETOLOGICAL REVIEW*, P.O. Box 626, Hays, KS 67601-0626.

Future Annual Meetings

1996 — University of Kansas, Lawrence, Kansas, USA, 24–29 July (Linda Trueb, Chair).
1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July (Theodore Pietsch, Chair).
1998 — University of Guelph, Guelph, Ontario, Canada, 16—22 July (James P. Bogart, Chair).

1996 Annual Meeting
Society for the Study of Amphibians and Reptiles
39th Annual Meeting

24 – 29 July 1996
The University of Kansas, Lawrence, Kansas, USA

Keynote Lecture: To be announced.

Symposium: "A Tropical Natural History: Essays in Honor of William E. Duellman." *Organizers:* Darrel Frost (American Museum of Natural History) and John D. Lynch (The University of Nebraska).

Symposium: "Diversity of Approaches to Amphibian and Reptilian Systematics." Participants restricted to graduate and post-doctoral students. *Organizers:* Daniel J. Meinhardt and Joseph R. Mendelson III. *Contact:* Joseph R. Mendelson III, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA; Telephone: (913) 864-3439; Fax: (913) 864-5335; E-mail: sapo@falcon.cc.ukans.edu

Symposium: "Population Status and Conservation of Amphibians." Sponsored by the US DAPTF. *Contact:* Michael J. Lanoo, Muncie Center for Medical Education, Indiana University School of Medicine, MB209, Ball State University, Muncie, Indiana 47306, USA; Telephone: (317) 285-1050; Fax: (317) 285-1059; E-mail: 00mjlanoo@bsuvc.bus.edu

Workshop: "Herpetological Collections: Funding, Growth, and Management." Guest speakers will include Dr. Meredith Lane, Program Officer for the National Science Foundation. Other speakers will provide information on conservation project grants from other organizations such as the Institute for Museum Services and the National Institute of Conservation. Workshop will include description of planning process for, and in-depth tour of, the new state-of-the-art Fluid Collections Facility. *Contact:* John E. Simmons, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA; Telephone: (913) 864-3342; Fax: (913) 864-5335; E-mail: jsimmons@kuhub.cc.ukans.edu

Oral and Poster Sessions: Several concurrent sessions each day.

Student Paper Awards: Seibert Prizes to be awarded to the two best student-presented papers at the meeting ($250 first prize, $150 second prize).

Dyche Hall, home of the Natural History Museum.

Herpetological Travelogue Slide Shows: Profusely illustrated lectures of exotic amphibians and reptiles and their habitats.

Multimedia Presentations: "HERPS OF THE WEST" and "AMPHIBIANS OF THE APPALACHIANS" by David Dennis and Eric Juterbock; "HERPETOLOGICAL NAMESAKES" by Kraig Adler and David Dennis.

Declining Amphibians: Annual board meeting of the IUCN/SSC Declining Amphibian Populations Task Force.

Social Activities: Welcoming Social, Auction, Barbeque Picnic, Graduate Student Social (including herpetological trivia quiz with prizes).

Art and Photographic Exhibit: Featuring herpetological art and photographs.

Rare Book Exhibit: A special exhibit, "THE SLIMY TOETH," by Sally Haines in the Spencer Research Library, featuring 16th and 17th century books dealing with herpetology.

The SSAR meetings will be held in the Kansas Union.

Live Exhibit: Featuring amphibians and reptiles from Kansas. Presented by the Kansas Herpetological Society.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

KU Publications: Greatly discounted prices on herpetological publications (Occasional Papers, Miscellaneous Publications, Monographs, and Special Publications) of the KU Natural History Museum.

Venue: All sessions, exhibits, meetings, and most social events will be held in the Kansas Union located adjacent to the Natural History Museum; the picnic will be held at nearby Clinton Lake (bus transportation provided).

Costs: Preregistration $125 regular, $90 student; late registration fee after 1 June $170 regular, $125 student; companion (social only) preregistration $30, after 1 June $50. Lodging in dormitory: $100 person/5-day package (double occupancy; includes breakfast each day and 3 dinners) and $140 person/5-day package (single occupancy; includes breakfast each day and 3 dinners). Buffet lunch provided at meeting site—$30 for 5 days. Owing to lack of nearby local restuarants and difficulty securing convenient campus parking, all participants are encouraged to purchase lunch-ticket package so that they can eat at the meeting site.

Further Details: Meeting Announcement/Call for Papers will be mailed to all North American members of the SSAR in March 1996, or upon request from Cathy M. Dwigans, Academic and Professional Programs, Continuing Education, The University of Kansas, Lawrence, Kansas 66045, USA; telephone (913) 864-3284; Fax (913) 864-5074. Chairperson of Local Committee: Linda Trueb, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA; Telephone: (913) 864-3342; Fax:(913)864-5335. E-mail: Trueb@kuhub.cc.ukans.edu

SSAR BUSINESS

A Letter from the SSAR President

Dear Fellow Members:

The Society's Board of Directors considered a number of important matters at its recent meeting in Boone, North Carolina. (See Secretary Eric Juterbock's report on the meeting for further details). Several of those matters merit additional explanation, and none more so than the increase in dues for student members.

Last year the Board voted to raise dues, for the first time in many years, for all categories except students. That decision was an attempt to hold down costs for our valued student members while at the same time meeting the gradually increasing costs of operation of the Society and the costs of implementing new and expanded programs. Although the Board was able to hold off an increase in student dues for one year, a review of our budget this summer made it clear that to do so any longer would not be prudent. Faced with an unanticipated rise in postal costs and other unexpected increases in operating expenses, the Board voted to increase student dues by $5.00, thereby bringing student membership back in line with other categories of members and avoiding a continuing structural deficit in the Society's budget. No other membership categories were affected this year.

Sensitive to the effect of such a dues increase, the Board also voted to extend to our student members a one-time discount on all books and other monographic publications of the Society. Between now and 1 May 1996 student members may purchase any society publications (other than back issues of journals and books presently offered at prepublication prices) at a 20% discount. We hope that many students will take advantage of this valuable offer and that it will offset any inconvenience associated with the rise in student dues. Of course, even at the new rate, the Society continues to provide extraordinary value to student members. In addition to receiving the *Journal of Herpetology* and *Herpetological Review*, students are always eligible for members' prepublication discounts. The Society also assists many students through its Grants-in-Herpetology program, and it recently launched its highly successful program of travel awards to students attending the Society's annual meeting. Most recently, the Board approved a project proposed by a student member to produce a directory of funding sources for herpetological research. With these many benefits, the Board of Directors hopes that our valued student members will not only renew their own memberships but will encourage their herpetological colleagues to join them.

Among its other actions, the Board continued to promote the conservation efforts of the Society in a number of ways. This year the Society contributed $5,000 of the proceeds from the annual auction to assist the Declining Amphibian Populations Task Force, an international organization that has evolved within less than five years to take a leadership role in the study of amphibian populations. The Society also looks forward in 1996 to the first issue of our new series *Herpetological Conservation*.

The Society for the Study of Amphibians and Reptiles has always encouraged the active participation of its members. That participation has recently been made even easier with the establishment of a home page on the World Wide Web. On our Web site, members can find announcements, addresses of officers, the contents of upcoming issues of our journals, and other useful information. Of course, members are also encouraged to communicate directly with the officers if they have ideas for strengthening the programs of the Society.

Best regards,

ALAN H. SAVITZKY
President

About our Cover

Hypsilurus boydii, Boyd's forest dragon, is an arboreal agamid found only in the rainforest of far northern Queensland, Australia. Until recently, very little was known about this species and the few published accounts are anecdotal. The majority of the following information is based on unpublished research currently being conducted by **Geordie Torr** at James Cook University, Townsville, Australia.

Forest dragons are sexually dimorphic; males attain a snout-vent length of ca. 165 mm compared to 150 mm in females. Reproduction is seasonal, with females laying 1–5 eggs in a shallow nest in a sunny area between September and December. Lizards living in high elevation areas lay fewer, larger clutches of larger eggs than their low elevation conspecifics.

These diurnal lizards feed almost exclusively on invertebrates, with ants, beetles, and earthworms amongst their most common prey items. Although most often seen perching at around eye-height on small trees, the use of spool-tracking has revealed daily terrestrial movement on the order of 50–100 m per day. At night, forest dragons can often be spotlighted sleeping on trees. Larger lizards generally sleep vertically on the trunk but hatchlings, juveniles, and small females often sleep in a horizontal position on branches, their head pointing towards the trunk. This behavior is very similar to that exhibited by some species of *Anolis* (Clark and Gillingham 1990. Anim. Behav. 39:1138–1148).

Forest dragons appear to be thermoconformers and daily activity is probably regulated by light intensity rather than temperature. Lizards became active at dawn and cease activity at dusk. During winter, forest dragons "disappear," moving up into the lower canopy and becoming inactive, descending infrequently to feed.

The lizard on the cover is an adult male, photographed in situ at one of Geordie Torr's study sites. It was photographed with a Bronica medium format camera, using a standard 75 mm lens and two flash units. The photograher is **John Weigel**, who, along with wife Robyn operate the Australian Reptile Park, just north of Sydney. The Park was established in 1958 by the late Eric Worrell. It currently maintains the largest collection of native reptiles in Australia and is the sole supplier of snake venoms used in the production of Australian antisera. John is an expatriot American, and while a student at the University of Colorado he took Comparative Anatomy 101 from Hobart Smith—but admits to receiving a "C." He is an Australian citizen now, and an active supporter of amateur herpetology in his adopted country, having lobbied strongly for loosening of regulations constraining amateur herpetological activities. He has published a field guide to snakes of southeastern Australia, a book on the captive husbandry of Australian reptiles, and his photographs are popular inclusions in most books that picture Australian reptiles and amphibians. He is currently working on a photo-introductory book on Australian herps.

Separation and imaging of Weigel's photo is the work of **Jim Bridges** of Herpeto Inc., Hollywood, Florida, USA.

1995 Annual Meeting: Boone, North Carolina

Boone, North Carolina, from 8 to 13 August 1995, served as the site of the 38th annual meeting of the SSAR. Appalachian State University, with Wayne Van Devender chairing the Local Committee, served as host to the more than 500 attendees. The large size of the meeting was no doubt aided by the grand venue, a conference center located on a small cloud-shrouded mountain in the heartland of plethodontid salamanders. and the Local Committee cooperated by ordering sufficient late-afternoon rain showers that it never got too hot and was conducive to observing salamanders.

Appetizer

For those of our group who could not possibly start an Annual Meeting without a brief Board Meeting, our start to the Boone fete was the annual meeting of the SSAR Board. We met for seven and one half hours on the 8th, and (Board addicts that we were, we could not bear to let go for another day) we reconvened for one and half hours (and pizza) to work out the 1996 budget on the 9th. Not considering the overnight recess, this was still one of the longer Board Meetings of recent years. All of the Board members and all but one of the officers were in attendance by lunch time, as were half of the editors and committee chairs. An unusually large number of members were also in attendance, so the meeting was one of the better attended recent Board Meetings; most made it back as we reconvened for the budget discussion the next day. Business of the meeting was summarized at the Business Meeting (below).

Meat and Potatoes

The 38th Meeting officially opened at 0900 h on 9 August, in Broyhill Hall at the Broyhill Inn (site of most meeting events), with welcoming remarks from Wayne Van Devender. Wayne also announced that Matjaz Rojc, of Ljubljana, Slovenia, donated to the meeting a supply of the new Slovenian coin imprinted with *Proteus* (the only salamander on a coin!); Wayne later distributed these coins to attendees. R. Clinton Parker, Senior Associate Vice Chancellor for Academic Affairs at ASU, then welcomed us to the University. After SSAR President Savitzky issued one more welcome and mentioned plans for the Third World Congress of Herpetology, in Prague in 1997, Linda Trueb, Co-Chair of the 1996 Annual Meeting Committee, invited us all to next year's meeting at the University of Kansas, in Lawrence (see announcement on pages 165–166). There followed the Plenary Address, after which the assembled multitudes were collectively photographed.

Judy Stamps (University of California at Davis) presented "Territorial Behavior: Testing the Assumptions." Dr. Stamps presented evidence about how juvenile settlers are attracted to conspecifics and how inter-male competition and sexual size dimorphism are related to the spatial distribution patterns of adult females. These results were drawn from her field experiments with West Indian *Anolis*.

Between 1330 h on 9 August and 1600 h on 12 August, 210 authors presented 130 contributed papers in 12 sessions. In three symposia, Regional Herpetological Societies, Evolutionary Patterns of Amphibian Development, and Eastern Rattlesnakes, 48 authors presented 40 papers. Three poster sessions included 75 posters by 128 authors. A session called "Conservation Issues in Herpetology" was attended by many on the evening of the 8th. Ken Dodd (National Biological Service) moderated the discussion, which included Alison Haskell (U.S. Fish and Wildlife Service), Ron Heyer (National Museum of Natural History), and Mike Lannoo (Declining Amphibian Populations Task Force). Several dozen herpers participated in a "Herp Photo Workshop" conducted by Dave Dennis and Eric Juterbock on the afternoon of the 9th.

The Business Meeting was conducted on Saturday, 12 August, between 1630 and 1715 h in the Bernhardt Lounge at Broyhill, and attracted a crowd of over 60 officers and members even though there was a concurrent discussion group concerning the Declining Amphibian Population Task Force (DAPTF). In calling the meeting to order, President Savitzky noted that he had worried about forgetting the famous "SSAR Presidential Gavel" ever since it was entrusted to him by then-President Lynne Houck last August.

President Savitzky reported on a number of items of business announced or conducted at the Board Meeting. Our most significant business this year was to modify the dues structure. Last year all classes of members except students received a small increase; this was postponed but not prevented forever for students. With the increases in SSAR activities and in postal rates, we found it necessary to increase student dues by $5 effective in 1996. The Board did approve offering students a 20% discount on all individual SSAR publications until 1 May 1996. The Board also granted the DAPTF $5000 to aid their work. SSAR is also investigating collaborative projects involving audio products, which could conceivably yield proceeds for DAPTF as a long-range source of funds. There is a need for mass marketing advice. President Savitzky has formed an ad hoc Committee on International Cooperation, chaired by Marty Crump, and including Oscar Flores, Tyrone Hayes, Roy McDiarmid, and Ted Papenfuss. Their charge is to investigate how SSAR could aid herpetologists in other countries to gain access to such items as research supplies, equipment, and bibliographic materials. George Pisani has put together a World Wide Web page (Internet) for SSAR and will be adding information. The Student Travel Awards Committee, coordinating their second annual fund-raising auction at Boone, will undergo a change of leaders, as founding student co-chair Dawn Wilson is retiring; she recommended John Lee as her successor. The Committee made 10 travel awards of $200 each to students attending the Boone meeting.

Treasurer Karen Toepfer reported that 1994 expenses paid to date, $165,478, were balanced by 1994 income of $186,061. There should be some increase in expenses for 1995, due to the increase in postal rates and the enlargement of *Herpetological Review*. At the time of the meeting, there were 2339 members, approximately 150 more than this time last year; 34 new members joined at Boone.

Past-President Houck reported that she had encouraged students to organize and conduct a students-only paper session, and one on amphibian developmental biology was accomplished this year. The *Journal of Herpetology* is in good shape and 1995 will be one of the largest ever volumes (for number of pages). Submissions remain high and the Table of Contents will be added to SSAR World Wide Web page. Editor Bob Hansen noted that *Herpetological Review* exists to serve the society for information exchange. He also pointed out all of the changes implemented this year. The *Catalogue of American Amphibians and Reptiles* remains in good shape but still needs authors for accounts of North American species. The subscription rate increased $5 for 1996. Kraig Adler, Editor of *Facsimile Reprints in Herpetology* and *Contributions to Herpetology*, announced that the "Captive Management and Conservation of Amphibians and Reptiles," published in December 1994, has already sold 1500 copies. "Lizards of Australia and New Zealand," by J. E. Gray and A. Günther, was issued in June 1995 and "The Herpetological Papers of Wilhelm Peters" in September 1995. Through 1996, he expects to publish the classic "Herpetology of Japan," by Leonhard Stejneger, and three new books: "Field Guide to Amphibians and Reptiles of the West Indies," by Blair Hedges; "Contributions to West Indian Herpetology," the 1994 symposium edited by Bob Powell and Robert Henderson; and "Lizards of Iran," by Steven Anderson. In 1996, *Herpetological Circulars* will issue the 4th edition of "Standard Common and Current Scientific Names for North American Amphibians and Reptiles," compiled by J. T. Collins, on behalf of SSAR. *Herpetological Conservation* Editor Steve Corn expects to issue the first volume in the series, the "Canadian Amphibian Decline Symposium," edited by David Green, in 1996.

Awardees for GIH grants and the Kennedy Student and Seibert Awards were noted (see p. 170). Future meetings in Lawrence, Kansas (24–29 July 1996), Seattle (26 June–2 July 1997), and Guelph, Ontario (16–22 July 1998) were announced. Regional Societies Liaison Marty Rosenberg reported that the Regional Societies Symposium, covering such topics as marketing, education, and research, had nine papers. Next year they have tentative plans to sponsor a symposium focused on local conservation efforts.

Nominations for election to SSAR office for 1996 were announced. President-elect: Henry Mushinsky and Steve Tilley; Secretary: Ellen J. Censky; Treasurer: Karen Toepfer; Director (Class of 1998): John Iverson and John Simmons; and, Director (non-U.S., Class of 1998): James Bogart and Diane Secoy. After Bob Aldridge nominated Randy Krohmer for Director, Kraig Adler moved (Bob Hansen second) to close the nominations; motion passed and the slate was accepted. Lynne Houck then read the resolutions (see below). With no new business added from the floor, Henri Seibert moved (Lynne Houck second) to adjourn, and President Savitzky adjourned us until 1996 in Lawrence.

Desserts

No annual meeting would be complete without the myriad social and other activities after the papers are done for the day. Chairman Van Devender and his crack committee did a great job of planning such relief for us! In addition to the excellent feed that was the luncheon buffet at the Broyhill, and such fine local food as barbecue, catfish, and southwestern cuisine, there was limitless food at the "welcome social" on the evening of the 9th and the SSAR auction on the evening of the 12th. There was also the off-campus barbecue and social the evening of the 10th, complete with music and dancing.

A large room housed the numerous exhibitors, who, among such other items as tee shirts, art work and research equipment, had more herp books than anyone could expect to read in a lifetime. It took two rooms in the science building to house the live herp exhibit, where attendees gathered daily to photograph the local herpetofauna (as well as a few exotics). A herp art exhibit was located in Broyhill. There was also a student-only program and social on the 11th.

The now traditional entertaining/educational events expected at SSAR meetings did not disappoint, either. I stopped counting at 300 members of the audience for the multi-media event on the evening of the 11th. "Amphibians of the Appalachians" and "Herpetology of the West" by Dave Dennis and Eric Juterbock and "Herpetological Namesakes" by Kraig Adler, Dave Dennis, and Eric Juterbock were well received. The grand finale, on the evening of the 12th, began with the President's Travelogue, which attracted a standing-room-only crowd that I could not begin to count. Julian Lee presented "Amphibians and Reptiles of the Lowland Maya Area," Aaron Bauer, "The Herpetofauna of the Southern African Arid Zone," and Wayne Van Devender, "Amphibians and Reptiles of Australia After the World Congress." Guaranteed to stimulate more trips to view and photograph herps in the coming years. Of course, the SSAR Auction rounded out the events of the week. With food and our favorite beverages, a huge crowd gathered to acquire those "must-have" items auctioned off by Joe Collins, who also announced the winners of the Student Travel Silent Auction. Over $5,000 was raised. Some of us were even able to partake of one of the several field trips to herp hot spots like Grandfather Mountain, Linville Gorge, and Yonahlossee Road before leaving town on the 13th.

Respectfully submitted by J. Eric Juterbock, SSAR Secretary.

1995 SSAR Resolutions

Honoring Outgoing SSAR Officers and Editors

WHEREAS the following individuals have given freely of their time, skills, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year; and,

WHEREAS they have been therefore instrumental in advancing the Society's goals and furthering its growth as an international scientific society; and,

WHEREAS SSAR is dependent upon the generosity of these persons and those who have gone before them, and is greatly indebted to them for their fine efforts in its behalf;

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles urges these persons not to ride off into the sunset, but rather to continue to be available, with or without official titles, as resources to guide those who follow; and,

RESOLVED FURTHER that the Society offers its most sincere thanks to the following persons who have served in these capacities:

ROBIN M. ANDREWS—Director
A. DALE BELCHER—Chair, Grants-in-Herpetology Committee
MARTHA CRUMP—Chair, 1994 Nominating Committee
MAUREEN A. DONNELLY—Grants-in-Herpetology Committee
THOMAS H. FRITTS—Immediate Past-President
J. WHITFIELD GIBBONS—Co-Chair, 1994 Local Committee
DAVID L. HARDY, Sr.—Elector
LYNNE D. HOUCK—President
RANDY JENNINGS—*Herpetological Review* Section Editor
JOSHUA LAERM—Co-Chair, 1994 Local Committee
SAM MCDOWELL—*Journal of Herpetology* Editorial Board
MARY MENDONÇA—Member, 1994 Nominating Committee
CHARLES W. PAINTER—Grants-in-Herpetology Committee
STEVE PERRILL—Member, 1994 Nominating Committee
STEVE REILLY—Chair, 1995 Nominating Committee
ERIC M. RUNDQUIST—*Herpetological Review* Section Editor
BERN W. TRYON—Director
DAWN S. WILSON—Grants-in-Herpetology Committee

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 11 August 1995, at its Annual Business Meeting.

Thanking The Local Committee

WHEREAS the southern Appalachian Mountains harbor a most diverse and interesting salamander fauna, and provide an excellent setting for herpetological meeting; and,

WHEREAS the Society for the Study of Amphibians and Reptiles is pleased to be able to hold its 1995 Annual Meeting in such a setting; and,

WHEREAS Robert Wayne Van Devender and the rest of the Local Committee have done a fine job in managing this meeting's many responsibilities; and,

WHEREAS the officials of Appalachian State University have cordially made their campus available to us.

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and

Reptiles extends its most sincere thanks to the members of the Local Committee, and to all involved in making this meeting a success.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 11 August 1995 at its Annual Business Meeting.

1994 SSAR Budget Report

Budget Category	Amount Allocated	Amount Spent
Annual Meeting (Keynote Speaker)	$500	500.00
Catalogue AA&R	8,000	8,231.13
Contingency Fund	3,000	0
Contributions to Herpetology	15,000	8,348.33
Emergency & Special Projects Fund	5,000	1,695.25
Facsimile Reprints in Herpetology	2,000	0
Grants-in-Herpetology	1,000	2,512.00
Herp Circulars	2,800	2,897.02
Herpetological Conservation	0	1,153.75
Herpetological Review (including editor's expenses)	18,000	20,870.97
Journal of Herpetology (including editor's expenses)	64,342	61,244.15
Publications Secretary	15,000	14,241.50
Secretary	1,800	509.37
Treasurer	7,700	9,490.83
Total 1994 Budget	**$144,142.00**	**$131,694.30**

Kennedy Student Award Committee Annual Report — 1995

The Kennedy Award Committee has completed its work for Volume 28 of the *Journal of Herpetology*. The Committee has selected "Growth Rate and Survival in Relation to Relative Head Size in *Vipera berus*" by Anders Forsman. Mr. Forsman carried out this work as a doctoral candidate in the Department of Zoology, Uppsala University, Uppsala, Sweden. The dissertation supervision was directed by Staffan Ulfstrand. After a year of postdoctoral studies with Richard Shine in Australia, Anders Forsman is back in the Department of Zoology at Uppsala University as an Assistant Professor. He is currently investigating color polymorphism in adders, lizards, and grasshoppers.

Twenty manuscripts were in competition this year. The Committee noted the high quality of the submitted papers.

KEN R. MARION, Chair
Kennedy Student Award Committee.

Seibert Award Winners for 1995 Announced

The fourth annual Seibert Awards were presented at the 38th Annual Meeting of the SSAR in Boone, 8–12 August 1995. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). The awards recognized outstanding student presentations at the annual meeting. There were 36 presentations eligible.

The winners.—Steven Poe (First Award), Department of Zoology and Texas Memorial Museum, University of Texas at Austin ("Phylogenetic systematics of the Crocodylia: An integrative approach"); Richard E. Anderson (Second Award), Department of Biological Sciences, Southeastern Louisiana University ("Systematics of the polytypic species *Coluber constrictor*").

Honorable Mention (in no particular order).—J. R. Bodie (Savannah River Ecology Lab, University of Georgia), K. R. Smith (Department of Biological Sciences, Southeastern Louisiana University), and V. J. Burke (Savannah River Ecology Lab, University of Georgia): "A comparison of diel nest temperature and nest site selection for two sympatric species of freshwater turtles." Dana A. Soehn and Edwin D. Michael (Division of Forestry, West Virginia University): "Salamander abundance in small clearcuts."

The judges were Ellen Censky (Carnegie Museum), Rafael de Sa (University of Richmond), Lynnette Sievert (Maryville College), and Norm Scott, Chair (National Biological Service).

Items Needed for SSAR Auction

Joe Collins will be conducting the SSAR auction during the annual meeting at the University of Kansas in July 1996. All proceeds from the auction go to the SSAR treasury, and help to continue the production of diverse publications and services which has made the SSAR the largest professional herpetological society in the world. Items of value as well as those that lend themselves to humor are always welcome. Joe is skilled at removing large quantities of cash from auction participants through the judicious use of beer and plastic. Anyone wishing to donate auction items in advance should send them directly to: *Joseph T. Collins, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA.*

SSAR Student Travel Awards

The first annual SSAR Student Travel Awards were presented at the SSAR meeting in Boone, North Carolina. The winners were: Christopher Binckley, Paul Buttenhoff, Brian Butterfield, Michael Gallagher, Andrew Gluesenkamp, Karen Graham, Steve Johnson, Kimberly Naklicki, Karan Schnuelle, and Sue Simon. Congratulations to all.

The SSAR Student Travel Awards Committee wishes to thank the following people for their donations to the Frameable Art Silent Auction: Kraig Adler, Robert Aldridge (SSAR), Ronald Altig, Patty Barber, Bern Bechtel, Betty Bechtel, Martin Capron, Caribbean Conservation Corp., Pablo Delis, David Dennis, Kenneth Dodd, David Hardy, Dan Holland, Jim Horton, Barbara Kermeen (AVM), Dan Keyler, Julian Lee, Ernie Liner, J. Kelly McCoy, Roy McDiarmid (USNM), Samuel McDowell, Margo McKnight, Anne Meylan, Peter Meylan, Jerry Reynolds, Alan Savitzky, Norman Scott, Larry Settle, Jeffery Tamplin, and Bradford Winn.

SSAR Student Travel Awards Fundraiser Call For Donations

At the 1995 SSAR meetings in Boone, North Carolina, the SSAR Student Travel Awards Committee introduced its second annual Frameable Art Silent Auction to raise funds for students

attending and presenting papers at the 1996 meeting in Lawrence. The outcome of this year's silent auction was especially positive, with over $1700 raised. On behalf of SSAR and the Student Travel Awards Chair, Dawn Wilson, thanks to all who participated. Hoping to continue this successful tradition, the Student Travel Awards Committee is pleased to announce the third annual frameable art silent auction to be held at the 1996 SSAR meeting in Lawrence. Acceptable donations include: photos of your study animal (or herpetologists!), line drawings, prints, paintings, or anything that can be put into a frame, if not framed already. If you are interested in donating an item please contact: *John Lee, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA; tel. 803-725-5873; e-mail: LEE@SREL.EDU.*

HR Miscellany

Effective immediately, *Herpetological Review* will publish e-mail addresses for authors of articles and notes. Authors are requested to include an e-mail address, if available, along with their postal address on all material submitted for publication in *HR*.

We have a continuing need for herpetological art work for publication in *HR*. Original drawings should be of a scale that would permit reduction to approximately 30 x 90 mm or smaller. Of particular interest are drawings of material for which locality data or museum catalogue numbers are available; this information should be included with the drawings. Original art (or good quality copies) should be packaged to ensure safe delivery and sent to the Editor (address on inside front cover).

NEWSNOTES

Southwestern Research Station Positions And Grants For 1996

VOLUNTEERS—Approximately 20 volunteer positions are open in 1996 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax 520-558-2396.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. Application due date: February 15, 1996. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; tel. and fax 520-558-2396.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reservations, answering phones, greeting guests, supervising volunteers, etc. Begin March 15, 1996, through September 1996. Five-day week; salary $190/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. Tel. and fax: 520-558-2396.*

Graduate and Post-Graduate Research Grants

The Biological Research Station of the Edmund Niles Huyck Preserve offers grants (max. = $2500) to support biological research which utilizes the resources of the Preserve. Among the research area supported are basic and applied ecology, animal behavior, systematics, evolution, and conservation. The 2000 acre Preserve is located on the Helderberg Plateau, 30 miles southwest of Albany, New York. Habitats include northeast hardwood-hemlock forests, conifer plantations, old fields, permanent and intermittent streams, 10 and 100 acre lakes, and several waterfalls. Facilities include a wet and dry lab, library, and houses/cabins for researchers. Deadline = 1 February 1996. Application material: *Dr. Richard L. Wyman, Executive Director, E.N. Huyck Preserve and Biological Research Station, P.O. Box 189, Rensselaerville, New York 12147, USA.*

Reptilia

A new bimonthly magazine devoted to reptiles and amphibians is being published. *Reptilia* is the only herp magazine published in Spanish for herpetoculturists.

The main objectives of *Reptilia* are to spread information about the diverse aspects involved in keeping terrarium animals; to report on their natural history and thus facilitate the understanding of their needs; to encourage breeding; to give credible and easily understood veterinary information to amateurs and professionals alike; to offer information about legislation and regulation; to demythologize the world of these animals through knowledge of their relationship to different cultures; and to serve as a medium through which all interested parties can communicate. For more information contact: *Reptilia*, c/ Muntaner 88, 5° 1ª, 08011 Barcelona, Spain. Fax (93) 280 64 94.

International Hylid Society

The International Hylid Society is a new organization dedicated to treefrog enthusiasts worldwide. Membership is open to anyone with an interest in treefrogs. This includes anyone from the pet-keeper to the professional herpetologist. The focus of the organization is on treefrogs—not just those of the family Hylidae—but any of the many "treefrog" species throughout the world. This is a non-profit organization that serves as a resource and information exchange center to benefit the members and the well being of the treefrog species they keep or study.

Members will receive *The Bulletin of the International Hylid Society* on a quarterly basis. This will contain articles on a variety of topics such as species profiles, husbandry techniques, breeding information, vivarium construction, insect culturing methods, up-to-date information from several zoos, hard-to-find international articles, various tips and ideas on a variety of subjects. The *Bulletin* will also include classified ads (free to members), a breeder directory, and full color photos.

Volume 1 Number 1 will be published Jan/Feb 1996. We are currently accepting article and photograph submissions. Classified ads are also being accepted. Membership is US $15.00 per year. If you would like your name to appear in the breeder directory along with the species you work with, please include the scientific name(s) of those species. This directory will be made available to members only. Please make check or money order payable in U.S. funds to: The International Hylid Society, and send it with your postal information to: *William Brown, c/o Amphibian Conservation and Research Center, 1423 Alabama St., Lafayette, Indiana 47905, USA. Tel. (317) 742-5331; e-mail 102436.2415@compuserve.com*

LEGISLATION & CONSERVATION

Call for information on the status of amphibians and reptiles. This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information especially on the State and Province level. Please send pertinent information to the Section Editor.

USA: The U.S. Fish and Wildlife Service is seeking public comments on a proposal to list the frog guajõn (*Eleutherodactylus cooki*) as threatened on the the Federal list of threatened and endangered species. This frog is found only on the island of Puerto Rico, where it is known only from the Pandura Mountain range in the extreme southeastern part of the island. No critical habitat will be proposed for the species. Comments should be submitted to the Supervisor, U.S. Fish and Wildlife Service, Caribbean Field Office, P.O. Box 491, Boqueron, Puerto Rico 00622, USA. *(Information summarized from a USFWS News Release, dated 2 October 1995).*

USA: U.S. Fish and Wildlife Service: The Director of the USFWS signed a new "Policy on Candidate Assessment and Petition Management Under the Endangered Species Act" (19 July 1995). This policy changes the Service's designation of candidates for listing pursuant to the Act. As of 19 July, the term "candidate" means only those species for which the Service has sufficient information indicating that listing may be appropriate (i.e., species that were previously known as category 1 candidates). Species formerly known as category 2 candidates will now be referred to as "species at risk." *(Information summarized by Cindy Schultz, USFWS).*

USA: The U.S. Fish and Wildlife Service was petitioned on 23 May 1995 by the Environmental Protection and Information Center of Garberville, California, and ten co-petitioners including the Sierra Club and the California Sportfishing Alliance, to list the southern torrent (formerly Olympic) salamander (*Rhyacotriton variegatus*), as threatened. On 29 June 1995, USFWS published a "90 day finding" in the Federal Register stating that the petition has merit, thus initiating a one year status review period in which to gather additional information. The southern torrent salamander resides in headwater habitats of conifer-dominated, usually mature and old-growth forests from north central Oregon to northwestern California. This salamander is patchily distributed and is found along cold, clear, highly oxygenated waters. Adults have low fecundity and low vagility; larval metamorphosis requires 4–5 years. These natural history attributes make this species highly susceptible to perturbations which increase sedimentation and raise water temperatures. Comments and concerns should be addressed to: Ann Chrisney, USFWS, 2800 Cottage Way, Room E-1803, Sacramento, California 95225-1846, USA. *(Information provided by Hart Welsh, Redwood Sciences Laboratory, 1700 Bayview Drive, Arcata, California 95521, USA).*

CITES: The U.S. Fish and Wildlife Service approved the export from the U.S. of American alligators (*Alligator mississippiensis*) harvested during 1995–1997 harvest seasons from certain states previously approved for such export for the 1992–1994 seasons (AL, FL, GA, LA, MS, SC, TX) and Arkansas, which was previously approved for the 1994 harvest season. The approval stipulates that monitoring procedures previously established be continued and states the manner in which tags are to be attached to the hides at the time of export and the conditions for export of parts and products. *(Federal Register, 21 August 1995).*

USA: U.S. Fish and Wildlife Service: The USFWS has received a petition for a rule to list southern California populations of the mountain yellow-legged frog (*Rana muscosa*) under the Endangered Species Act. The petitioners state that the best current scientific evidence indicates that the southern populations of this frog constitute a distinct taxonomic unit separate from frog populations inhabiting the Sierra Nevada mountain range. The petition was submitted on 10 July 1995 and places response requirements on the USFWS. For more information contact: *Biodiversity Legal Foundation, P.O. Box 18327, Boulder, Colorado 80308-1327, USA.*

USA: Alabama: Alabama has initiated a Herpetological Atlas project and is looking for participants. The goal is to have as many volunteers in as many areas of the state as possible. For further details on how to get involved contact: *Alabama Natural Heritage Program, P.O. Box 301455, Montgomery, Alabama 36130-1455, USA. Tel. (334) 242-3033.*

A New Book from the Society for the Study of Amphibians and Reptiles

Contributions to *West Indian Herpetology*

A volume edited by ROBERT POWELL *and* ROBERT W. HENDERSON

With a foreword by
THOMAS W. SCHOENER

THIS NEW BOOK (with contributions by 59 authors from the United States, Europe, and the West Indies) provides an introduction to Antillean herpetology, including a history of West Indian herpetology, an updated checklist of the herpetofauna (including full literature citations for the original descriptions of all 622 species), and a section of **COLOR PLATES** illustrating representatives of all genera of native West Indian amphibians and reptiles. Also included are papers providing a broad view of current herpetological research in the West Indies (with a strong emphasis on field-oriented projects). All research chapters are abstracted in English, Spanish, and French.

Specifications: 460 pages, 31 black-and-white photographs, numerous figures, 8 color plates (71 photographs), index to scientific names. Format 8 ½ × 11 inches (21.5 × 28 cm). Clothbound. To be issued March 1996. ISBN 0–916984–37–0.

Prices: SSAR members *before publication* . . . . US$40 • Institutions and Non-members $60
Shipping: In USA, add $2; non-USA, add $4.

Send orders to: Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103, USA (*Telephone*: area code 314, 977–3910 or –3916; *fax*: 314, 977–3658; *e-mail*: SSAR@sluvca.slu.edu). Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks (include an additional amount to cover bank conversion charges) or by International Money Order. All persons may charge orders to MasterCard or VISA (please provide account number and expiration date). Details concerning membership in SSAR and a complete list of Society publications can be obtained on request to Dr. Aldridge.

MEETINGS

Meetings Calendar

12–14 April 1996—Minton Symposium, Indiana Academy of Sciences, Indiana University/Purdue University Conference Center, Indianapolis, Indiana, USA. *Refer to meeting announcement in this issue for details.*

Mid-April 1996—2nd International Conference on the Biology and Conservation of the South Asian Amphibians and Reptiles, University of Peradeniya. Contact: Anslem de Silva, Conference Director, Faculty of Medicine, University of Peradeniya, Sri Lanka. Tel. 94-08-88130. Fax 94-08-32572.

13–19 June 1996—76th Annual Meeting, American Society of Ichthyologists and Herpetologists, together with the 44th Annual Meeting of The Herpetologists' League, New Orleans, Louisiana, USA. Hosted by the University of New Orleans. Deadline for receipt of abstracts 1 April 1996. Contact: Dr. Bob Cashner, ASIH Local Committee Chair, Dept. Biological Sciences, University of New Orleans, New Orleans, Louisiana 70148, USA. Tel. (504) 286-6741; fax (504) 286-6121; E-mail RCCBS@UNO.EDU

24–29 July 1996—39th Annual Meeting, Society for the Study of Amphibians and Reptiles. Hosted by The University of Kansas, Lawrence, Kansas, USA. *Refer to meeting announcement in this issue for details.*

20–24 August 1996—2nd International Symposium and World Congress on the Preservation and Conservation of Natural Science Collections: "Natural Science Collections—A Resource for the Future." To be held at St. John's College, Cambridge, U.K. Contact: Chris Collins, Natural Sciences Congress '96, Geological Conservation Unit, Department of Earth Sciences, Downing Street, Cambridge, CB 2 3EQ, United Kingdrom. Tel. (0223) 62522; fax (0223) 60779.

British Herpetological Society Meetings for 1996

The British Herpetological Society has released a preliminary timetable for meetings during 1996. Further details concerning time and venue for most of these meetings will be published in the BHS *Bulletin* as soon as they become available. Additional information concerning meetings or membership may be obtained by correponding with: *The Secretary, British Herpetological Society, c/o Zoological Society of London, Regent's Park, London NW1 4RY, U.K.*

1. Herpetofauna Recorders Meeting (HRM) (early February; Edinburgh probable site).
2. Annual General Meeting, Birkbeck College, London (23 March). Speakers include Dr. Susan Evans: "Origin, evolution and diversification of lizards;" Colin Fitzsimmons: "The role of the BHS Education Officer."
3. London Zoo Day (30 March).
4. Conservation & Education Event, Jersey Zoo (4–5 May).
5. Visit to Beam Brook (mid-May).
6. Captive Breeding Meeting (i) (25 May).
7. Captive Breeding Meeting (ii) (20 July).
8. Captive Breeding Meeting (iii) (12 October).
9. Autumn General Meeting, Birkbeck College, London (26 October). Speakers include Prof. J. Davenport: "Intertidal Madeiran lizards—miniature marine iguanas;" Dr. M.R.K. Lambert: "Herpetofauna as bioindicators to assess environmental impact of a pesticide spill in Somaliland."
10. Captive Breeding Open Day, New Denham (9 November).
11. Research Meeting, Birkbeck College, London (7 December).

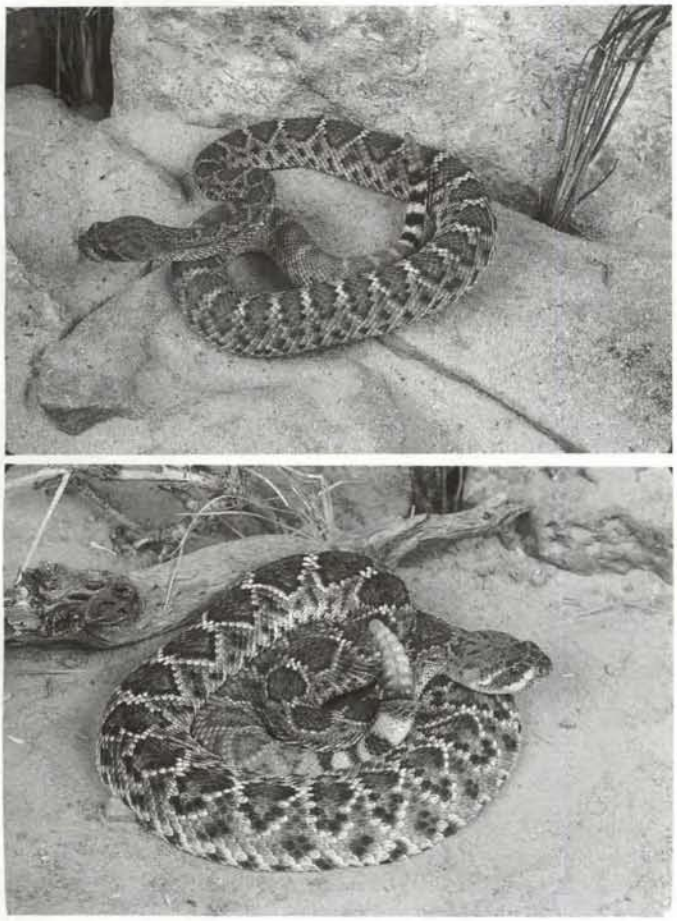
New York Turtle & Tortoise Society Meetings

The New York Turtle & Tortoise Society has established the following meeting schedule for early 1996: 21 January, 18 February, 17 March, and 21 April. Meetings are held at the American Museum of Natural History (Room 319) in New York. For further information contact: NYTTS, P.O. Box 878, Orange, New York 07051, USA. Tel. (212) 459-4803; E-mail asalzberg@aol.com

SYMPOSIUM IN HONOR OF DR. SHERMAN A. MINTON, JR.
12–14 April 1996, Indianapolis, Indiana

The Indiana Academy of Sciences is sponsoring a Symposium in April of 1996 in honor of **Sherman A. Minton, Jr**. on the occasion of the publication of his revision of the *Amphibians and Reptiles of Indiana*. The symposium will be held 12–14 April 1996 in Indianapolis at the Indiana University/Purdue University Conference Center. Dr. Minton is well known for his work on venomous reptiles, the reptiles of Pakistan, the regional herpetology of the midwest, and popular books on herpetology.

The Symposium will include a Friday evening (12 April) dinner featuring **Whit Gibbons** as the after dinner speaker. The morning program of the Saturday Conference (13 April) will focus on the career of Dr. Minton with talks by **Carl Gans** (Minton's work on the reptiles of Pakistan), **David Hardy** (pitviper bites), **Bernard Bechtel** (abnormalities in reptiles), and **Harold Voris** (venomous sea snakes). The afternoon session will focus on "Hoosier Herpetology" and the publication of Minton's revision of his classic monograph on the herpetofauna of Indiana; biologists working on the amphibians and reptiles of Indiana will present brief overviews of their research and provide a perspective on herpetological research in Indiana today. On Sunday (14 April) there will be optional field trips.

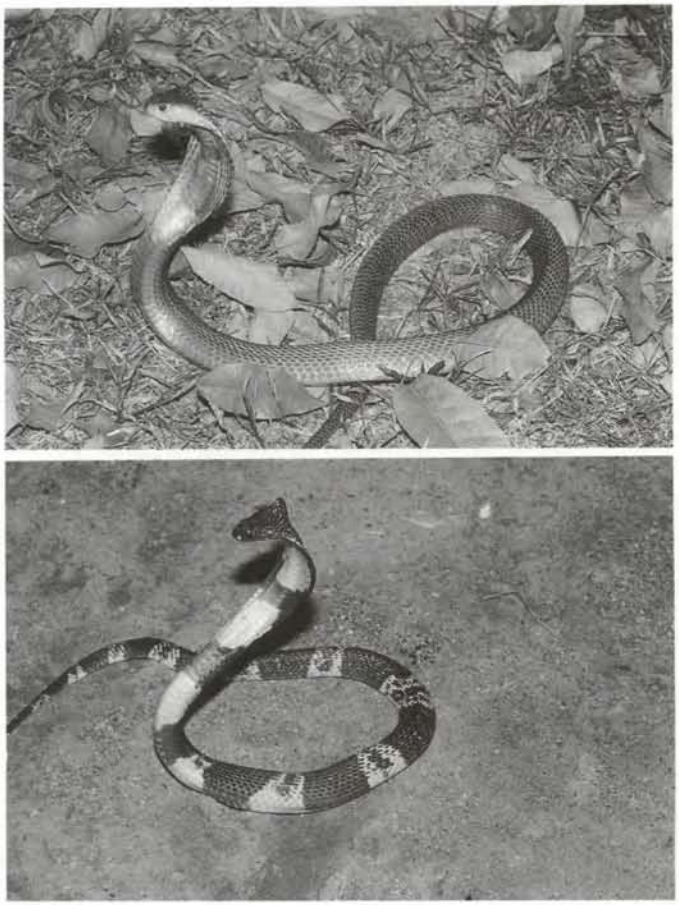


For registration information, contact: Harriet A. Rodenberg (Minton Conference), University Place, Conference Center and Hotel, 850 West Michigan Street, Indianapolis, Indiana 46202-5198, USA. Tel. 317-274-5053; Fax: 317-274-3878; e-mail: hrodenbe@indycms.iupui.edu

CURRENT RESEARCH

The purpose of **Current Research** is to present basic summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA; e-mail: breckbarth@aol.com. Comments and suggestions are also welcome.

Snake Systematics and Evolution



Using three different types of taxonomic characters, Murphy et al. examined the rattlesnakes *Crotalus ruber* and *C. exsul*. The two species differed by a single nucleotide in the 297 base cytochrome *b* gene sequenced and in the allelic frequency of one (of 29) allozymes. The authors recommend the two species be considered a single species, *C. exsul*, consisting of three subspecies, *C. e. exsul, C. e. ruber,* and *C. e. lorenzoensis*, the latter being restricted to the Isla San Lorenzo Sur population.

One species or two? Top: *Crotalus exsul* (México: Baja California: Isla Cedros). Bottom: *Crotalus ruber* (México: Baja California: Bahía de los Angeles). Photos by Louis Porras.

MURPHY, R. W., V. KOVAC, O. HADDRATH, G. S. ALLEN, A. FISHBEIN, AND N. E. MANDRAK. 1995. mtDNA gene sequence, allozyme, and morphological uniformity among red diamond rattlesnakes, *Crotalus ruber* and *Crotalus exsul*. Can. J. Zool. 73:270–281.

By sequencing the cytochrome oxidase I (COI) region of the mtDNA, Wüster and Thorpe found a cryptic species of Asiatic spitting cobra, *Naja siamensis*. This cryptic species is an important cause of snakebite in Thailand and the authors urge comparisons of venom composition and antivenin between this species and *Naja kaouthia* to ensure optimal snakebite treatment.

Naja siamensis, a newly described species of Asiatic spitting cobra, occurs in two color phases. Top: Uniformly brown morph from Khok Samrong District, Lop Buri Province, Thailand. Bottom: Black-and-white morph from Ta Khli District, Nakhon Sawan Province, Thailand. Despite these stunning color differences, the authors found no differences in cyctochrome oxidase subunit I sequence. Photos by Wolfgang Wüster.

In another paper, Wüster et al. compare morphology and mtDNA sequences to determine the population systematics of Asiatic cobras. The distribution of four *Naja* species are mapped and many problematic populations are resolved. The usefulness of the COI region of mtDNA is discussed.

WÜSTER, W., AND R. S. THORPE. 1994. *Naja siamensis*, a cryptic species of venomous snake revealed by mtDNA sequencing. Experientia 50:75–79.

WÜSTER, W., R. S. THORPE, M. J. COX, P. JINTAKUNE, AND J. NABHITABHATA. 1995. Population systematics of the snake genus *Naja* (Reptilia: Serpentes: Elapidae) in Indochina: Multivariate morphometrics and comparative mitochondrial DNA sequencing (cytochrome oxidase I). J. Evol. Biol. 8:493–510.

A new snake genus, *Xenophidion*, as well as two new species were recently described by Günther and Manthey. *Xenophidion* is regarded as a distinct evolutionary lineage, presumably of the Colubridae. It is distinguished from all other snakes by "the position and shape of the palatine process and with it the anterior connection between the maxilla and palatine, the broad and long

ectopterygoid process of the maxilla, the form of the anterior dentary with an enlarged caniniform tooth, as well as the pholidosis on the head." The authors plan to compare *Xenophidion* to snakes representing all existing families and subfamilies to determine its systematic position.

GÜNTHER, R., AND U. MANTHEY. 1995. *Xenophidion*, a new genus with two new species of snakes from Malaysia (Serpentes, Colubridae). Amphibia-Reptilia 16(3):229–240.

Jackson and Fritts examined tooth surface morphology of several colubrid and elapid snakes to determine the origin of the proteroglyph fang. The authors propose that ridges on the posterior maxillary teeth have rotated to form a hollow fang in opisthoglyphous snakes. The morphology of opisthoglyph and proteroglyph fangs appears to be homologous, suggesting a posterior maxillary origin for the proteroglyph fang.

JACKSON, K., AND T. H. FRITTS. 1995. Evidence from tooth surface morphology for a posterior maxillary origin of the proteroglyph fang. Amphibia-Reptilia 16(3):273–288.

North American Tortoises

The effect of precipitation, average maximum temperature, and average minimum temperatures on the growth rate of the four species of North American tortoises was examined in a recent paper by Germano. His preliminary analysis suggests that these environmental factors are not the main determinants of growth in tortoises. In addition, growth rates were used to determine the mean age at maturity for each of the four species.

GERMANO, D. J. 1994. Growth and age at maturity of North American tortoises in relation to regional climates. Can. J. Zool. 72:918–931.

Unpublished reports state the desert tortoise, *Gopherus* (=*Xerobates*) *agassizii*, has experienced dramatic declines during the last 100 years. These reports were important to the U.S. Fish and Wildlife Service decision to list *G. agassizii* as threatened. In reviewing the data in these reports, and additional information, Bury and Corn failed to find any evidence of the presumed dense, wide-spread historical populations. Using this example the authors stress the use of peer-reviewed data in formulating management decisions.

BURY, R. B., AND P. S. CORN. 1995. Have desert tortoises undergone a long-term decline in abundance? Wildl. Soc. Bull. 23(1):41–47.

Amphibian Systematics and Evolution

Riehl and colleagues used micro-complement fixation (MC'F) to clarify the relationships among some Palearctic hylid frogs of the genus *Hyla*. The groups distinguished by MC'F are consistent with patterns of speciation that can be supported by biogeographical history.

RIEHL, C. J., J. T. LELL, AND L. R. MAXSON. 1995. Relationships among Palearctic *Hyla*: Insights from immunology. Biochem. Syst. Ecol. 23(3):245–249.

DNA sequences of the conservative 12S and 16S ribosomal RNA genes were used to develop a phylogeny for amphibian higher classification. The monophyly of the three amphibian orders and two anuran suborders (Neobatrachia and Archaeobatrachia) are supported by the data. Relationships between familes are also discussed, although within Caudata, family relationships are not resolved at significant confidence levels.

HAY, J. M., I. RUVINSKY, S. B. HEDGES, AND L. R. MAXSON. 1995. Phylogenetic relationships of amphibian families from DNA sequences of mitochondrial 12S and 16S ribosomal RNA genes. Mol. Biol. Evol. 12(5):928–937.

Phylogenetic relationships within the salamander family Salamandridae were examined using both DNA sequences and morphology. The two data sets were highly congruent. Monophyly of the family is supported, however some of the genera within the family are found to be paraphyletic.

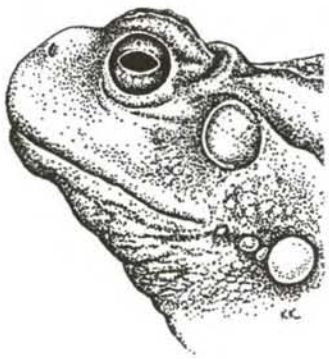
TITUS, T. A., AND A. LARSON. 1995. A molecular phylogenetic perspective on the evolutionary radiation of the salamander family Salamandridae. Syst. Biol. 44(2):125–151.

Amphibian Parasites

Vojtkova and Roca review the trematode parasites found in European anurans. They found that 49 species of adult Digenea and 39 species of larvae have been recorded from 16 species of anurans. These data are presented in several tables, and are divided by the parasites recorded for each species of anuran, geographic distribution, as well are the organ parasitized. An important list of references is also provided.

VOJTKOVA, L., AND V. ROCA. 1994. Parasites of the frogs and toads in Europe. Part II: Trematoda. Rev. Esp. Herp. 8:7–18.

Drought Ecology



Germano et al. discuss the effect of a one-year drought on the behavior and reproduction of a population of *Gambelia sila*. During the drought adults were not found above ground and did not breed. Yearling lizards, however, were found above ground. The authors consider three hypotheses to account for the response of these iteroparous lizards to drought.

GERMANO, D. J., D. F. WILLIAMS, AND W. TORDOFF III. 1994. Effect of drought on blunt-nosed leopard lizards (*Gambelia sila*). Northwest. Nat. 75:11–19.

Quantitative Genetics

The heritability of locomotor speed and endurance were determined for a population of the lizard *Lacerta vivipara*. Heritability was low for speed but high for endurance and the authors found no evidence for a trade-off between the two characters. The authors discuss their data with respect to the hypothesis of a genetic trade-off between speed and endurance.

SORCI, G., J. G. SWALLOW, T. GARLAND, AND J. CLOBERT. 1995. Quantitative genetics of locomotor speed and endurance in the lizard *Lacerta vivipara*. Physiol. Zool. 68(4):698–720.

announcement ***a paid non-political advertisement*** **announcement**

Bill Lamar and George Gorman's

GREEN TRACKS
ECO-TOURISM WITH A HERPETOLOGICAL TWIST

Amazonia Costa Rica Ecuador South Africa

'VANTED!! Herpetologists looking for exciting busman's holidays!
University Groups Extension Classes

Green Tracks is unique among ecotour companies in being owned and operated by herpetologists.

Bill Lamar is the co-author of the well known Campbell/Lamar monograph :
The Venomous Reptiles of Latin America

He has years of field experience in Amazonia, dating back to the early '70's when he began working with Federico Medem. He's a great field naturalist- a typical one week Green Tracks Tour out of Iquitos will lead to over 100 identified species of herps.

George Gorman has recently joined with Bill as co-owner. George was a Professor of Biology at UCLA who has worked extensively in the West Indies and other island groups. He also went to law school, but we don't tell anyone.

We have regular departures from Miami to Iquitos, Peru for Amazonian Boat expeditions; plus trips to Ecuador, Costa Rica and elsewhere. Currently planning a South African herpetotour for August '96 in conjunction with Bill Branch .

Of course, we would welcome readers of *Herpetological Review* to join us on a trip -

but the main motivation for this announcement is
to get you to think about how your institution might work with us

Extension courses; Field biology semesters; Tropical Ecology

Green Tracks has led custom trips for the Vancouver Aquarium, the Denver Zoo, National Geographic etc. We offer great natural history tours in a relaxed and friendly atmosphere.

Contact us and let's work on a customized tour.
for a list of upcoming trips call 1-800-9Monkey
fax 510 527 7087 email paganda@ix.netcom.com
Greentracks P.O. Box 9516 Berkeley California 94709

LETTER TO THE EDITOR

The Last Word

The response to my cladistics article, both in volume of published pages and in prestige and scholarly standing of respondents, was heartening. I am particularly pleased that Peter Meylan instigated discussions of my paper with Henry Mushinsky's herpetology discussion group at USF, and delighted to hear also from Wayne King that the paper had been circulated to participants in the UF herpetology course for review and discussion. My purpose was to stimulate thought by providing an unequivocal counterpoint to cladistic dogma, and I could not have asked for a more gratifying response, even though the four responses included few words of praise. I take heart from the fact that, of the many dozens of specific points and criticisms I raised, only isolated ones were selected for response. But whether the many unchallenged points are indeed unanswerable is for others to judge.

Reading the responses and pondering their messages, I actually find less fundamental disagreement than might be anticipated. Dr. Kluge selected a defense of the principle of parsimony as his theme, although I wish he had been less theoretical and instead had given some concrete examples. I remain convinced that an unbiased cladist might indeed place Galapagos and Aldabra tortoises in a single clade. But the truth is that I obviously do not reject commonsense use of parsimony or identification of shared derived features, nor does Dr. Kluge portray these as paths to absolute truth. We just lie at different points on a continuum. Where our philosophies diverge is as follows: I concede that any and all approaches to systematics use a form of commonsense cladism, by identification of obvious synapomorphies. The African and Indian elephants, although generically distinct, obviously form a clade separate from other extant taxa (although including numerous extinct forms), and it doesn't take a computer analysis to conclude that large ears, tusks, trunk, giant size, etc. are, in this case, indicative of genuine relationship. I also acknowledge that "commonsense" conclusions based upon morphology can be disturbed or even reversed by genetic or molecular data. Kluge's thesis is that far more refined taxonomic conclusions (or hypotheses) can be made by consideration of more and finer-grained characters and by subjecting the data gathered to computer analysis. My conclusion, by contrast, is that there is a point where common sense and "gestalt cladism" ends, and that this is where one should stop. Too many events—ranging from uncertain character polarity, to dubious sister-group selection, to excessive reliance upon the principle of parsimony to choose between ambiguous scenarios, to arbitrary or subjective character selection, to the phenomenon of parallel adaptive modifications in unrelated organisms generating, not one, but a suite of false shared derived characters—can intervene to make the more rarified extremes of cladism unlikely to show convergence with actual past events. Adherents claim that their hypotheses are testable, but this is not strictly true—an absolute test would require that the existence of "node" forms in the fossil record, and the characters that distinguish them, would be predicted and then confirmed by actual discovery. If, on the other hand, "nodes" have no real existence, past or present, and cladists do not even seek them, as Meylan has argued, then I suggest that they have no place in science.

I found Darrel Frost's comments, that might be paraphrased "The man is DANGEROUS! He has a FOLLOWING! He must be STOPPED!" somewhat ad hominem in nature. Obviously I am happy that people read my stuff. Moreover, to disparage turtle hobbyists is unwise and unjust. The most dedicated ones provide an important counterpoint to theoretical systematists, in that they actually handle large numbers of specimens—living ones at that—of species that may be very poorly represented in museums, and they develop an "eye" for shades of regional variation—or even new species—that often elude those dependent upon available museum series. Indeed, the majority of new turtle taxa described in the last decade were discovered by hobbyists. Moreover, hobbyists' taxes help pay for publicly-funded turtle research, and this, I believe, gives researchers with government grants an obligation to make their findings comprehensible to an educated lay audience.

But all good debates must come to an end, and the time comes when one must call for a vote. I start from behind—four resounding "nay" votes were received by *Herp. Review*. But these must be weighed against fourteen written responses (I exclude numerous verbal messages of support) that reached me directly—and not from hobbyists, but in all cases from professional herpetologists and evolutionary biologists, all with instant name-recognition and standing within the professional community. Excerpts from some of these letters, all of which were supportive, are as follows:

"This is the most heartening discourse I've ever read on the subject of cladistics, although you go where angels fear to tread. It is an expository gem, intelligible throughout (what a rarity in this subject's literature), thorough in treatment, disarmingly documented—a scholarly masterpiece."

"Just a note to thank you for the wonderful article you obviously took great pains to prepare.... I had felt like a 19th century naturalist, isolated from scientific respectability with a tiny number of others, until I read your piece."

"I've just read your article on cladism..., and found myself actually laughing aloud—sympathetically—while reading a professional contribution. I heartily agree with your feelings, which you are certainly at pains not to disguise, and with your points, which are well made indeed."

"Very much enjoyed your unClad attack.... Said things I always wanted to say, but didn't have the background. Good show!"

"I don't know how long it has been since I enjoyed a scientific paper as much as I did your Cladism: The Great Delusion."

"Thanks for the thoroughly enjoyable paper. This was salve for my soul, after so many confrontations with the cladistic police. Count me among the reactionary forces of numerical taxonomy downtrodden but sure to rise again.... Thanks for the breath of fresh air.... It is true that there has been a revolution in systematics, resulting in many new journals, many exciting conclusions, and a lot of stimulating debate. But this revolution isn't cladistics. Molecular systematics is a genuine 'new way of seeing,' and cladistic methodologies have not fared well in this arena."

"Your recent article on cladism is passionate, reasoned and illuminating. I believe the voices of dissent are getting louder.... I suspect that cladism will never really disappear because it promises something that the new generation so badly desires—the promise of instant gratification and with it the bonus of innumerable opportunities to christen new names for old taxa."

"The title of your article—the great delusion—could be taken one step further. Cladists now assign polarities to characters. These characters are then used to override their own computer pronouncements. The cladists are, therefore, no more than traditional morphologists in computer clothing. The problems your article raised about confusing opinion with fact need no more expansion to you."

"We will overcome someday."

Gentlemen (for no ladies voted)—it seems the ayes have it.

ARTICLES

Age at Maturation, Body Size, and Life-History Evolution in the Salamander Family Plethodontidae

Tilley and Bernardo (1993) have done herpetologists a great service in their review of life history evolution in the salamander family Plethodontidae. They are quite correct in their interpretation that our current understanding of plethodontid life history evolution is based more on traditional viewpoints (e.g., Dunn 1926) than on real data. My intent in this paper is to supplement their suggestions on research directions in this family of salamanders.

What are the Important Aspects of Plethodontid Life Histories?

Because body size affects nearly every aspect of plethodontid evolutionary ecology (e.g., Hairston 1987; Tilley and Bernardo 1993), I will focus on this key trait. I will argue that the primary influences on interspecific and intraspecific variation in body size are duration of the larval period and juvenile period.

My arguments require several assumptions. First, while there are good reasons not to ignore the effects of egg size (e.g., Bernardo 1991a, 1994), I do so only to simplify my arguments. Second, I assume that growth after maturation contributes negligibly to interspecific variation in adult body size. At least for females, a significant component of energy formerly dedicated to growth is allocated to reproduction after maturity is attained (Hom 1988; Tilley 1980). This assumption may have less validity for males (Bruce 1993; Tilley 1980).

Egg size effects aside, there are only four ways to change body size in an amphibian: change (1) larval growth rate; (2) juvenile growth rate; (3) duration of the larval period; and (4) duration of the juvenile period. I will argue that variation in plethodontid life histories is due primarily to the latter two, and variation in growth rate contributes negligibly to variation in life histories.

For example, *Desmognathus monticola* attain a larger body size as adults than do *D. ochrophaeus* (Organ 1961). They do so primarily by extending the length of the juvenile period; growth rate and egg size play less important roles (Bruce 1990). The result is an additional year of growth prior to maturity, with all the correlated effects, e.g., increased clutch size and egg size (Bernardo 1994; Tilley 1968). Extending the comparison to the largest species in the genus, *D. quadramaculatus*, the larger size of this species seems to be due to an increase in larval period, relative to *D. monticola* and *D. ochrophaeus* (Bruce 1988a).

Changing the duration of the larval or juvenile period can also explain intraspecific variation in adult body size. Tilley (1973) specifically ascribed large body size of high elevation *D. ochrophaeus* (relative to low elevation conspecifics) to delayed maturity. The growth curves of Tilley (1980) document that the larger size of high elevation individuals is due to an additional year of growth as juveniles, with variation in growth rate contributing little to the difference in adult body size. In an elegant study, Bernardo (1994) convincingly demonstrated that this life history variation is due to genetic difference in maturation age and that growth potential does not differ between these populations.

In order to determine whether this trend is a general one for the desmognathines, I used the data that Tilley and Bernardo provided (their Table 1) to calculate approximate growth rates and evaluate the degree of interspecific variation in this trait (these rates should not be regarded as estimates of growth rate in natural populations). These rates are presented in Table 1.

As a test of the utility of these estimates, I constructed a table that listed the contributions of hatching size, growth rates, and age at maturation to the difference in adult body size between *D. monticola* and southern *D. ochrophaeus*. This table was compared with that listed in Bruce (1990)—who used real animals—and the differences between my estimates and Bruce's appeared to be small enough (Table 2) to allow interpretation of growth rate data of Table 1. (Because Tilley and Bernardo's table used Bruce [1990], I removed any data attributable to this reference so that the estimates presented in Table 2 were as independent as possible. Thus, in constructing Tables 1 and 2, I used Juterbock [1984] as my primary reference for *D. monticola*. However, the only estimate of minimum age at maturity for this species is found in Bruce [1990]. Thus the two data sets present in Table 2 are not completely independent.)

TABLE 1. Rates of growth estimated from Tilley and Bernardo (1993). Larval growth rate is calculated as

$$\frac{\text{(size at metamorphosis} - \text{hatching size)}}{\text{(age at metamorphosis)}}.$$

Juvenile growth rate is calculated as

$$\frac{\text{(size at maturity} - \text{size at metamorphosis)}}{\text{(age at maturity} - \text{age at metamorphosis)}}.$$

Data are medians taken from Tilley and Bernardo. *Desmogathus aeneus* and *D. wrighti* are direct-developers (Collazo and Marks 1989; Harrison 1967; Organ 1961; Wake 1966).

Species	larval growth rate (mm SVL/mo)	juvenile growth rate (mm SVL/mo)
Desmognathus quadramaculatus	0.62	0.67
Leurognathus marmoratus	0.59	1.08
Desmognathus monticola	0.30	0.80
Desmognathus fuscus (northern)	0.63	1.17
Desmognathus ochrophaeus (southern)	0.40	0.54
Desmognathus aeneus	—	0.48
Desmognathus wrighti	—	0.40

The growth rates do not differ dramatically across taxa in the way one would expect if variation in growth rate is a significant component of interspecific variation in body size (Table 1). In addition, I used the growth rates present in Table 1, and the data on minimum SVL at maturity and minimum age at maturity from Tilley and Bernardo, to generate Pearson correlation coefficients among these traits. Larval growth rate was not correlated with SVL at maturity ($r = 0.36$, df = 3, $P > 0.05$); nor was juvenile growth rate ($r = 0.59$, df = 5, $P > 0.05$). However, age at maturity was positively correlated with SVL at maturity ($r = 0.77$. df = 5, $P < 0.05$). Thus, it appears that variation in body size in desmognathine salamanders is most related to variation in maturation age. Maturation age is simply a function of the duration of the larval and juvenile periods.

Does this pattern hold for the other groups of the plethodontids, i.e., the tribes Plethodontini, Bolitoglossini, and Hemidactyliini of the subfamily Plethodontinae? As noted by Tilley and Bernardo, there is little information concerning life histories in the

Plethodontini and Bolitoglossini, but dramatic variation in several species of the Hemidactyliini has been well documented and suggests that the trend for the desmognathines also holds for the hemidactyliines.

For example, the hemidactyline *Gyrinophilus porphyriticus* in the southern Appalachians exhibits variation in age at maturation. In the Cowee, Nantahala, Balsam, and southern Blue Ridge Mountains, the larval period is 3–5 yr (Bruce 1980). In the Nantahala and Balsam Mountains and Cowee Mountains northwest of Watauga Gap, *G. porphyriticus* individuals follow metamorphosis with a one year juvenile period, whereas those from the southeast Cowee Mountains and southern Blue Ridge Mountains are mature at metamorphosis (Bruce 1972, 1978). The result of this accelerated maturation is smaller animals. Further, *G. porphyriticus* from the Great Smoky Mountains metamorphose at a small size (suggestive of a short larval period) but mature at a size comparable to the Northwest Cowee, Nantahala, and Balsam Mountain populations, suggesting an extended juvenile period (Bruce, unpubl. data). This indicates that geographic differences in adult body size in *G. porphyriticus* are due to variation in larval period and juvenile period.

Thus, a key question for researchers involves the relationship between larval period and juvenile period. A relationship usually exists between age at metamorphosis and age at maturation. However, the correlation is usually a spurious one: paedomorphs notwithstanding, a long larval period is accompanied by a delay in maturation. There may be no correlation between length of the juvenile period and length of the larval period (for the species of Table 1: $r = -0.23$, $df = 5$, $P > 0.05$). While this analysis is based on only a few data, it suggests the hypothesis that age at maturation and age at metamorphosis are free to evolve independently. Previously, Bruce (1989) suggested that the two factors are not tightly linked in desmognathine salamanders. The presence of paedomorphic hemidactyliines further supports this hypothesis.

I suggest that the evolution of body size in plethodontids is largely a result of changes in age at metamorphosis and maturation. I believe that a focus on questions that address variation in larval period and/or juvenile period is most likely to result in informative work. A critical way to address these questions is to generate mortality schedules.

Mortality Schedules and Life History Evolution in Plethodontids

What are the causes of variation in age at maturation in the plethodontid salamanders? All other factors being held equal, life histories evolve when mortality schedules are varied (Charlesworth 1980; Schaffer 1974). For example, Charlesworth (1980) showed that when a delay in reproduction is associated with an increase in fecundity, e.g., via an increase in body size (the case for salamanders [Kaplan and Salthe 1979]), there is selection for delayed maturation when early age mortality is increased. Organ (1961) suggested the hypothesis that the mortality of more aquatic, stream-dwelling plethodontids (i.e., larger species) is higher early in life than in more terrestrial species (i.e., smaller species). If this hypothesis is correct, then high early life mortality can explain delayed maturation and large body size in aquatic plethodontids.

Viewed in this context, the need for clear mortality schedules is outstanding. Currently, there are schedules of survival for only four species of plethodontids: *D. ochrophaeus* (Tilley 1980), *D. fuscus* (Danstedt 1975; Spight 1967), *Plethodon jordani* (Hairston 1983), and *Eurycea wilderae* (Bruce 1988b). Some comparisons can be made among the life tables for these four species. For example, Bruce (1988b) noted that the most aquatic species (*E. wilderae*) has the highest early life mortality and shortest mean generation time, and the most terrestrial species (the direct-developing *P. jordani*) has the lowest early life mortality and longest mean generation time.

TABLE 2. Comparison of two estimates of contributions to difference in adult body size between *Desmognathus monticola* and *D. ochrophaeus*. The estimate from this study is derived from median data taken from Tilley and Bernardo (1993). To facilitate this comparison the juvenile growth rate of *D. monticola* was assumed to be constant.

	Bruce (1990)		This study	
Source of difference	SVL (mm)	%	SVL (mm)	%
Hatchling size	2.4	13.8	3.20	15.6
Age at maturation	11.5	66.1	13.45	65.6
Growth	3.5	20.1	3.85	18.8
Total	17.4	100.0	20.50	100.0

However, more meaningful interpretations will result from life tables of groups of species that are closely related. For example, Organ (1961) provided life tables for five species of desmognathines that suggested that the more aquatic species suffer higher mortality early in life than species that are more terrestrial. However, Organ suggested that all the species he studied matured at the same time, and there is basis for reconsideration of his estimates (e.g., Bruce 1989).

In generating their life tables, these workers assumed that mortality in mature plethodontids is constant. A useful study would be one that tests this assumption, and new techniques for estimating the age of individuals (e.g., osteochrononlogy [Houck and Francillon 1988]) would help in this evaluation.

Age at Maturation and Adaptive Radiation?

While age at maturation is the primary determinant of adult body size in plethodontids, how is it related to other aspects of plethodontid evolution? I suggest that variation in age at maturation is related to, at least, two phenomena that are important aspects of adaptive radiation: speciation and specialization.

Bernardo (1991b) has suggested that because body size influences the distance moved after deposition of a spermatophore (Arnold et al. 1993), divergence in body size between populations can result in sexual isolation. There appears to be significant sexual isolation between the northwest and southeast Cowee Mountain populations of *Gyrinophilus porphyriticus* and this isolation appears to be due to population divergence in body size via differences in age at maturation (Beachy, *in press*). It seems tenable that much of the species diversity of the family is due to evolution of body size and the unique tail-straddle walk of the plethodontids.

Phyletic shifts in body size have been associated with, and may be a cause of, major ontogenetic changes that produce profound new morphologies in amphibians (Hanken 1989). A spectacular example of how change in body size affects morphology, behavior, and ecology is the tropical plethodontid genus *Thorius* (Hanken 1982, 1985).

Researchers often avoid the "tedious" tasks of elucidating life histories and mortality schedules. The work is usually time-consuming and descriptive (problematic for the graduate student looking to make a breakthrough during a time when the power of the

ecological experiment has been fully appreciated [e.g., Hairston 1986; Wilbur 1987]). However, commitment to this descriptive program will provide important insights to plethodontid evolutionary ecology. For at least the Desmognathinae and Hemidactyliinae (the less derived of the four major groups of plethodontids), shifts in maturation age (and sometimes metamorphic age) seem to be the dominant correlate with changes in body size. If changes in body size in plethodontids are due primarily to changes in age at maturity, then the study of life histories is intricately bound with morphology, ecology, and adaptive radiation in, this, the most successful group of caudate amphibians.

Acknowledgments.—I thank S. G. Tilley and J. Bernardo for inspiring this paper with their own, and R. C. Bruce for allowing me to cite unpublished data. This paper was improved substantially by reviews from Bruce and Tilley. My views on plethodontid life histories have been significantly influenced during discussions with Bruce and Bernardo. Impetus for considering life history evolution seriously was provided by J. Neigel. This manuscript was prepared while the author was supported by a Carlos Campbell Memorial Fellowship from the Great Smoky Mountains Conservation Association.

A Second External Character for Distinguishing Garter Snakes (*Thamnophis*) from Water Snakes (*Nerodia*)

In the course of accumulating data on meristic and mensural characters for a book on garter snakes (Rossman et al., *in press*), I was struck by the fact that *Thamnophis validus* appeared to have the scales in the first dorsal scale row (DSR 1) less enlarged (as reflected by the ratio: maximum vertical height of DSR 1/maximum width of vertebral row) than those of its congeners that I had examined up to that point. Since the placement of *validus* in the genus *Thamnophis* is a recent development (de Queiroz and Lawson 1994; Lawson 1987) and runs contrary to the evidence provided by the divided condition of its anal plate—which traditionally had resulted in that species being included in *Nerodia* (Conant 1961)—I surveyed a series of each of the 39 species currently included in the two genera, a total of 641 specimens.

The results of my survey are summarized in Table 1. Not only does *validus* have a less enlarged DSR 1 than all other *Thamnophis* (save for the ribbon snakes, about which more below), but so did all *Nerodia* except female *N. floridana* (one of 13 species exhibiting significant sexual dimorphism in this character—in each case the females have the more greatly enlarged DSR 1).

The data were subjected to one-way ANOVA, and pairwise statistical significance at the 95% confidence limit was determined both by the Fisher PLSD and the Scheffe F-test. Generally, these tests revealed that values at the lower end of the *Thamnophis* range are usually not significantly different from those at the higher end of the *Nerodia* range, although the lack of overlap in the means of these genera (excepting *T. validus*, the ribbon snakes, and female *N. floridana*) certainly seems to be indicative of a trend.

The greatest enlargement of DSR 1 in *Thamnophis* occurs in the highly aquatic *T. gigas* as well as in the terrestrial *T. fulvus*, *T. scalaris*, and *T. scaliger*; the least enlargement in garter snakes (excluding *T. proximus* and *T. sauritus*) is found in the primarily terrestrial *T. marcianus* and *T. radix*. Thus the enlargement of DSR 1 is not obviously correlated with either ecology or behavior, and it may well reflect phylogeny. If this is the case, what are we to make of the failure to conform to their apparent generic mode in the cases of *T. validus*, the ribbon snakes (one of which, *T. sauritus*, has significantly lower values than even the water snakes, a feature noted by Cope 1900), and female *N. floridana*? I confess that the latter baffles me, but the other three species previously had proven to be taxonomically enigmatic, so the evidence from this new character may help to clarify their relationships... or it may serve to further "muddy the water," depending upon one's perspective. In the case of *T. validus*, the possession of a weakly enlarged DSR 1 and a divided anal plate cannot by themselves justify setting aside the taxonomic conclusions based on molecular data; nevertheless, they strongly suggest that the question of whether *validus* is a garter snake or a water snake has not been resolved beyond doubt and deserves further study.

As for the ribbon snakes, *T. proximus* and *T. sauritus* have long been recognized as being somewhat aberrant within the genus *Thamnophis* on the basis of mensural, meristic, visceral, and molecular data (Dowling et al. 1983; Rossman 1963; Rossman et al., *in press*; N. Rossman et al. 1982) and this new character simply adds to the array. One hopes that a phylogenetic analysis of morphological characters (Rossman, Boundy, and Good, in progress) will help resolve the status of the ribbon snakes—and *T. validus*, as well.

TABLE 1. Relative height of the first dorsal scale row (maximum vertical height of DSR 1/maximum width of vertebral row) in 39 species of *Thamnophis* and *Nerodia*. Where no statistically significant sexual dimorphism was revealed (NS), values for males and females were combined. Each set of values includes mean ± standard deviation, range of variation (in parentheses), and number of specimens.

Some Aspects of the Ecology of *Pseudis paradoxa* from Northeastern Argentina

During the past seven years, we have made an attempt to gather species diversity data in an ecological preserve in northeastern Argentina (Yanosky et al. 1993). Ecological data have been taken on 32 species of anurans. One of these is the paradoxal frog, *Pseudis paradoxa*. In the Argentine Chaco, this frog breeds in temporary ponds and the tadpoles reach rapid maturity and transformation. Yet in permanently wet areas, the tadpoles reach enormous proportions (up to 220 mm), and at transformation they are of adult size (Cei 1980; Emerson 1988).

Cei (1980) states that *P. paradoxa platensis* is typically found in permanent marshes alongside major rivers and lagoons. It feeds upon small frogs and aquatic insects. Mating seems to be highly correlated with sudden rainfall or other seasonal events.

Egg laying occurs in this environment and frothy masses of greenish eggs are laid at random among the aquatic plants of the shores. The hatched larvae retain a greenish color on their venters for several days following hatching.

We present data on breeding activity of adults and ontogenetic pattern change among the tadpoles of a northeastern Argentine population of *Pseudis paradoxa*.

Results.—Pseudis paradoxa was heard calling for the first time at 1800 h, on 26 November 1993, in a vegetated pond at the entrance to the El Bagual Ecological Reserve Station. This animal was later captured on the same night with a dip net as it called from a floating position with only the eyes, nostrils, and vocal sac visible. This individual called over a water depth of 55 cm. It measured 53 mm SVL and weighed 15.8 g. During 30 November a large chorus of *Pseudis* was heard calling for the first time from two artificial ponds near a road. On the night of 1 December, amplexing pairs were seen on the surface of the water with and without floating vegetation. Ten floating amplexing pairs were observed at various depths of water as follows: two pairs were observed at 70 cm deep, two at 50 cm deep, three at 40 cm deep and three at 20 cm deep, with air temperature of 17°C at 2300 h. These 20 individuals were captured. The female and male weights and SVL measurements are 13.5–18.0 g (mean = 14.9), 9.0–15.5 g (mean = 12.9); 47–59 mm (mean = 51.8), 45–53 mm (mean = 49.9), respectively. They begin calling at dusk (near darkness) and continued through the first hours of the night. On several non-rainy days following rains, *Pseudis* called during daylight hours (morning and afternoon). The initial call was heard 26 November after the rainy season began on 12 November 1993. Individuals called through the remainder of November, all of December, and the two first weeks of January. In general, choruses were heard from most water bodies by 3 December. Maximum time period between first rain of the season, first possible appearance of eggs and metamorphosis is 12 November to the first week of January (about 50–56 days). However, since *Pseudis* vocalizations were not heard prior to 26 November, using the latter date as the first attempt to call and mate, development takes about 40 days.

Tadpoles were found in artificial and natural pools between 10–15 cm to 70–80 cm deep. The tadpoles were found throughout the water column, observed singly, and cohabit ponds with a large number of other anuran tadpoles. During periods of no rainfall, early stages of small tadpoles were continuously found, agreeing with observations for continuous calling and mating.

Tadpole growth in captivty is very slow. The larvae are motionless most of the time at the bottom of the water column and feed on vegetables and goldfish food.

Pseudis paradoxa tadpoles show an ontogenetic shift in color pattern from stage 25 through stage 38. The smallest tadpole (5 mm, stage 25) is almost colorless, but by a total length of 7 mm (stage 25) the tadpole appears to have three black spots: one spot just behind the body on the dorsal muscle and part of the dorsal fin, the second as a black spot in the tail muscle about midway from body to tip of tail, and the third spot at the tip of the tail. Tadpoles 10–15 mm in total length (stage 25) tend to have the anterior black spot extending downward and anteriorly across the body, the middle spot has formed a narrow bar that progressively extends above and below the tail muscle, and the tip of the tail black spot is expanding forward. As the tadpole grows in length and weight, the most posterior black spot (tail tip) spreads anteriorly, eventually creating a blackish tadpole. An illustration of the ontogenetic pattern differences of the *Pseudis* tadpole from stage 25 (21 mm TL tadpole) to stage 26 (76 mm TL tadpole) (Gosner 1960), is presented in Figure 1a–1e, and described below for additional stages.

Stages 21–25: A tadpole with a transparent tail changes to a tadpole with a transparent tail with small dark spots and three vertical black bars, one in contact with the body, a median one and the third near the tip of the tail. All specimens contain a black stripe from the mouth to the eye, and a dark dorsal wedge between the eyes to the tip of the snout, bordered by two conspicuous white lines. Measurements for one specimen are: TL = 45.7 mm; BL = 15.1 mm; MBH = 13.9 mm and W = 0.8 g.

Stages 26 and 27: The posterior half of the tail turns black beginnning with individual tadpoles 46 mm long. Cephalic white lines are not as pronounced as observed in previous stages. The cephalic lines are absent in stage 27. Depressions occur along each side of the dorsal fin, from its insertion on the head to the posterior part of the body. There is great variation in size individually and the transparent parts of the fin are not clearly visible, because of dense dark spots. Measurements of one speci-

men are: TL = 59.1 mm; BL = 16.5 mm; MBH = 18.2 mm and W = 1.35 g.

Stage 28: The black vertical bars in the tail have disappeared and the tail is almost completely black. In animals 68 mm long there is a very dark border on the ventral side of the fin. The posterior end of the tail is no longer black but intensely black spotted. Head depressions are very evident. Measurements for three individuals are: TL = 70.3, 73.2 and 68 mm; BL = 21.5 mm, 22.5 and 19.3 mm; MBH = 24.4 mm, 27.7 and 22.2 mm; W = 3.15, 4.4 and 2.6 g.

Stage 35: Head depressions are present and the dorsum is greenish. Measurements for two specimens are: TL = 67.1 and 62.3 mm; BL = 23.3 and 23.2 mm; MBH = 24.7 and 24.8 mm; W = 7.8 and 4.05 g.

Stage 37: Head depressions are present, dorsum greenish and the anterior part of the belly is olive, passing posteriorly into light brown, pearl silver, and eventually pinkish. The black border on the ventral side of the fin is very evident. The fin is now "tiger spotted." Measurements for two specimens are: TL = 96 mm and 76.2 mm; BL = 25 and 24.4 mm; MBH = 28 and 25.5 mm; W = 6.5 and 5.3 g.

Stage 38: The cephalic depressions are deeper; the dorsum becomes more green; the body and tail become less blackish and with many small dark and rounded spots. Measurements of one individual are: TL = 92 mm; BL = 34.2 mm; MBH = 37.6 mm; W = 13.5 g.

In summary, between stages 34 and 38, (TL between 76 and 135 mm), there is a progressive loss of black pigment. The black spots or tiger-like markings become progressively smaller, until there is an almost greenish-like tadpole with obscure brownish or dark gray body markings. The pronounced "valleys" on either side of the insertion of the tail fin onto the head and body are strongly evident.

Discussion.—Kehr and Basso (1990) present a description of the *Lysapsus limellus* tadpole. They note that the tip of the tail is colorless at stage 28, but progressively becomes black between stages 30 and 39. However, in this species of *Lysapsus* the black tail spot never exceeds 25% of the tail length. Caldwell (1982, 1986) stated that the black tail spot may function as disruptive selection to avoid differential predation pressures. This hypothesis was tested by Caldwell (1982), and under the constraints of the laboratory tests, was supported. In her experiments, Caldwell used populations of *Acris* with and without black tail tips. If we assume that all water bodies at the site contain equal numbers of aquatic insect predators (all tadpoles were patterned with black), then the ontogenetic pattern changes of *Pseudis* tadpoles may carry them beyond certain differential predation limits. However, populations of *Pseudis* tadpoles may be polymorphic. Cei (1980) illustrates a 94 mm total length *Pseudis paradoxa* tadpole without black tail spots. However, without prior knowledge of the locality of Cei's tadpole or of other possible color patterns, this pattern type may support Caldwell's (1982) hypothesis of differential predation pressure, which depends upon water depth, type of predator, and permanency of water.

Emerson (1988) discusses various aspects of tadpole size and patterns of development of *Pseudis paradoxa*. Emerson describes giantism as a possible function of two hormones, thyroxine and prolactin. A hypothesis is presented concerning these hormones, but the hypothesis is not testable at this time. Tadpole size is often independent of tadpole stage in the Argentine sample of *Pseudis paradoxa*. For example, total lengths of tadpoles in stage 25 vary from 5–46 mm, stage 35 vary only from 62–67 mm, while at the same time total lengths of tadpoles in stage 26 may reach 76 mm. It seems that length (and weight) of *P. paradoxa* tadpoles

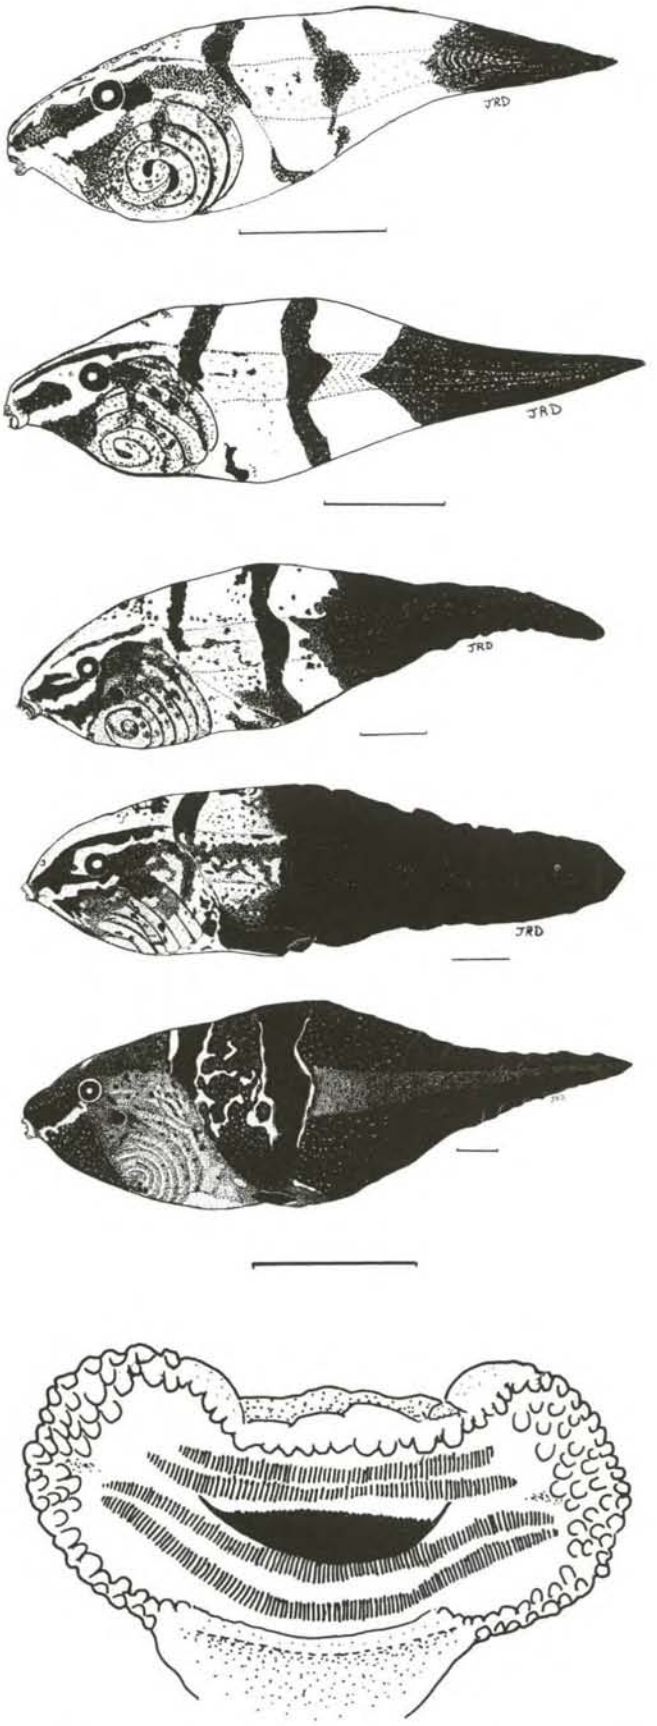

FIG. 1. Ontogenetic pattern of *Pseudis paradoxa* tadpoles at (a) 21, (b) 27, (c) 44, (d) 52, and (e) 76 mm total length, from a temporary pond on El Bagual Ranch, Formosa, Argentina. Tadpoles represent Gosner (1960) stages 25–26, and the black bar = 5 mm. Figure 1f represents a view of the tadpole mouth parts.

may be a function of available food and environmental temperatures, independent of developmental stages.

Acknowledgments.—We want to thank Gustavo Carrizo and Dante Paz for their help during this project. This is Scientific Contribution # 79 for Alparamis Sa., El Bagual Ecological Reserve Pty.

Fire Ecology of the Florida Box Turtle, *Terrapene carolina bauri*

The effects of habitat fires, both natural and those caused by humans, on amphibian and reptile populations have been of some recent interest (Mushinsky 1985, 1986, 1992; Mushinsky and Gibson 1991; Mushinsky and Wirtz 1993; Patterson 1984). In Florida the influence of periodic burning is especially important in the pine flatwoods and dry prairie ecosystems (Abrahamson and Hartnett 1990). Natural fires maintain the habitat as a stable and essentially nonsuccessional association; however, human alteration of the natural fire frequency commonly brings about rapid successional changes in these ecosystems (Monk 1968; Peroni and Abrahamson 1986; Richardson 1977). The major natural cause of these wild fires is a lightning strike (Abrahamson et al. 1984), and fires were common in pre-1900 Florida before human structures such as roads, cultivated fields, or urban developments limited the amount of area burned (Abrahamson 1984). Originally, most natural fires probably occurred during the summer dry period from June to September allowing for recovery during the rest of the year, but currently managed burning also occurs during the dry winter season (Abrahamson and Hartnett 1990). These changes in the frequency of burning, in addition to human agricultural and urban development, have brought about a decrease in the total area of the pine flatwoods and dry prairie ecosystem in Florida. The end result of this activity has been a reduction in the available critical habitat of some amphibian and reptile species.

The Florida box turtle, *Terrapene carolina bauri*, ranges over most of central and eastern peninsular Florida and the Keys (Ashton and Ashton 1985; Ernst et al. 1994; Iverson and Etchberger 1989). Carr (1952) also reported it to be most abundant in the limestone flatwoods of southern Dade County. Over the range of *T. c. bauri*, the flatwoods habitat with which it is best associated (Abrahamson and Hartnett 1990) is subject to periodic burning. To what extent is the Florida box turtle adversely affected by such events?

While examining a series of *T. c. bauri* in the collections of the United States National Museum of Natural History, Smithsonian Institution (USNM), and George Mason University (GMU), a relatively large proportion (30%) of the specimens exhibited burn damage to their carapace. This damage was manifested as extremely scarred or warped areas on the carapacial scutes and often included the underlying bones. The USNM and GMU collections contain over 1000 specimens of *T. carolina*, representing all six known subspecies (Ernst and McBreen 1991b), but no other subspecies had as many fire damaged individuals (< 5% each in those from the United States), possibly indicating that fire plays a more important role in the ecology of *T. c. bauri*.

All *T. c. bauri* examined were adults. Carapace length and height were analyzed using a large sample approximation of the Mann-Whitney U-test. Both carapace length and height were found to be sexually dimorphic in an overall comparison of males and females ($Z = -4.07$, $p = 0.05$; $Z = -2.26$, $p = 0.05$, respectively) and in a subsample of unburned males and unburned females ($Z = -2.58$, $p = 0.05$; $Z = -2.02$, $p = 0.05$, respectively). However, in comparing burned males with burned females, carapace length, but not carapace height, was sexually dimorphic ($Z = -2.54$, $p = 0.05$; $Z = -1.19$, $p = 0.05$, respectively). Observed differences in carapace length, height, and age of burned and unburned males and females are provided in Table 1.

Sexual dimorphism in carapace length and height is well documented in the genus *Terrapene* (Ernst et al. 1994; Ernst and McBreen 1991a, 1991b; Milstead 1969); however, it does not address whether age, size, or sex influence the probability of being damaged by fire. A chi-square test of independence was used to determine if sex and burn damage were independent of age class or size (carapace length and height). Age classes identified were < 15, 16–20, > 21 years, and the size classes (in mm) used were 105–120, 121–135, and > 135 for carapace length and 50–60, 61–67, and > 68 for carapace height. Comparisons between various group combinations are presented in Table 2. The results indicate that age group and carapace height are independent of fire damage, but that carapace length is not. Since carapace length is not independent of fire damage when comparisons are made between both burned and unburned animals and burned females and burned males, it is possible that wild fires do not randomly affect adult populations of *Terrapene c. bauri*. Fossorial Floridian lizards and snakes occupying burrows have high survival rates during fire events (Mushinsky 1985; Mushinsky and Wirtz 1993). *Terrapene c. bauri* does not dig a subterranean burrow. However, it does construct a shallow form in litter for sleeping and aestivating (Ernst, pers. obs.), and it is likely most turtles that survived burning occupied such forms. This is supported by the location of burn damage on carapace, which was generally limited to the neural and anterior costal bones. The Florida box turtle will enter other animals' burrows, and those lucky enough to be underground at the time of a fire are probably unharmed. Those individuals caught in the open are likely killed. Hatchling and juvenile *T. c. bauri* usually hide under litter (Ernst, pers. obs.), and such behavior would not favor survival in the event of fire.

TABLE 1. Sizes and ages of *Terrapene carolina bauri* examined.

		Burned Males	Burned Females	Unburned Males	Unburned Females
CARAPACE LENGTH					
	N	13	19	36	35
	Mean (SD)	139.1 (10.1)	128.8 (9.4)	140.8 (17.1)	130.3 (11.0)
	Range (mm)	117.4–155	112.8–145.5	105.1–198.2	109.1–166.4
CARAPACE HEIGHT					
	N	12	19	35	34
	Mean (SD)	64.3 (4.8)	67.4 (5.1)	66.6 (6.9)	68.3 (5.2)
	Range (mm)	57.4–75.6	54.5–77.0	52.5–89.6	57.1–79.1
AGE					
	N	13	19	36	35
	Mean (SD)	19.6 (5.7)	21.4 (6.1)	18.4 (5.9)	20.4 (6.2)
	Range (mm)	13–27	12–27	10–27	9–27

The above observations indicate that fire may play a critical role in the ecology of Florida box turtle populations. Unfortunately, so little has been published on the life history of this animal that it is difficult to assess its ecological and behavioral requirements with any degree of certainty. A thorough study of this turtle in view of its fire-related ecological consequences would be worthwhile.

RECENT POPULATION CHANGES

Historical Distribution, Current Status, and a Range Extension of *Bufo boreas* in Utah

The boreal toad (*Bufo boreas*) is proposed for Federal protection as a Category 2 species, under the Endangered Species Act. This listing indicates the species may be threatened or endangered with extinction due to declining populations in Colorado, New Mexico, and Wyoming (Federal Register 1991). In Utah, the distribution and status of this toad are unknown, especially in southern Utah (Stebbins 1985). Amphibian populations in portions of the western United States are experiencing rapid declines (Bradford 1991; Corn and Fogelman 1984; Fellers and Drost 1993). Carey (1993) discussed the disappearance of *B. boreas* due to disease and interrelated factors in Colorado.

Early accounts and collections portray *B. boreas* as a common toad in some areas of Utah. Tanner (1931) described *B. boreas* as being "far more common in the northern part of the state than in the southern. It is the common species in the canyons and mountains of central and northe[r]n Utah." Woodbury (1952) wrote that this species is "known from the northern portion" of the Great Salt Lake Valley and is a "common 'garden' toad." Tanner (1931) found *B. boreas* "common around the shores of Great Salt Lake." Van Denburgh and Slevin (1915) collected 87 specimens from five locations in Salt Lake and Utah counties. Slevin (1928) reported *B. boreas* from Juab and Summit counties. Records in the University of Utah Museum of Natural History indicate 10 specimens were taken from one site in Wasatch County on 12 July 1959. While Hardy (1938) described this species as "common in the Colorado River drainage in Sevier and Wayne counties" in southern Utah, there are only 4 museum records from those counties. Hardy (1938) also wrote that *B. boreas* was "not common in Carbon County" in southern Utah.

We queried 57 institutions in the United States for their holdings of *B. boreas*. Twelve institutions reported a total of 100 specimens from 52 localities in Utah (Fig. 1). All museum material was collected prior to 1971. Museum records for which elevation data were available (N = 29) ranged from 1374 m to 3136 m in elevation. Museum acronyms follow Leviton et al. (1985).

We found 22 localities in unpublished reports and personal communications. We queried two professional biologists who collected or observed amphibians in boreal toad habitat. There is one report of *B. boreas* in southern Utah (F. Turner, pers. comm.). While records are lacking in adjacent Nevada (Linsdale 1940), the nearest record is about 150 km northwest of this observation. Turner (pers. comm.) also observed *B. boreas* at four locations in northern Utah (Fig. 1).

The majority of historical locations were from northern Utah (Table 1) and may reflect collection effort. We (P.H. or D.A.R.) last observed evidence of reproduction (tadpoles or juvenile *B. boreas*) in three sites between 1982 and 1988 in northern Utah (Fig. 1). At least one subsequent survey was conducted at each of these sites. Tadpoles (N = 200) were also observed at one site in northern Utah (Pederson 1977a). Other recent observations of *B. boreas* in Utah are scattered and usually are of one to several adults (Fig. 1). In 1976, four adults were observed in northern Utah (Pederson 1977b). Two observations at a separate locality in northern Utah during 1978 through 1980 were reported by Shields and Moretti (1982).

TABLE 1. Number of historical locations, number of locations resurveyed, and number of sites occupied by *Bufo boreas* in northern and southern Utah. New sites are indicated in parentheses and number of occupied sites with evidence of reproduction (i.e., egg masses, tadpoles) is given in parentheses.

	Number of Historical Locations*	Number of Resurveyed Sites	Number of Occupied Sites
		Northern Utah	
	64	5	0
	(3)	—	3 (2)
		Southern Utah	
	7	3	0
	(3)	—	3 (2)
Totals	71	8	6

*Specific locality information may be acquired by contacting the Aquatic Section, Utah Division of Wildlife Resources, Salt Lake City.

Early literature (Tanner 1931) alludes to the presence of *B. boreas* along the Great Salt Lake (Salt Lake County) and Utah Lake (Utah County). Our search revealed no museum records within 17 km of either of these localities. We believe that *B. boreas* occupies montane habitats and sometimes valley wetlands adjoining montane habitat but does not use valley habitats distant from mountains. One report from southern Utah (Tanner 1927) is not represented by a museum specimen.

Three new locations represent southern extensions of the range of *B. boreas* (Fig. 1). The first locality is from 2500 m in elevation. We (RAF, TCE, DAR) observed adult toads (N = 70) at several beaver ponds and egg strings (N = 35) in 5 ponds in 1994. Metamorphs (about 17 mm SVL) were observed at two of these ponds during July. We (RAF) observed adult *B. boreas* (N = 15) and numerous metamorphs at a second new locality at 3030 m in elevation during 1994. We observed adult *B. boreas* (N = 3) at a third new locality at 2803 m in elevation during 1994.

Based on these limited observations, the current distribution of *B. boreas* in Utah is not well documented. Montane habitats in southern Utah are disjunct (Wahlquist 1981) and, as such, may predispose *B. boreas* populations to extirpation as a result of anthropogenic factors. Surveys should be expanded and continued to determine the distribution and population status of this anuran, and factors affecting its populations.

Acknowledgments.—We thank F. B. Turner for the use of his unpublished data, and E. A. Rickart (UU), J. W. Sites, Jr. (BYU), J. W. Wright (LACM), P. W. Hyder (NMSU), S. M. Moody (OUVC), J. P. Rosado (MCZ), D. B. Wake (MVZ), W. E. Duellman (KU), E. V. Malnate (ANSP), C. M. Dardia (CU), R. G. Webb (UTEP), and W. R. Heyer (USNM) for providing data from their respective collections. We thank the following persons for time donated searching for toads: K. Dean-Bradley, L. DeFalco, R. Espinoza, J. Jennings, K. McDonald, and M. Nijhuis.

TECHNIQUES

Experimental Use of Remotely-triggered Cameras to Monitor Occurrence of Timber Rattlesnakes (*Crotalus horridus*)

Populations of *Crotalus horridus* are in decline across the northeastern U.S. (Brown 1993), and assessment of the density of specific rattlesnake populations is important. Clipping ventral scales and painting rattles will identify individuals, but recapture is often difficult; snakes are averse to handling and may avoid areas of capture (Brown 1992). Radiotelemetry has been successfully employed to study habitat use (Reinert 1993), but is expensive and time-intensive. Deployment of remotely-triggered cameras at potential den and basking sites is a less intrusive and time-intensive method of studying rattlesnake populations.

To determine whether an infrared beam transmitter would alter rattlesnake behavior, we placed an active infrared-beam transmitter (TrailMaster® TM1500, Lenexa, Kansas 66215, USA, [not an endorsement of product] game monitoring system [Kucera and Barrett 1993]) and a neutral object of the same size near a captive rattlesnake in an enclosure. The snake investigated, but did not display aversion to, or exhibit prolonged interest in, either unit. When the infrared receiver and transmitter were positioned so that the snake would have to cross the beam to reach a dead rodent provided for food, the snake crossed the beam, tripped the camera, and fed at a normal rate. A second feeding followed the first and, again, the snake's behavior appeared normal.

Three sites where timber rattlesnakes had either been observed or where shed skins had been found recently were each monitored with two TrailMaster® systems for twelve days. Another site known for rattlesnake use was monitored for one week with one unit. The four sites included a talus slope with 50% canopy, a large level rock slab with potential as a basking site, and two crevices at ground level below massive rock outcrops.

Monitoring units can be programmed to optimize the likelihood of recording the desired species. A medium sensitivity setting of 10 was optimal for recording rattlesnakes and prevented blowing leaf litter, moving shrub stems, heavy fog or rain from activating the monitor-connected cameras. A 35mm, motor-driven, auto-focus/flash/advance Olympus camera with a 50mm lens was supplied with the system. A delay of 15 minutes between exposures prevented using the entire roll of film during any one activity period.

Problems unique to deployment of units at ground level in rattlesnake habitat included disruption by curious animals, pooling of rain water, and excessive exposure to sunlight. Cameras placed on a rock slab were tipped and their wires disconnected by shedding snakes (skins were found nearby) or other animals. Building a small rock cairn around the camera and tripod, and taping or caulking the wire connections, prevented recurrences. In areas with talus we positioned the camera above the site by strapping the camera to dead limbs with velcro straps and placing the limbs across rocks.

The transmitter/receiver units are designed to be strapped vertically to trees so that rain will not enter a small opening on the bottom of the units which maintains normal internal pressure over

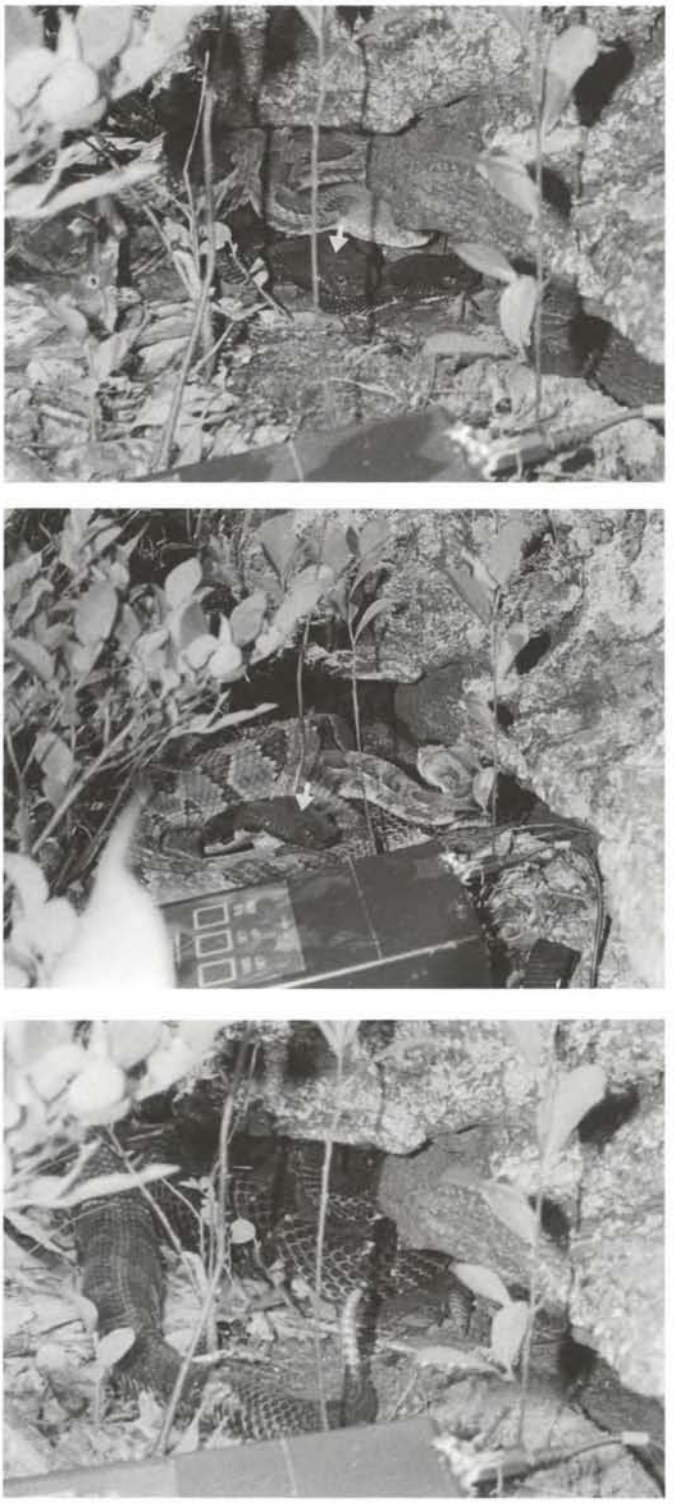

FIG. 1 (a–c). Photographs taken by remotely-triggered camera stations. 1a (top): heads of *Crotalus horridus*. 1b (middle): two *C. horridus*, one with same scar appearing in 1a. 1c (bottom): rattle segments can be counted to approximate ages of individuals.

a range of temperatures. Since we needed to place the units horizontally on the ground with the beam closely parallel to the surface, we silicone-caulked wire connections and pointed the bottom of the units downward on any incline, avoiding areas where puddling could occur. None of our units was damaged by rain but the manufacturer recommends enclosing the transmitter and receiver in clear plastic bags and taping the open end around the wires.

Bright sunlight can interfere with the infrared beam and overheat the units. Our best results were achieved at a site where the receiver and transmitter were placed in partial shade. The beam monitored only one meter along the interface between rock outcropping and the ground where snake activity had been observed. At the end of one week, 35 of 36 frames of black and white film (400 ASA) contained images of rattlesnakes. In one frame three *Crotalus* heads, one yellow and two black (Fig.1a), were together. One black and one yellow morph had been observed previously at the site, and the remotely-triggered cameras verified the presence of an additional individual after only 2 h of effort had been expended on placement and film collection. This compared with 8.7 person-hours of active search effort for each of the other individual snakes recorded. Camera and receiver recorded date and time of events; a scar on the head of one snake identifies the same individual in separate photographs (Fig.1b). In other frames, rattle segments can be counted (Fig.1c) providing some indication of age of snakes. Use of color film, although more expensive than black and white, would allow for identification of specific individuals because of unique coloration and patterning.

Camera units also recorded nighttime use of the rock slab by a bobcat (*Lynx rufus*), raccoons (*Procyon lotor*), and an unidentified bird. In the talus, mice (*Peromyscus* sp.) and squirrels (*Sciurus carolinensis*) were often recorded.

The presence of units at a site may attract attention leading to the harassment or capture of the snakes and is not advisable in areas with high human visitation. Because rattlesnake dens are frequented by poachers and collectors, theft of camera units is also a distinct possibility. Use of this system to monitor remote sites on a daily basis over an extended period of time, however, is worthwhile. Given the low population densities of some endangered species, documentation of even one more living individual at a site is important.

Acknowledgments.—Equipment was provided by the Northeastern Forest Experiment Station and funding was provided by The Nature Conservancy and the Massachusetts Natural Heritage and Endangered Species Program. We thank Alan Richmond for suggestions for the captive snake experiment, and the staff at the Massachusetts Audubon Society Laughing Brook Education Center in Hampden, Massachusetts for assistance. We are also grateful to Frank Lowenstein, manager of the Berkshire chapter of the Nature Conservancy, to Christopher Weaver and Heather Lanza for their support in the field, and to R. R. Stechert for invaluable advice regarding *Crotalus*.

Radio Transmitter Attachment for Turtle Telemetry

Variations in chelonian size, differences in behavior and habitat preference, and diverse research goals pose problems for fastening radio transmitters to turtles. Transmitters glued to turtles with aquarium sealant are quickly dislodged in the field; the bond from 5-minute clear epoxy deteriorates within one season (D. C. Holland, pers. comm.). Some fast-setting epoxies create a strong bond between transmitter and scute, but can emit enough heat to pose a burn hazard to underlying tissue (Renaud et al. 1993).

PC-7 (Protective Coating Co., Allentown, Pennsylvania, USA) is a slow-setting epoxy that emits no significant heat and secures material to scutes with a bond that endures for years. PC-7's viscosity will also hold a transmitter in place as it dries, and this simplifies application. Attachment with PC-7 (best started at night, so the epoxy can cure when the turtle is less active) proceeds as follows:

1) Thoroughly clean the attachment site with ethanol and a tooth brush (phenolic impurities are highly toxic to turtles [Hillyer 1993]).

2) Use thin strips of masking tape to cover all scute junctions near any area to be epoxied. Growth occurs at these boundaries and rigid adhesives (like PC-7) must not span them.

3) Lay a ring of caulking down along the perimeter of the scute to receive the transmitter. Reusable winter window caulking "rope" (FROSTKING FINGERTIP CAULK by Thermwell Products Inc.) is ideal for constructing this rim. The rim helps prevent epoxy from extruding onto neighboring scutes when the transmitter is pressed into place.

Aquatic Turtles.—For aquatic species, on which attached instruments can serve to snag and drown the turtle, the procedure continues as follows:

4) Apply epoxy within the caulk rim on the target scute and gently press the transmitter (AVM Instruments, Livermore, California, USA) into the well of epoxy. Do not apply pressure to the transmitter coils (red coiled wires) as this can detune the unit.

5) Epoxy the antenna in as wide an arc as possible just inside the marginal scutes. Trim the antenna to ensure that its arc will not constitute more than 75% closure of a circle when in its final position. A transmitter's signal is muted if the antenna's tip nears its base. To preclude snagging on underwater twigs, the unepoxied antenna segments at all scute junctions must be covered; a pliable adhesive like 5-minute epoxy should be used on these narrow interstices.

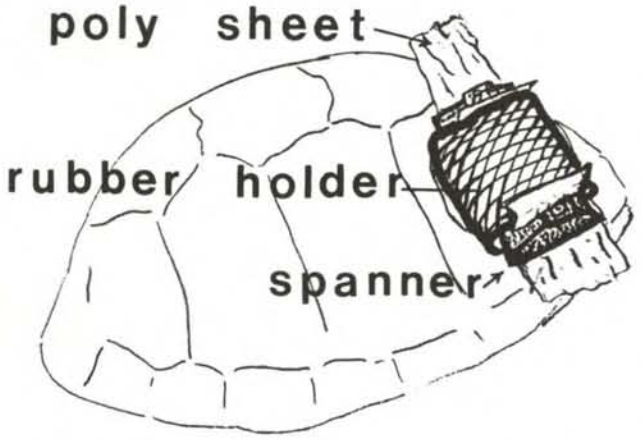

FIG. 1. Rubber holder with openings oriented laterally; plastic spanner in position.

While PC-7 provides a reliable bond that endures aquatic stress, it does make replacing transmitters difficult. Prying an old transmitter off can tear scutes bonded to the epoxy. Begin the removal process with a Dremel drill (with an emery cutting wheel), and follow the drill with a jeweler's saw to safely separate transmitter from scute. This is faster (one hour per transmitter) than using only a jeweler's saw to slice through the epoxy. An exacto knife will gently tease any epoxy residue off the scute.

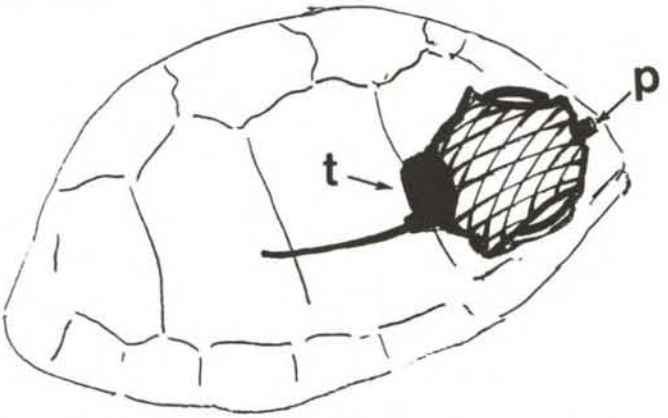

FIG. 2. Battery positioned within rubber holder; transmitter (t) projecting from posterior hole (at left) and anchoring pin (p) protruding through anterior puncture (at right).

Terrestrial Turtles.—For terrestrial turtles, our method can be adapted, after step 3, as follows:

4) Apply a thin patch of PC-7 epoxy within the putty rim on the target scute (on male box turtles, vertebral scute #2 is used; on females, pleural scute #1 is used instead, so the attached transmitter will not impede mounting by courting males). Work the epoxy into the scute's surface irregularities.

5) Cut a 3 cm length from a 1.25 inch bicycle inner tube. Make 3 to 5 holes of approximately 4 mm each in what will serve as the bottom half of this 3 cm rubber ring. The holes will allow epoxy, extruded from inside the ring in step #8, to bond the rubber holder to the expoxy on the scute.

6) Line the interior of the rubber ring's top half with tape and polyethylene to preclude its getting glued to the bottom.

7) Set a wad of epoxy on the center of a 3.5 cm x 8 cm polyethylene sheet. With its epoxy side down, slip one of the long ends of poly sheet into, and through, the rubber ring and draw the sheet into the ring until the epoxy is directly over the holes.

8) Coat a hard 3 cm x 4 cm plastic rectangle with vegetable oil so it can not adhere to epoxy. Slip this oiled plastic spanner into the narrow space above the polyethylene sheet's upper, clean surface. The space that the spanner creates between the sheet and the ring's roof further reduces the risk of gluing the ring's rubber walls together (Fig. 1). Insertion of the spanner extrudes epoxy through the holes in the bottom of the rubber ring, and out of its two ends.

9) Press the ring down, with its holes facing toward the carapace, onto the prepared scute. To ensure a strong bond, gently rotate the assembly to blend ring and scute epoxies. Orient the ring's blind ends sagittally, and its open sides laterally (Fig.1), so the antenna will emerge posteriorly in Step #11 (Fig.2).

10) After 12 h of epoxy curing, remove the plastic spanner and as much of the polyethylene and tape shielding as possible from inside the rubber ring. Cut a 1 cm hole in the posterior end of the rubber holder, and make a small puncture in its anterior end.

11) Thread the antenna, and then push the transmitter through the posterior 1 cm hole. The posterior hole's perimeter grips the

transmitter tightly. The short metal pin (built into the unit, upon request, by AVM Instruments) projecting from the end of the battery opposite the transmitter will anchor the anterior end when slipped into the puncture at the front of the rubber ring (Fig.2).

12) This secured rubber holder enables simple, fast (2 min) field replacement of transmitters. Covering the assembly with duct tape will protect the rubber from twig snags and abrasion.

Acknowledgments.—We thank the San Francisco Foundation, Switzer Fellowship Program, for funding that enabled the initiation of the western pond turtle studies at the Pepperwood Ranch Natural Preserve in Santa Rosa, California, and anonymous contributors and the Clarion University Foundation Projects Committee for funding that enabled initiation of the box turtle repatriation project at McKeever Environmental Learning Center in Sandy Lake, Pennsylvania. Thanks also go to Mary Beth Steisslinger for field work in Pennsylvania, and to Bill Lutz and Venango Newspapers Inc. for image processing.

Österreichische Gesellschaft für Herpetologie, c/o Naturhistorisches Museum, Burgring 7, A-1014 Wien.
Membership fee per annum: US$ 35.-.
We would charge your VISA card.

WANTED: HERPETOLOGISTS OR SNAKE KEEPERS. For part-time on-call work to begin in 1996 season in your area. MUST HAVE at least 5–10 years experience working with or extensive knowledge about snakes indigenous to your area, reliable transportation, flexible hours, telephone with answering machine. Applicants must be readily contactable, i.e., have EITHER pagers, mobile or work phones, be at least in mid-twenties and must be willing to sign and comply with terms of a No Compete-Nondisclosure agreement and a waiver of liability. Pay averages $10–15 per hour of work (some mileage will be paid for distances greater than 25 miles). For the location, capture and removal of snakes from the properties of customers as well as educating customers about snakes found in their locality, and the benefits these animals provide. Emphasis is placed on promoting the conservation of the animals by educating our customers. Looking for serious applicants from the following states and areas ONLY: MD, WV, PA, western VA, OH, IA, DE, IN, IL, MO, KY, TN, NC, GA, AL, northwestern FL, MS, AR, TX, OK, KS, NB, CO, NM, AZ, UT, NV, OR, NJ, and NY. For detailed position description and application packet/No Compete agreement, write to: Michael Weeks, 1913 Dannemora Drive, Virginia Beach, VA 23456. Please include your area code/phone number. No inquiries from pet dealers, rattlesnake round-up types, or the idly curious. Please!

HERPETOLOGICAL HUSBANDRY

Five Year Study of Nesting of Captive *Terrapene carolina triunguis*

Very little information has been published on nesting by the three-toed box turtle, *Terrapene carolina triunguis* (Dundee and Rossman 1989). Most published information is on the nesting of other subspecies of *Terrapene carolina* (Allard 1935; Carr 1952; Congello 1978; Cross 1980; Ernst and Barbour 1972; Ewing 1933; Stuart and Mullen 1987; Tucker and Funk 1977), and much of this is anecdotal. In order to obtain more information, we conducted a study from 1990 through 1994 on the egg-laying habits of this subspecies.

Materials and Methods.—The study site was located in Morehouse Parish about 40 km N of Monroe, Louisiana, USA, (32°47'N, 91°52'W), at an elevation of 45 m. Observations were conducted within a 31 x 34 m relatively flat area surrounded by a 1.23 m high chain link fence. Seven water pools (diameter = 31 cm, depth = 7.5 cm) were placed in the ground, and numerous places to hide and brumate were available. Supplemental food was provided at least once a day. Native grasses and weeds covered most of the ground. The area also contained trees, ornamental bushes, strawberry plants and, at times, mushrooms.

The turtles came from within 10 km of the study enclosure with the exception of four that came from approximately 137 km south of the area. We obtained turtles by collecting those found on roads. When one was found, we weighed it, noted any unusual characteristics, and released it within the study area. The turtles varied considerably in their coloration and markings, and we used those differences to identify individuals. A camcorder was used to record nesting behavior.

We weighed 61 mature, healthy adult turtles. The mean (± SE here and elsewhere) body mass of the females was 456 ± 6 g (range 323–658, N = 37), and the mass of the males was 350 ± 7 g (range 276–414, N = 24).

During the study 35 females were observed; 7 for the entire five-year study, 6 for four years, 3 for three years, 3 for two years, and 8 for one year. The remaining 8 were observed for only a portion of one egg-laying season.

We attempted to record every clutch laid by watching the females each evening from early May through mid-August. Because we were unable to observe them during parts of the morning and afternoon, and because some females nested in places difficult to discover, some nests could have been missed. We patrolled the study area at about 15-minute intervals from 1600 h until dark. The area was searched again at 2200 h. When we discovered a female digging we marked the location of her nest while she was at the site. The next morning we covered the nest with a square of hardware cloth and labeled it with the turtle's identity and the date of oviposition. After about 60 days, we replaced the hardware cloth with a domed aluminum colander (diameter = 20.5 cm) so the neonates would not be trapped inside the nest. If neonates did not emerge after 80–102 days (depending on the temperature and location), we opened the nests.

Results: *Nest Site Selection.*—A female typically began searching for a nesting site after 1600 h. She searched slowly, examining the earth. Many times she paused, scratched the surface with her front feet and "smelled" where she had scratched. If the spot was acceptable, she moved forward so that her back legs were over the spot she scratched. She then began to dig a nest with her hind feet, alternating between feet. Sites were sometimes abandoned if roots or other hard objects were encountered, or if the nest cavity broke into a tunnel made by a crayfish or other animal. A hard rain storm generally caused a female to abandon a nesting site, but light rain showers did not seem to interfere. Sometimes nests were abandoned for no apparent reason.

Aggressiveness by female *T. carolina* during the nesting season was reported by Zeiller (1994). Similarly, we found that several females became aggressive and restless just prior to laying their eggs; we observed this behavior at no other time. Two females were especially aggressive toward other females that were searching for nesting sites. On several occasions they appeared to attempt to push other females from their nesting sites.

We observed, as did Pope (1939), that if a female had lost a part of a back leg, she would still try to dig with the nub. In that event the nest would not be as large as a nest dug with two back feet. Frequently the nest was not large enough for all of her eggs. In such cases, one or two eggs would be left lying on the ground near the nest.

TABLE 1. A comparison of the lengths of internesting intervals and number of clutches laid per season for three-toed box turtles in Louisiana. Mean = mean internesting interval (days) ± SE. N = total number of intervals.

Clutches per season	Mean (days)	Range	N
2	22.0 ± 6.3	16–33	5
3	20.8 ± 4.7	14–38	46
4	18.4 ± 3.1	14–25	36
5	18.9 ± 3.9	14–24	8
6	16.1 ± 3.7	12–24	10

Most females did not lay the first evening they began to search. Frequently a female began two or three nests in one evening, but left them unfinished. The following evening she would again attempt to nest. Of the 243 clutches observed, only 30% of the clutches were laid the day that the female began to search, 22% the second; 16% the third; 11% the fourth; 7% the fifth; 4% the sixth and the remaining 10% later.

There was a considerable variety in the locations and substrates that females attempted to use for nesting. Most clutches were laid in open areas that received direct sunlight during a portion of the day, but a few were laid in areas that never received sunlight and under bushes in the loose soil of flower beds. Two females attempted to dig nests on a concrete patio.

There was some variability in the way individual females dug their nests. Most carefully lifted dirt from the hole with the hind feet and laid it behind the hole; however, one female threw dirt 30 cm or more behind her. She did not continually hold her position with her front feet, but rotated some 270° around the hole as she dug. With few exceptions, excavated nest cavities were flask-shaped. The size of the nest cavities appeared to be determined by how far the female could reach with her hind legs, as she seemed to dig as long as she could reach soil and remove it from the hole.

Oviposition.—The nesting process normally took several hours to complete (Allard 1935; Carr 1952; Ernst and Barbour 1972). When the typical female had completed nest excavation, there

was a crescent-shaped pile of loose dirt behind the hole. After the nest was excavated, the female continued to put one back foot and then the other into the hole. After a short time, she fully extended her head, then retracted her neck, pulled her head into her shell, and strained to push an egg from her body. Sometimes a female appeared to have difficulty laying an egg and she strained for extended periods of time. On 24 occasions we recorded oviposition of 11 different females using a camcorder. The mean amount of time between the laying of two eggs was 203 ± 17 s (range 60–574, N = 55, median = 166 s).

Covering the Nest.—The typical female started covering her eggs about a minute after laying her last egg. She did not begin by using the dirt evacuated from the nest, but instead reached forward with her rear feet to the area near the bridge of her shell and raked grass and/or litter from the surface of the ground into the nest. After packing a mixture of soil and organic material into the egg chamber, she finished covering the nest by utilizing the soil excavated from the hole. This method explains the previously observed difference in density between the soft material surrounding the eggs and the hard-packed dirt in the "neck" of the flask-shaped nest (Zeiller 1994). The soft material around the eggs may aid in the emergence of the neonates from the nest (see below).

At times, after pulling a bit of material into the hole, the female tamped the material with the upper side of her toes. She put both feet on the material and tamped, alternating feet every 0.5 to 0.7 sec. She tamped for a variable length of time, and then returned to raking material into the hole. She alternated raking and tamping until she finished filling the nest.

Often after completion of nesting, females got into one of the water pools and sat for long periods of time, occasionally exercising her hind legs in the water. Dickson (1953) reported similar behavior.

Neonate Emergence.—The relatively soft material surrounding the eggs in the nest allowed some movement of the neonates after pipping. Movements of the neonates apparently contributed to the collapse of the cap of soil above the egg chamber, as we never found an egg chamber caved in without a live neonate inside. The collapse of the egg chamber cover frequently took place during or soon after a heavy rain.

Twins have been reported for *T. c. triunguis* (Crooks and Smith 1958) and *T. c. major* (Tucker and Funk 1976). Of 464 eggs that hatched, one egg contained twins. When the nest was opened we found one egg partly pipped. It contained both a live turtle and a dead one. The twin lived from 13 October until 22 March the following year.

Reproductive Output.—There have been conflicting reports concerning the reproductive strategy of the box turtle, many of which have been anecdotal. Iverson (1977) reported that *T. carolina* laid one clutch per year. Laying of more than one clutch per nesting season has been reported for *T. carolina* (Dickson 1953), *T. c. carolina* (Ewing 1935; Finneran 1948; Riemer 1981; Zeiller 1994), *T. c. major* (Tucker et al. 1978; Jackson 1991), and *T. c. bauri* (Dodd and Franz 1994). Ernst et al. (1994) state that two clutches per season are normal for *T. carolina* subspecies other than. *T. c. major*.

In our study the mean number of clutches per female per season was 3.31 ± 0.13 (N = 230 clutches). The mean internesting interval was 19.1 ± 0.3 days (N = 156 intervals), and the mean number of eggs per clutch was 3.40 ± 0.7 (range 1–7, N = 247 clutches; Fig. 1).

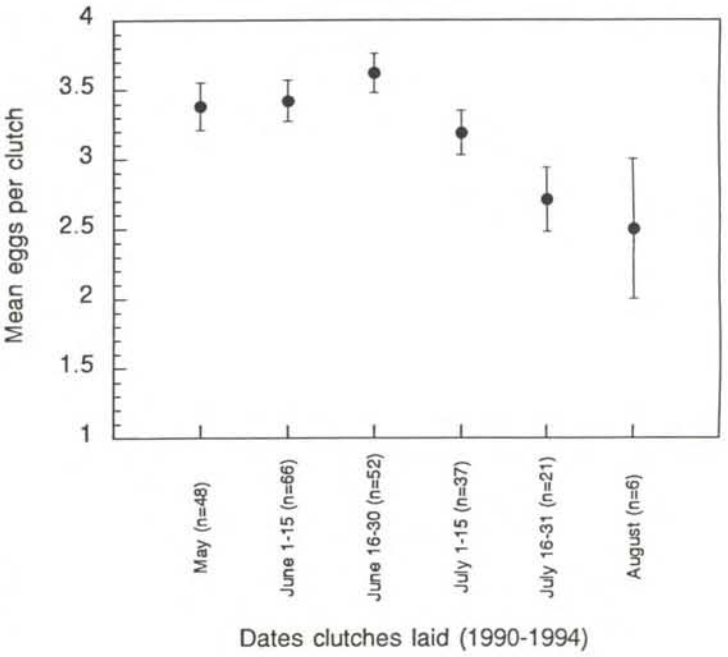

FIG. 1. The mean number of eggs per clutch varies during the nesting season. Clutch means ± 1 SE are plotted. (N) = number of clutches.

The mean weight of eggs was 9.64 ± 0.45 grams (range 8–11, N = 7). The mean egg length was 34.14 ± 0.82 mm (range 24.7–40.2, N = 21). The mean width was 20.56 ± 0.41 mm (range 17.1–24.3, N = 21). Most of the eggs measured were infertile.

The hatching success for 845 eggs was 55%. The mean weight of neonates was 7.2 ± 0.1 grams (range 4.2–9.8, N = 133). The

TABLE 2. Incubation periods and hatching success for three-toed box turtles in Louisiana varied among eggs laid during different periods in a nesting season. Mean = mean incubation period (days) ± SE. % Hatch = percent of eggs that hatched. N = number of eggs.

	Periods of Oviposition					
	May	1–15 June	16–30 June	1–15 July	16–31 July	August
Mean	91.3 ± 0.7	84.1 ± 0.6	81.4 ± 0.8	82.7 ± 0.8	78.0 ± 1.7	90.6 ± 0.2
Range	80–102	64–98	62–109	71–106	66–114	90–91
% Hatch (N)	30.6 (160)	63.4 (224)	63.8 (188)	62.8 (161)	45.7 (83)	38.5 (13)

mean neonate weight per clutch was 24.7 ± 1.4 grams (range 14.1–37.8, N = 24 clutches). These 24 clutches were laid by 16 different females.

Some females laid more clutches per season than others. Severely injured or sick turtles did not nest. The length of the nesting season, which differed from year to year, and the length of the interclutch intervals were two other factors that helped determine the number of clutches a female could lay in one season. One female twice laid 6 clutches in one season, and she and two other females laid 5 clutches in a season. The other females laid from one to four clutches in a season (Table 1).

In calculating incubation periods we considered a neonate hatched when it no longer had a visible yolk sac. We defined a nesting season as the time from the laying of the first clutch of a year through the laying of the last. All clutches were laid between 13 May and 13 August, and 71% of the clutches were laid between 1 June and 20 July.

The small size of the study area limited the variety of nesting sites and this probably influenced the length of time females searched before nesting. We attempted to protect the nests from vertebrate predators and from dehydration, and this influenced the hatching success and incubation periods.

Occasionally there were long wet periods during May. The study area was relatively flat and the soil had a high clay content. This did not promote rapid drainage and was probably an important factor in the lack of hatching success for clutches laid in May. The greater hatching success of eggs laid in June and July appeared to be due not only to the warmer weather, but also to the drier environment (Table 2).

We feel certain that confinement to the study area had no significant influence on the number of clutches laid per season, and that healthy three-toed box turtles in northeast Louisiana normally lay 3–4 clutches per nesting season.

Acknowledgments.—We would like to thank the following from Northeast Louisiana University: Perri K. Eason for her assistance and critical reviews of this manuscript; Amy G. Ouchley for her encouragement and assistance in preparing the manuscript; and Peter T. Sherman for his assistance with a graph. We would also like to thank the anonymous reviewers and Lyndon A. Mitchell for their helpful suggestions. Kenneth G. Everett of Stetson University, Michael A. Dloogatch, and Herbert S. Harris, Jr. for securing copies of relevant papers, and Frank L. Messinger for his assistance in getting our study started.

Delayed Fertilization in the Monitor Lizard *Varanus gouldii*

Delayed fertilization has been reported in a large number of squamates (Blackwell 1954; Darevsky 1971; Fitch 1970; Greer 1989; Groves 1973; Haines 1940; Joss and Minard 1985; King 1977; Philipp 1979; Wall 1905; Woodward 1933), but there has only been one suspected instance reported in varanids (Auffenburg 1981). This report describes a case of delayed fertilization in *Varanus gouldii* at the Dallas Zoo.

A pair of *V. gouldii* were observed copulating on several occasions between 2 July and 17 September 1994. On the latter date, the male was removed due to a dermal infection. Twenty-one days later, the female deposited a clutch of ten eggs. After a few weeks these eggs began to desiccate and fertility could not be determined. The same female deposited a second clutch of eight eggs 65 days after oviposition of the first clutch. After three months of incubation, a fiberoptic egg candler revealed the presence of embryos and blood vessels, confirming fertility in four of the eggs. The male had not been housed with the female after 17 September 1994. Since gestation is unknown for this species, the exact length of sperm storage cannot be determined.

Acknowledgments.—We thank J. B. Murphy, L. A. Mitchell, C. M. Garrett, D. M. Boyer, D. T. Roberts, K. A. Bradley, and A. C. Walters for helpful advice in the preparation of this manuscript.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in volume 26, number 1.

CAUDATA

AMBYSTOMA TAYLORI (Taylor's Salamander). **RECORD SIZE.** *Ambystoma taylori* is a poorly studied Mexican salamander endemic to Laguna Alchichica, one of several crater lakes (axalapazcos) in the llanos of eastern Puebla, México, located at 2345 m (97°24'00"WL, 19°24'13"NL). The maximum snout-vent length (SVL) reported for *A. taylori* is 113 mm (Brandon et al. 1981. S. California Acad. Sci. 80(3):112–125.). Herein I report a female 126 mm SVL (to the median point of the cloaca), 230 mm TL, and 76.04 g live wet weight collected 27 February 1994 at 2030 h. The specimen was found struggling in a vertical position at the surface of the lake approximately 1 m from the edge. At this point the lake is approximately 1 m in depth. The specimen (ENEPI 6035) is deposited in the herpetological collections at the Universidad Nacional Autonoma de México, Campus Iztacala. I am grateful to Julio Lemos-Espinal who read an initial draft of this note.

Submitted by **MIGUEL ANGEL SANTINELLI-RAMOS,** Fuente de Tauro #15, Lomas de Tecamachalco, Edo. de México 53950, México.

ANEIDES FERREUS (Clouded Salamander). **REPRODUCTION.** Arboreality is common among tropical plethodontid salamanders (Lynch and Wake 1976. Nat. Hist. Mus. Los Angeles Co. Sci. Bull. 25:1–65), and it is probable that many of these species nest in trees (e.g., Good and Wake 1993. Herpetol. Monogr. 6:131–159; McCranie and Wilson 1993. Herpetol. Rev. 23:115–116). However, temperate plethodontids are generally terrestrial or fossorial (but see Jaeger 1978. Copeia 4:686–691; Madigon and Shoop 1970. Science 168:1484–1487), except for some members of the genus *Aneides*. Stebbins (1951. Amphibians of Western North America. Univ. California Press, Berkeley) reported *A. lugubris* in tree cavities as high as 20 m, and also reported nesting sites in hollow trees. Van Denburgh (1916. Proc. California Acad. Sci. 4th ser. 6(7):215–221) reported *A. ferreus* 6.6 m high in a snag, and Leonard et al. (1993. Amphibians of Washington and Oregon, Seattle Audubon Society, Seattle, Washington) reported *A. ferreus* 40 m high in a snag. Dunn (1942. Copeia 1942:52), and Storm (1947. Herpetologica 4:60–62) described nests of *A. ferreus* in decaying logs; however no tree nests have been reported. During August 1988, one of us (RAW) was examining the canopy foliage of recently felled trees from a logging operation in an old-growth stand at the Yurok Experimental Forest in Del Norte Co., California, USA, for evidence of marbled murrelet (*Brachyramphus marmoratus*) nests. The forest was predominately redwood (*Sequoia sempervirens*), with western hemlock (*Tsuga heterophylla*) and Douglas-fir (*Pseudotsuga menziesii*). The trees being harvested were 70–100 m in height, with breast height diameters of 2–3 m and first limbs >20 m above ground. On a large redwood tree RAW discovered a cluster of six salamander eggs. The egg cluster had been dislodged from a fern clump (*Polypodium* spp.) that had broken open from the impact of felling. No adult salamander was observed in attendance when the cluster was discovered. The fern was at the base of a limb

"T" (Fig. 1B). After cutting, melt both ends of the woven strip and the perimeter of the mesh material with a soldering iron to prevent unraveling and to conform the mesh material to the shape of the transmitter. Harness straps are then made from strips of clear polyurethane elastic (Stretchrite™) measuring 10 cm by 0.5 cm; polyurethane elastic is thin and lightweight, and maintains elasticity at low humidity and high temperature. Fasten the straps, positioned at about 45°, to the vertical leg of the "T" with cyanoacrylic glue (Superglue™) and a stitch of thread (Fig. 1B). The backpack harness may now be affixed to the transmitter package with dental acrylic.

Position the backpack on the lizard's neck with the antenna pointing posteriorly (Figs. 1C and 1D). Pull a strap over the shoulder of one leg and through the axilla of the other leg, and fasten it to the top of the transmitter package with a drop of superglue. Fasten the second strap in the same manner, and glue the two straps together where they cross on the venter; this will keep the package from shifting (Fig. 1D). The straps must be pulled sufficiently tight so as to remain snug when the lizard deflates its body and adpresses its ribs following release. This attachment method allows the package to sit firmly on the back of the lizard and restricts movement of neither the head nor the legs.

Total mass of the telemetry backpack (< 4 g) is about 25% of the mass of the adult *P. mcallii* (mean = 15.8 g, range 11.0–25.0 g) that we fitted with transmitters; the backpack was comparable in mass to an egg clutch for this species, about 27% of total body mass (Pianka and Parker 1975). Newly captured adults were fitted with transmitters and held in captivity for 5 to 10 d to allow them to become accustomed to the backpack in the absence of predators. In captivity the lizards resumed feeding immediately after attachment of the transmitters; in the field, released lizards also resumed normal activities (eating, mating, constructing burrows, etc.). Individuals were recaptured every 2–4 months to exchange batteries and to take body measurements without the transmitter.

Forty-five individual *P. mcallii* were outfitted in this manner from April 1990 through July 1992, for a total of 7944 lizard-days and 1172 resightings. Most individuals carried their backpacks until killed by predators or until we removed the backpack at the end of the study. All lizards in the study were permanently marked with colored beads (Fisher and Muth 1989), enabling us to differentiate "escaped" from newly-captured individuals. Few individuals slipped out of their harnesses, but the backpack was shed when the straps failed in three cases. In two of these cases, the glue joint failed; a strap broke on one backpack harness. Evidence from two other losses indicates predator assistance (puncture holes and tears in straps and acrylic).

This method of attachment can be used on other species of horned lizards as well as on species with less specialized body forms.

Acknowledgments.—We thank Victor Horchar and Tracey Weiss for assistance in the field. Barbara Kermeen (AVM) took things in stride and provided technical advice when we arrived at her office with lizards in hand. The California Department of Fish and Game provided funding (FG9268) and the University of California's Boyd Deep Canyon Desert Research Center provided logistic support.

HERPETOLOGICAL HUSBANDRY

A Simple Method of Mite Control

Lizards play host to a broad range of ectoparasites. In a group of San Esteban chuckwallas *(Sauromalus varius)* located at the Arizona Sonora Desert Museum, mites of the species *Hirstiella pyriformis* and *H. trombidiformes* were found to be prevalent ectoparasites. The chuckwallas were housed indoors in 76 x 76 x 40 cm wooden cages with screen fronts and windows on the sides. An incandescent heat light and 20-watt fluorescent fixtures equipped with both blacklight and Chroma 50 (GE) tubes were attached to the ceilings of the cages. Mites and their egg sacs were commonly found in the corners of the cages, adjacent to and under light fixtures, along the crevices created by the closed cage doors, and external to the cages along the stand/cage juncture as well as on the lizards. These mites migrate to lay their eggs and then to search for a host.

Historically mites have been battled on two fronts: eradication of mites on the lizard and in the cage. Topical application of such chemicals as Dri-Die (Farkas 1993; Loomis 1985), Wermectin (Farkas 1993), and alcohol require handling and restraint of the animal as well as careful application to avoid such delicate tissues as eyes and mucous membranes. Ivermectin, which may be topically applied or injected (Abrahams 1992; Nathan 1994), raises the additional risks of needle damage and improper dosages. All of these chemicals may be injurious or cause death to the animal if used improperly (Farkas 1993; Loomis 1985; Nathan 1994).

Mite control in cages is often attempted by the application of dilute bleach solutions (Nathan 1994), trichlorfon (Boyer and Boyer 1991), or Wermectin (Farkas 1993) sprays. These methods require removal of the animal and careful husbandry lest the animal, its food, or water come into contact with any of the residual chemicals. Vapona (Loomis 1985) and No-pest (Farkas 1993; Nathan 1994) strips have been placed in cages with the animals; the strips must be encapsuled to prevent animal contact and the water bowl must be removed (Farkas 1993; Loomis 1985; Nathan 1994).

With such stipulations regarding the current methods of mite control, new methods which neither require veterinary prescriptions, husbandry changes or large budgets, nor present acute toxic reactions or latent poisoning situations, need to be considered. I have developed a technique for physical removal of mites and their eggs which avoids these problems.

One-inch wide strips of masking tape were applied to the internal and external walls of the cages, usually at a horizontal orientation. Tape locations included adjacent to cage windows, doors, and along the upper cage walls and ceiling junctions out of reach of the lizards. Only the center of the tape was fixed to the cage.

This was accomplished by running a sharp object down the center of the strip, thereby leaving the edges unattached. Mites crawl up under the tape and are trapped by adhesion. Many egg sacs have also been found under the tape. The tape is changed weekly due to saturation by the mites.

Though mite prevention through proper cleaning, sterilization, and quarantine is preferable to any control method, once infestation has occured additional measures must be taken. The masking tape trap method for mite control, when used in conjunction with other proven methods, may be a beneficial tool for maintaing a healthy collection.

Early Breeding in a Captive Corn Snake (*Elaphe guttata guttata*)

The pairing of a normal female and an anerythristic male corn snake, *Elaphe guttata guttata*, (both captive hatched on 13 September 1989), resulted in a clutch of ten eggs laid on 18 May 1991. Seven of the eggs in this clutch hatched between the period 29 July and 4 August 1991. A female (hatched 4 August 1991) and a male from the same clutch were subsequently housed together in a terrarium providing a temperature gradient of approximately 15–32°C. No copulation was observed, but between 15 and 26 May 1992 the female laid five eggs. Due to an acute decline in health, the female was euthanized on 29 June 1992, and a necropsy revealed an additional retained egg in the oviduct. At the time of sacrifice the female (AMB 3379, Villanova University) measured 60 cm SVL + 8 cm tail length. Two of the eggs laid in May were viable and after incubation at room temperatures (maximum 26°C) hatched on 12 and 13 August 1992.

The age at first reproduction in *E. g. guttata* is typically reported to be approximately two years (McEachern 1991; Rossi 1992). However, early breeding can occur in captives of many snake species, and reproduction in corn snakes can occur at less than one year (McEachern 1991). Documented cases of breeding before about the age of 18 months, however, are very rare. Bechtel and Bechtel (1958) reported that maturity was reached in their captive female corn snakes at about 18 months and a total length of 21–29 inches (53–74 cm). Golder (1981) reported more rapid maturation under constant controlled conditions, with oviposition by second captive generation females at an age of one year and five days and a total length of 71 cm. Pre-oviposition gestation in captive *E. guttata* has been variously reported to last from 35–37 days (Holman 1960; MacMahon 1957) to 54–68 days (Bechtel and Bechtel 1958). Assuming even the shortest period of gestation, the female that laid eggs on 12 May 1992 at an age of nine months, eleven days, would have had to mate at an age of approximately eight months. This is three months earlier than the snake reported by Golder (1981), assuming similar gestation periods, and appears to be the earliest documented successful mating by a corn snake.

Although eight months is certainly precocious, the size of the animal at the time of mating was probably only slightly less than at death (68 cm total length), reasonably close to the 75 cm minimum size for reproduction suggested by McEachern (1991), and greater than the 53 cm minimum reported by Bechtel and Bechtel (1958). This confirms the primacy of body size over chronological age in predicting sexual maturation in captive snakes.

In this instance, the very early mating of sibling corn snakes was inadvertent; the animals were maintained together on the assumption that they were too young to mate. Nonetheless, this successful reproductive event highlights potential dangers of early matings in captive snakes. Young females of relatively small size may suffer greatly from the dehydration and weight loss that accompany oviposition (McEachern 1991), may have a greater tendency to become egg-bound, or may suffer unforeseen future reproductive problems (Rossi 1992).

Acknowledgments.—We thank Charlie Klauder for the (accidental) breeding loan of AMB 3379.

CAUDATA

AMBYSTOMA TIGRINUM TIGRINUM. (Eastern Tiger Salamander). **REPRODUCTION** and **TWINNING.** Very few data have been recorded on the occurrence of twins in *Ambystoma tigrinum tigrinum*. Here I describe an occurrence of eggs with twin embryos and their hatching in a sample of *A. t . tigrinum* eggs collected on Long Island, New York, USA, from 1987–1993.

During repatriation of this New York State endangered species to one of its historic localities on Long Island, egg masses were transferred from six Long Island donor ponds to three ponds on the former Hudson Estate (Bishop 1941, Salamanders of New York State, New York State Mus. Bull. 324:155–173). Data were recorded on the number of eggs per clutch, and notes were taken on embryo development in the field and in aquaria.

In 1987 and 1988, three eggs with twin embryos were found (two in 1987 and one in 1988); all were from one of the donor ponds in Ridge, Suffolk County, New York (NYS Department of Environmental Conservation Endangered Species Unit site S-15). No further occurrences of twin salamanders have been observed in the total sample of 7846 eggs since 1988.

The question arises whether the eggs with twin embryos were deposited by the same female. Unfortunately this could not be determined. All three of the eggs with twins had developed into twin embryos prior to being collected from the donor pond. In each instance, the egg with twins was placed in a separate aquarium to monitor its development. The aquaria contained other loose *A. t. tigrinum* eggs in pond water from the donor pond, which was gradually replaced with pond water from the eventual release site.

While the eggs with twins were in the aquarium, data were recorded on egg and embryo dimensions and development. All measurements were taken through the aquarium glass after gently moving the egg against the glass. The diameter of the normal eggs and eggs with twins all varied from 8–10 mm.

In all cases, the twin embryos were noticeably smaller than those of single-embryo eggs. At the time of hatching, the twin embryos were 11 mm total length, whereas single embryos were 14 mm total length.

The hatching process was observed for two of the three cases of twins. After the first embryo emerged, the capsule apparently resealed, or allowed so little leakage, that the second embryo could delay its emergence. In the two observed hatchings, the delay of emergence between the first and second embryos was 12 h in the first case and 16 h in the second.

Despite the smaller size of the twin larvae, all six twin hatchlings were equally as vigorous as other newly-hatched *A. t. tigrinum* larvae. All six twins survived and were released.

I wish to thank the New York State Department of Environmental Conservation, Division of Fish and Wildlife, Endangered Species Unit and N.Y.S. D.E.C. Region 1 for their cooperation and support during this project. In particular, I would like to thank Alvin Breisch and Michael Kallaji of the Endangered Species Unit, Michael Scheibel of Region 1 D.E.C., and Norman Soule of the Cold Spring Harbor Fish Hatchery and Aquarium, for their advice and help throughout the project. I am also grateful to Alvin Breisch of the N.Y.S. D.E.C. Endangered Species Unit and Herbert C. Mills of the Nassau County Museum, for reviewing the first draft of this note.

Submitted by **ALLAN J. LINDBERG**, Nassau County Museum, 45 Sandy Hill Road, Oyster Bay Cove, New York 11771, USA.

PSEUDOEURYCEA BELLI BELLI (NCN). **PREDATION.** In July 1994, while collecting reptiles in a pine-oak forest, a *Pseudoeurycea b. belli* (MZFC-6841, 69 mm SVL, sex unknown) was regurgitated by a *Rhadinaea t. taeniata* (MZFC-6803, 485 mm SVL) at El Tapeixtle, near El Terrero, Municipality of Minatitlán, Colima, México, elevation 2310 m. The salamander's tail was broken, but the body was intact. According to Myers (1974. Bull. Amer. Mus. Nat. Hist. 153(1):220), *Pseudoeurycea b. belli* has not been recorded previously as prey for *Rhadinaea t. taeniata.* The only other prey item recorded for *R. t. taeniata* is *Anolis* sp. This record increases the number of species of *Rhadinaea* that feed on plethodontid salamanders to 11 (see Myers 1974, *op. cit.*; Mendoza-Quijano and Rendon-Rojas 1995, Herpetol. Rev. 26:40).

We thank Claudio Mendoza Paz, Mario Mancilla, and Alfonso Delgadillo for help in the field. Financial assistance was provided by the Dirección General de Asuntos del Personal Académico (DGAPA) proyecto INZ01789 and NSF.INT 60091.

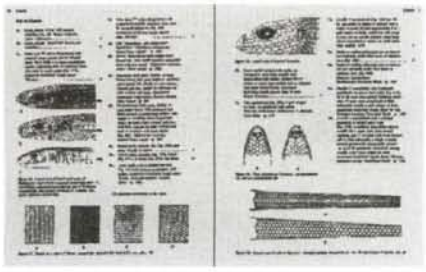
ANURA

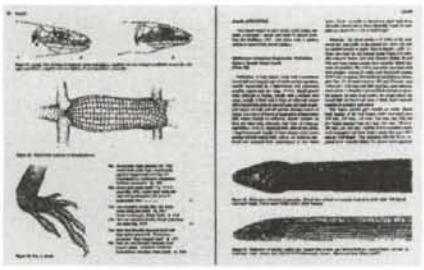
BUFO WOODHOUSII (Woodhouse's Toad). **FECUNDITY.** Anurans are noted for their ability to produce extremely large clutches. Probably the largest reported clutch is one laid by a female *Rana catesbeiana* that contained 47,840 eggs (McAuliffe 1978. Nebraska Game and Parks Report, Lincoln). North American bufonids are also noted for laying extremely large clutches. For example, 45,054 eggs for *Bufo cognatus* (Krupa 1994. J. Herpetol. 28:217–224), ca. 26,000 eggs for *B. exsul*, and ca. 18,000 eggs for *B. canorus* (Kagarise Sherman 1980. Ph.D. dissertation, Univ. Michigan, Ann Arbor), and 13,452 eggs for *B. americanus* (Kruse 1981. Herpetologica 37:228–233). To the best of my knowledge, Smith (1934. Amer. Midl. Nat., 15:377–528) reported the largest clutch for *B. woodhousii* at 25,644 eggs. Below, I report on a larger clutch for this species.

At sunset, shortly after a heavy rain on 28 May 1987, a 101 mm SVL female *B. woodhousii* was found paired to a 74 mm SVL male in a temporary pool in Norman, Cleveland Co., Oklahoma. The female had not yet begun to oviposit. The pair was gently transferred to a water-filled wading pool at the University of Oklahoma's Animal Behavior Facility. The pair remained together during the night and the female began ovipositing after midnight and was finished by 0600 h the next morning. At this time the pair was released and the eggs were preserved in a 5% formalin solution. Later, the eggs were spread out in a grid-marked pan and counted using a tally counter. The preserved clutch is currently housed at the University of Kentucky's School of Biological Sciences.

The clutch contained 28,493 eggs, which is probably the largest clutch reported for this species. However, it is likely that larger clutches are produced by this species. I have observed egg masses



REPTILES
OF NORTH CAROLINA



WILLIAM M. PALMER & ALVIN L. BRASWELL
ILLUSTRATIONS BY RENALDO KUHLER

Filled with superb drawings & color plates, this is the definitive work on the 71 reptile species that occur in the state.

"Palmer and Braswell, it seems, left no stone or log unturned in North Carolina to amass the amount of information contained in this exemplary work."
—Robert H. Mount, Auburn University

"[This book] is well written, well organized, and scientifically sound, and it contains some of the most beautiful—and accurate—pen-and-ink drawings I have ever seen in a work of this nature. It is a book that is going to prove useful to both professional and amateur herpetologists, and to naturalists in general."
—Douglas A. Rossman, Curator of Reptiles, Louisiana State University Museum of Natural Science

laid by a single female *B. woodhousii* that covered a greater area than did 40,000 to 45,000-egg clutches laid by *B. cognatus* (Krupa 1994. J. Herpetol. 28:217–224). Thus, counting additional clutches will most likely reveal that *B. woodhousii* is capable of producing much larger clutches than reported here.

Submitted by **JAMES J. KRUPA**, School of Biological Sciences, University of Kentucky, Lexington, Kentucky 40506-0225, USA.

ISCHNOCNEMA QUIXENSIS (NCN). **VOCALIZATION.** The telmatobiine leptodactylid frog *Ischnocnema quixensis* is a terrestrial inhabitant of the upper Amazon Basin in southern Colombia, Ecuador, Peru, and western Brazil. Although this species is relatively abundant within its range, nearly nothing is known about its ecology (Duellman 1978. Misc. Publ. Mus. Nat. Hist. Univ. Kansas 65:1–352). Its reproductive biology is completely unknown.

During October to December 1988 at Panguana, Río Lluapichis, Amazonian Perú (9°35'S, 74°56'W, elev. ca. 250 m; see map in Toft and Duellman 1979. Herpetologica 35:71–77) we recorded two different calls of a male *I. quixensis*. Recordings were made on TDK cassette tape using a SONY-D6C tape recorder (4.8 cm/sec) and a Sennheiser microphone ME 88. Analysis were made with a Kay DSP Sonagraph 5500. Sound pressure levels were measured using an impulse sound level meter (CEL-214; flat-weighted, fast RMS mode) at a distance of 1 m from the calling male.

Male *I. quixensis* mainly call at night with a peak at sunset (1800–2000 h). The recorded male was interacting with another male 3.5 m distant. There were two types of sound signals, which occured either alone or in combination.

Call Type I (Fig. 1): Although there were no observations on female phonotaxis, we interpret this sound as an advertisement call (sensu Wells 1977. Anim. Behav. 25:666–693). It is a loud single "fueet," consisting of clear harmonics with a fundamental frequency between 1300 and 3400 Hz. The frequency range attends from 1250 to 5600 Hz. Dominant frequency is at 2560 Hz with secondary maxima at 1.6 kHz, 1.9 kHz, and 5.1 kHz. Call duration is about 310 ms.

Call Type II (Fig. 2) is a very low, snarling sound, which can sometimes be heard directly before an advertisement call. Its frequency range attends from 500 Hz to 3600 Hz. Dominant frequency is at 1500 Hz and call duration is about 200 ms.

Sound pressure level of call type I (N = 8) was 85 ± 1 dB. Call type II is audible only for a very short distance. Peak levels of this call type were not measured.

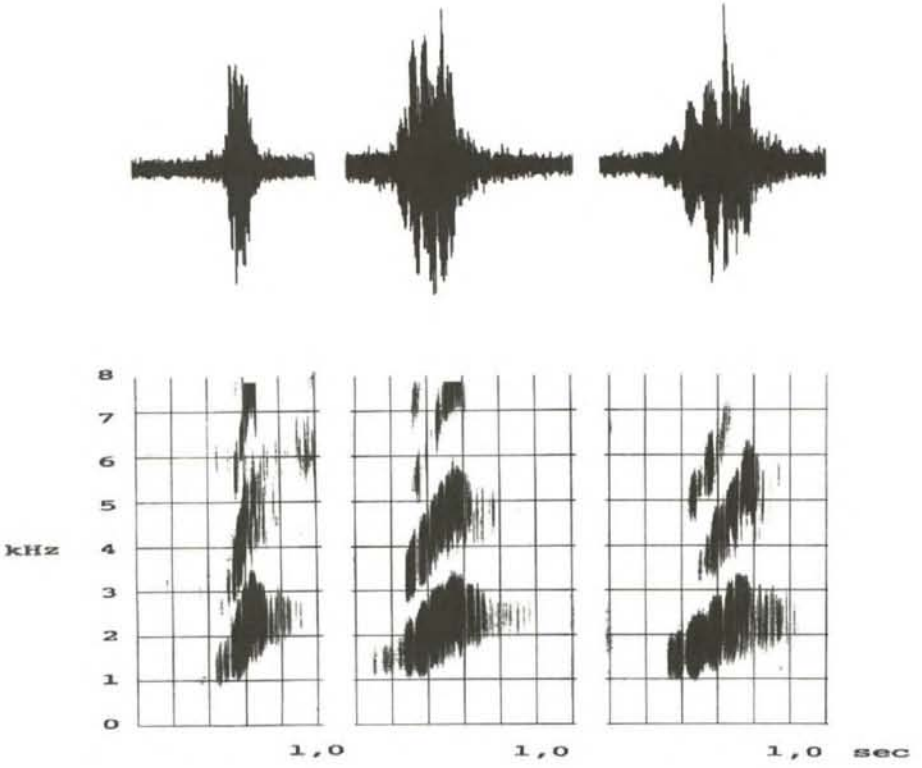

FIG. 1. Oscillograms (upper) and sonograms (lower) of advertisement calls (call type I) of *Ischnocnema quixensis*. Air temperature 27°C.

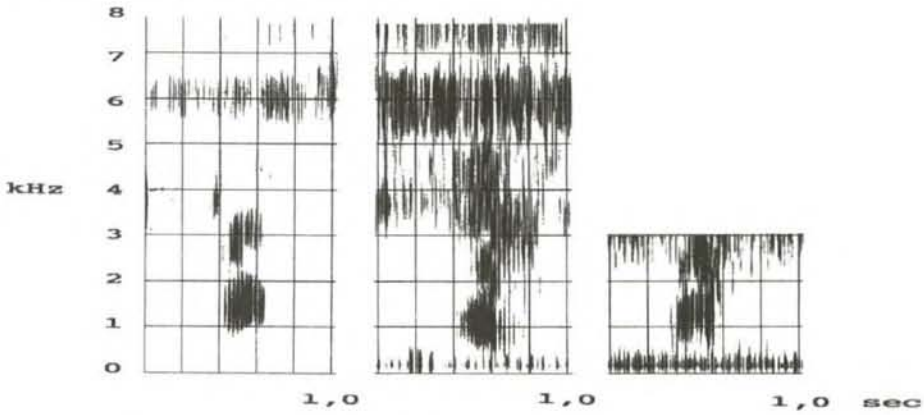

FIG. 2. Sonograms of call type II of *Ischnocnema quixensis*. Air temperature 27°C.

We thank Hans-Wilhelm Koepcke for providing the possibility to continue investigations of anuran ecology at Panguana. We are grateful to Walter Hödl for directing us in measurements of sound levels, and to Richard A. Seigel for helpful comments on our manuscript. Ing. José Purisaca, Ministerio de Agricultura, Lima, and Nelly Carrillo de Espinoza, Museo de Historia Natural, Lima, generously cooperated. Fieldwork was supported by the Deutsche Forschungsgemeinschaft, Bonn.

Submitted by **ANDREAS SCHLÜTER**, Staatliches Museum für Naturkunde, Schloss Rosenstein, Rosenstein 1, D-70191 Stuttgart, Germany, and **JAVIER ICOCHEA**, Museo de Historia Natural, Universidad Nacional Mayor de San Marcos, Av. Arenales 1256, Apartado 14-0434, Lima 14, Peru.

Note added in proof: The report by Heyer and Cascon (1995. J. Herpetol. 29:304–307), concerning call characteristics of Brazilian *Ischnocnema quixensis*, appeared too recently to be considered in this report.

LACERTILIA

GERRHONOTUS OPHIURUS (NCN). **CLUTCH SIZE** and **MATERNAL CARE.** Here we present observations on clutch size and maternal care in *Gerrhonotus ophiurus*, a species distributed in southern San Luis Potosí, northern Hidalgo and Puebla, and northern and central Veracruz, México (Tihen 1948. Trans. Kansas Acad. Sci. 51(3):302–305; Smith and Taylor 1950. Bull. U.S. Nat. Mus. 199:1–253; Taylor 1953. Kansas Univ. Sci. Bull. 35(13):1587–1614; Good 1994. Herp. Monogr. 8:180–202). On 26 May 1992 we collected an adult female *G. ophiurus* (WSB-012, SVL = 128 mm, TL = 495 mm) at Xilitilla, km 259 on Mx. Hwy. 120, Municipality of Xilitla, San Luis Potosí. The elevation of the site is 740 m and the vegetation is tropical deciduous forest. The specimen was collected with a clutch of 10 eggs. The eggs varied in length and width from 20 x 12 to 20 x 15 mm (N = 9; mean = 20 x 13.5 mm; SD = 0.00 and 3.27 for length and width), and in mass from 2.5 to 3.39 (N = 9; mean = 3.09; SD = 0.81). The mass of the clutch, excluding one egg which was desiccated and not measured, was 27 g. These egg sizes are larger than those reported by Flury (1949. Herpetologica 5:65–67) for a clutch of 10 eggs of *G. liocephalis infemalis* (= *G. infernalis*).

At the time of collecting, the female did not attempt to escape and only moved her head as though searching for refuge or protection, much as noted by Greer (1967. Herpetologica 23:94–99) for a male *Diploglossus delasagra* presumably guarding eggs. The female was coiled around the clutch as described for other species of anguids (Somma 1990. Smithsonian Herpetol. Infor. Serv. 81:1–53.). Gibbons (1977. Misc. Publ. Mus. Zool. Univ. Michigan 154:1–55.) mentioned that *G. liocephalus* probably removed spoiled eggs from the nest (see also Greene and Dial 1966. Herpetologica 22:303; Fitch 1970. Univ. Kansas Misc. Pub. Nat. Hist. 52:111). We found a dry egg in the clutch which had not been removed, nor did we see signs of oophagy.

Greene and Dial (*op. cit.*) concluded that *Gerrhonotus* spp. care for their eggs, and our observations support their conclusion, because only 27 days elapsed until the eggs hatched. Presumably the female had guarded her nest for at least half of the developmental period of 42–46 days (Flury, *op. cit.*).

On 21 June 1992, all nine eggs hatched in the laboratory. The hatchlings ranged in SVL from 33–40 mm (mean = 38.3 mm), tail length from 64–75 mm (mean = 70.8 mm), and total length from 97–115 mm (mean = 109.2 mm). Hatchling color varied; three individuals showed reddish coloration and the other six were yellowish. Flury (*op. cit.*) described similar color variation for *G. liocephalis infernalis* (= *G. infernalis)* from Texas.

We thank J. W. Sites, O. Flores-Villela, H. M. Smith, and L. A. Fitzgerald for comments on drafts of this manuscript. FMQ is grateful for financial support from the Direccion General de Apoyo Personal Academico (DGAPA) project IN201789.

PHRYNOSOMA CORONATUM BLAINVILLII (San Diego Horned Lizard). **GROWTH**. *Phrynosoma coronatum blainvillii* were marked and released from April 1990 to October 1991 on two study sites in southern California. The first study site was located at TlS, R3W, S10 (SW 1/4) in the City of Redlands, San Bernardino Co., and the second at T4S, R4W, S24 (SW 1/4) on the University of California's Motte Rimrock Reserve, City of Perris, Riverside County. A total of eight individuals (four adults and four hatchlings) were recaptured for growth rate analysis; juveniles were not included because of a recapture rate of zero. Mean daily growth between recaptures was calculated for each individual then averaged for hatchlings and adults. All lizards were measured to the nearest 1 mm. Lizards >75 mm SVL were considered adults, those between 75 mm and 50 mm were considered juveniles, and lizards <50 mm, hatchlings.

Hatching of horned lizards occurred during a short period from late July to early August. Hatchlings ranged from 27–31 mm SVL and may have been several days old at the time of measurement. One male hatchling was recaptured twice with an increase of 0.345 and 0.200 mm/day at 13 and 15 days between measurements, respectively. Another male was recaptured once (16 days between measurements) and grew 0.375 mm/day. Two females were recaptured once, each at 13 day intervals between measurements, with one growing 0.077 mm/day and the other 0.154 mm/day. Overall mean growth of hatchlings was 0.230 mm/day (SD = 0.127; N = 5). One hatchling measured 47 mm SVL on 1 October 1990 before its first hibernation.

Juvenile growth was not calculated because no individuals were recaptured. Two juveniles, however, were captured following what was thought to be their first hibernation: a male measuring 50 mm SVL was captured in February 1991 and a female measured 66 mm SVL in May 1990.

Mean growth for adult horned lizards was 0.105 mm/day (SD = 0.165; N = 8). One male was recaptured once at 32 days between recaptures and grew 0.125 mm/day. Two other males were recaptured twice; one of these males grew 0.493 and 0.054 mm/day at 345 and 74 days, respectively, between measurements, and the other was recaptured at 230 and 55 days between measurements with no growth and growth of 0.127 mm/day, respectively. One female was recaptured three times during the study at 68, 324, and 49 days between measurements with growth (0.040 mm/day) detected only at the first recapture.

I thank B. H. Brattstrom for his many discussions of the natural history of the San Diego horned lizard as well as his review of this manuscript. The California Department of Fish and Game kindly provided a Memorandum of Understanding (issued to BHB) to conduct research on *P. c. blainvillii*.

Submitted by **STEPHEN B. HAGER**, Department of Biological Science, California State University, Fullerton, Fullerton, California 92634, USA. Present Address: Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003-0001, USA.

SCELOPORUS CHANEYI (NCN). **REPRODUCTION** and **FEEDING**. On 20 July 1992 we collected 13 adult specimens of *Sceloporus chaneyi* in a rocky *Agave* grassland and open pine forest area approximately 18 km NE San Antonio Peña Nevada, Nuevo Leon, México (23°49'N, 99°52'W). As this species belongs to the *S. scalaris* species group, which contain both oviparous and viviparous species (Sites et al. 1992. Bull. Am. Mus. Nat. Hist. 213:1–110), and the parity mode of this species was not known at the time of its description (Liner and Dixon 1992. Texas J. Sci. 44:421–427), we here report that this species is oviparous. This conclusion is based on the presence of five well-developed, shelled eggs (mean length 10.2 x 6.5 mm; SD = 0.37 x 0.30 mm; range 9.6 x 60 to 10.5 x 6.9 mm) in a gravid female (MZFC 54732, 44.6 mm SVL, 100.2 mm TL, 4.2 g). The rest of the females showed previtellogenic and vitellogenic follicles.

One of us (MEMS) examined the stomach contents of eleven of these specimens (MZFC 5473(6); BYU 45364–45365, 45393, 45399–45400). Except for a small quantity of vegetative material (1.3 % of total mass), stomach contents were composed entirely of insect remains, representing the orders Coleoptera, Diptera, Hemiptera, Homoptera, Hymenoptera, Lepidoptera, and Orthoptera. Hymenopteran remains appeared most frequently (90 out of 125 identifiable remains, with 84 of the 90 belonging to the family Formicidae), though the greatest percent of the mass was from Coleopteran remains (41.6 %), followed by Lepidoptera (31.5 %).

We thank Wesley M. Brown for reviewing this note. This work was funded by a grant (NSF-INT DEB911909) to Jack Sites, Jr. and to Direccion General de Apoyo al Personal Academico (DGAPA; project IN201789).

Submitted by **DANIEL G. MINK**, Department of Biology, University of Michigan, Ann Arbor, Michigan 48109, USA; **MARIA ELA MARTINEZ SOLIS** and **FERNANDO MENDOZA QUIJANO**, Museo de Zoologia, Facultad de Ciencias, UNAM, Apdo. Post. 70-399, D.F. 04510, México.

VARANUS PANOPTES (NCN) and ***VARANUS GOULDII*** (Sand Goanna). **DIET** and **PREDATION.** As part of a study of field metabolic rates, a number of *Varanus panoptes* and *V. gouldii* were captured, injected with isotopes, fitted with a radio transmitter and released on 9 September 1990 in Kakadu National Park, Northern Territory, Australia (12°38'S, 132°22'E). The location of the lizards was periodically checked for the next three weeks when they were to be recaptured for a blood sample. One small *V. gouldii* (mass = 370 g; the maximum mass measured for this species in this area was slightly over 2 kg) moved only a short distance during this period. This species is inactive during the dry season, and they are known to spend most of their time underground between June and October (unpubl. data). The *V. gouldii* entered a new burrow on 25 September, and it blocked the entrance of the burrow from the inside with soil; this behavior was also practiced by other individuals of this species in the dry season. The signal from the radio transmitter indicated that the lizard was approximately 1.5 m from the plugged entrance of the burrow. I routinely placed small twigs over the entrances of burrows to determine if a lizard exited between inspections of the site. This lizard remained in the burrow for 5 days. On the fifth day I visited the site and found a large *V. panoptes* standing approximately 10 m from the burrow, and the transmitter signal was being emitted from that point. The *V. panoptes* was noosed, and when the lizard opened its mouth in a threat display I saw the tip of the smaller goanna's tail. Because I wanted to recover the radio transmitter and a blood sample from the *V. gouldii*, I gently pulled the tail until I had recovered the *V. gouldii* from the *V. panoptes*.

The *V. panoptes* was weighed (3.35 kg) and released unharmed. This species can attain a mass of 7 kg in this area (unpubl. data). The *V. gouldii* represented a meal of 11% the mass of the *V. panoptes*. The dead goanna had a small external wound on the neck, but the neck also appeared to be broken. One foot was missing, and most of the muscle on that leg was stripped away. Otherwise the animal was intact.

Interestingly, inspection of the burrow revealed that, rather than opening the plugged entrance, the *V. panoptes* had dug a hole straight down at the point 1.5 m from the entrance where I had located the transmitter signal on the previous day. This fact, along with the observation that the *V. gouldii* had not left the burrow for 5 days, suggests that *V. panoptes* have keen senses—presumably chemoreception (Losos and Greene 1988. Biol. J. Linn. Soc. 35:379–407), but possibly also hearing—for the capture of prey.

Stomach analyses of varanid lizards have shown that a variety of lizards, including other varanids, are included in the diet (James et al. 1992. J. Herpetol. 26:128–136; King and Green 1979. Copeia 1979:64–70; Losos and Greene, *op. cit.*; Pianka 1970. West. Aust. Nat. 11:141–144; Pianka 1982. West. Aust. Nat. 15:1–8; Shine 1986. Herpetologica 42:346–360). In this case, previous knowledge of the individual prey animal and its burrow suggest that varanids have a formidable ability to detect and subdue their prey.

Submitted by **KEITH A. CHRISTIAN**, School of Biological Sciences, Northern Territory University, P.O. Box 40146, Casuarina, Northern Territory 0811, Australia.

SERPENTES

BOTHROPS ASPER (Nauyaca). **CANNIBALISM.** Intraspecific ophiophagy has been documented in a number of viperids (see Mitchell 1986. Cannibalism in Reptiles: A Worldwide Review. SSAR Herpetol. Circ. 15, 37 pp. for a review). In addition to several species of the genus *Bothrops* listed by Mitchell (*op. cit.*), cannibalism has been observed in *Bothrops asper.* Tryon (1985. Herpetol. Rev. 16:28) described this behavior in a neonate *B. asper* at the Knoxville Zoological Park. The following account is meant to supplement Tryon's (1985) observations by providing corroborative evidence from the field for *B. asper.*

During the course of a radiotelemetry study of *B. asper* in the Los Tuxtlas region of Veracruz, México (Buttenhoff and Vogt, unpubl. data), several juveniles of the species (N = 7, 500–700 mm TL) were examined for stomach contents and internal parasites. One specimen (female, 560 mm SVL) examined on 26 June 1993 contained two prey items. The first item ingested was a male rat, *Rattus rattus* (135 mm SVL), and the second prey item was a female *B. asper* (346 mm SVL). Both were ingested head first

and were in the early stages of digestion indicating that they had been consumed within a relatively short interval of each other. The cannibal had been killed upon collection in the field and there was no possibility that the ophiophagy occurred during postcapture handling. To our knowledge, this is the first field report of intraspecific ophiophagy for this species.

Young *B. asper* are known to consume a variety of prey including frogs (Solorzano and Cedras 1989. Herpetologica 45:444–450), lizards (Buttenhoff and Vogt, unpubl. data), small mammals, and invertebrates (Greene 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 107–117. Selva Press, Tyler, Texas). As *B. asper* mature, an ontogenetic shift to larger mammalian prey occurs (H. Greene and D. Hardy, pers. comm.; PB and RCV, pers. obs.) and it is unlikely that cannibalistic behavior continues. Conversely, *Bothriechis schlegelii*, a species in which adults prey on frogs, lizards, and birds, in addition to small mammals, intraspecific ophiophagy has been observed in adults (Bridegam et al. 1990. Herpetol. Rev. 21:54–55).

Little is known concerning the significance of ophiophagy (inter- and intraspecific) in the Viperidae. Martins and Gordo (1993. Herpetol. Rev. 24:151–152) observed ophiophagy in young *Bothrops atrox* in Brazil and reported that snakes (not conspecifics) composed 7% of the total prey items in the specimens examined. It is possible that similar behavior exists in other taxa.

If cannibalism is common in some species, there may be selective pressures on conspecific avoidance. Avoidance of conspecific chemical cues, for example, has been documented in prairie rattlesnakes, *Crotalus virdis*, by King et al. (1983. J. Herpetol. 17:196–198). It is possible that species with ophiophagus tendencies may use pheromonal cues as a means of avoiding conspecifics and perhaps litter or clutchmates. Avoiding areas where conspecifics are present would reduce the threat of cannibalism; thus, cannibalism could influence conspecific distribution within a given microhabitat. Natural history data for many species of viperids, however, are scarce, and only when more detailed natural history information becomes available will a clearer picture of cannibalism, and its proximate and ultimate components, emerge.

We thank George Folkerts, Craig Guyer, and Mary Mendonça for making comments that improved the manuscript.

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellow-bellied Racer). **NESTING**. While drift-fence trapping for turtles on 11 June 1994 in the Nebraska Sandhills along the northwest shore of Gimlet Lake on the Crescent Lake National Wildlife Refuge, Garden County, Nebraska (Iverson 1991. Herpetologica 47:371–393), a heavily gravid female eastern yellow-bellied racer (93.0 cm SVL; 28.5 cm tail length; 425 g) was captured along the lake side of the fence. Because she was egg-laden and leaving the meadow, we force-fed her a 12 g radiotransmitter package (LF1-STL-803, L. L. Electronics, Mahomet, Illinois 61853, USA) and released her at 1400 h RMDT across the fence to follow her to her nest site. By 2000 h she had moved 261 m northwest (325°) into the sandhills and was underground in an abandoned rodent burrow. At 1230 h the next day she was active near that burrow but was disturbed by us; by 2000 h she was in the same burrow system. The next day (13 June) at 2000 h she was in another abandoned rodent burrow in open grasslands 357 m farther north (356°) into the hills (ca. 30 m elevation above the original meadow). Some time during the next 16 h she deposited 31 eggs (mean size 29.62 x 18.78 mm, 6.17 g; clutch mass 45% of gravid body mass and ca. 77% of post-gravid body mass). The eggs were in loose, fine sand in that burrow, which was on a southwest facing hill (214°) with a ca 15° slope. Depth to the top of the eggs was 14.1 cm and to the bottom of the eggs, 18.4 cm.

At 1200 h 14 June she was active at a location 26 m southwest (233°) of the burrow where she nested. When next located (0600 h the next morning), she had moved approximately 350 m and was inactive in the same burrow system she had occupied on 12 June. By 1430 h that day (15 June) she had returned to Gimlet Lake (including crossing our drift fence) and was about 80 m out into the flooded cattail marsh at the lake's edge. At 1800 h she was located 62 m north (342°) of the lake, buried in the very warm, loose sand piled in front of a kangaroo rat burrow complex. She was then dug up for measuring and for regurgitation of the transmitter, and found to contain a fresh 50 g (55 cm total length) plains garter snake (*Thamnophis radix*) in her stomach. Including her meal and the transmitter, she weighed 322 g.

In summary, this female left what was apparently her normal home range in a meadow near the lake, migrated over 600 m up into the sandhills in 2.5 days, deposited her eggs, returned in 24 h to the lake to hunt successfully for a meal, and then retreated to one of the warmest microclimates available, apparently to facilitate digestion of that meal. Her clutch size matches the record known for the species, but clutch sizes in this population are typically higher than in other populations of this subspecies (compare Fitch 1985. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 76:33). For comparison, snout-vent length, gravid body mass, clutch size, mean egg length, width, and mass, clutch mass as a percent of gravid body mass, and clutch mass as a percent of post-gravid body mass for three other Gimlet Lake racers captured in June 1993 and held until oviposition were 78 cm, 202 g, 18, 28.67 mm, 17.32 mm, 5.15 g, 46%, 85%; 86, 236, 16, 31.90, 18.66, 6.71, 43%, 74.5%; and 101, 245, 21, 25.51, 16.80, 4.70, 40%, 67%, respectively.

The only other study of nesting movements of racers (Brown and Parker 1976, Copeia 1976:234) was done in Utah on *Coluber constrictor mormon* and revealed that two of four gravid females made similar long movements associated with nesting.

Submitted by **JOHN B. IVERSON, HEATHER HIGGINS, ABBY G. SIRULNIK**, and **CAMERON A. YOUNG**, Department of Biology, Earlham College, Richmond, Indiana 47374, USA.

COLUBER CONSTRICTOR (Blue Racer), ***ELAPHE VULPINA*** (Eastern Fox Snake) and ***CHELYDRA SERPENTINA*** (Snapping Turtle). **REPRODUCTION.** Intraspecific communal nesting behavior has been reported in snakes such as *Demansia psammophis, Diadophis punctatus, Opheodrys vernalis, Elaphe obsoleta, Elaphe vulpina, Coluber constrictor, Masticophis taeniatus*, and *Opheodrys aestivus* (Cook 1965. Herpetologica 20:206; Cavacevich and Limpus 1972. Herpetologica 28:208–210; Foley 1971. Herpetol. Rev. 3:41; Lawson 1983. Herpetol. Rev. 14:20; Parker and Brown 1972. Copeia 1972:892–895; Swain and Smith 1978. Herpetologica 34:175–177; Palmer and Braswell 1976. J Herpetol. 10:257–259). Occasionally, communal egg laying sites in which more than one species has laid eggs have also been reported (Brodie et al. 1969. Herpetologica 25:223–227), but these are not as common. There are no records of shared nest sites of snakes and turtles.

An investigation of nest sites of racers (*Coluber constrictor foxii*) on Pelee Island, Lake Erie, Ontario, Canada, revealed a communal nest site shared by an eastern fox snake (*Elaphe vulpina gloydi*) and a blue racer (*Coluber constrictor foxii*). A snapping turtle (*Chelydra serpentina*) nest was also found only 1.3 m from the snakes' nest. All three nests were found in a large (DBH 110 cm) decaying log lying on a beach. The log was roughly 3 m from the edge of an eastern cottonwood (*Populus deltoides*) grove and approximately 10 m from the Lake Erie beach. There was an opening (80 cm long by 10 cm high) on the east side of the log which led into a cavity lined with rotting wood and sand that had filtered into the cavity.

On 6 July 1994, a large (SVL = 1400 mm) female blue racer was located via radiotelemetry inside the decaying log, approximately 1.5 m southwest of the eastern entrance. She remained there for one day and it was assumed that she was ovipositing. After the racer left the site, we did not search for eggs because of the importance and scarcity of nesting sites.

On 7 August 1994, on a subsequent check of the log, we found four intact fox snake eggs and small pieces of others, just inside a hole that appeared to have been excavated by a predator. This hole was on the west side of the log exactly where the female blue racer was located one month earlier. The four eggs were adherent and only the middle one was free of parasitic insect larvae. Two additional viable eggs were recovered from the inner tree cavity, which was very narrow. The three viable *E. vulpina* eggs were incubated at 27°C and hatched 18–21 August 1994 (neonate SVLs = 254 mm, 213 mm and 236 mm).

On 2 and 3 September 1994, we found two neonate blue racers hiding under loose pieces of the decaying log very close to the fox snake nest. The next day, 4 September, a snapping turtle nest was located in the same rotting log, 1.3 m north of the snake nest sites. Judging by the large excavated hole leading into the nest cavity, we suspect the predator was a raccoon (*Procyon lotor*) or a grey fox (*Urocyon cinereoargenteus*). In total, remnants of 20 destroyed eggs and two partially consumed late-stage embryos were collected. The turtle clutch was slightly separated from the other clutches in the log, and it was obvious that the turtle excavated her nest, whereas the snakes laid their eggs inside the log cavity. The fact that all three clutches were laid in the same log suggests that optimal egg laying sites may not be abundant.

Much of Pelee Island is farmland (>70%) and there are many summer homes on the shoreline habitat. Normally, shoreline habitats undergo gradual erosion, which continually downs trees and provides microhabitats for ovipositional sites. However, as the natural shoreline becomes altered for human use, the number of available nesting sites for reptiles decreases. For this reason, we conclude that communal egg laying among snakes may become more common and that turtles may be forced to nest in close proximity to snake nests.

Communal nesting may reduce overall reproductive success in our population even though the sites may have optimal physical characteristics. There are two possible reasons for reduced success. First, racers, especially neonates, are cannibalistic (Liner 1949. Copeia 3:230; Fitch 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:351–468; Jackson 1971. J Herpetol. 5(3–4):196); pers. obs.). A larger number of eggs laid at a given site increases the opportunity for neonate-neonate predation. If neonate-neonate predation is a factor in the survival of aggregations of newly hatched young, then communal nesting among racers and other snakes may not optimize survival of young. Second, large aggregations of eggs may also increase the attraction of the nest to predators because of the increased odors and other cues left by the nesting adults and by the eggs. For these reasons, we suggest that separate nest sites would maximize survival of neonates. This, of course, can only be possible if alternative nest sites, each with optimum conditions (temperature, humidity and protection), are available.

Oviparity is one of the life-history traits that renders a snake species most susceptible to extirpation, and island species are more prone to extinction (Dodd 1993, *In* R. A. Seigel and J. T. Collins, eds., Snakes Ecology and Behavior, pp. 363–393. McGraw-Hill, New York). Understanding the nesting behavior and ecology of oviparous reptiles is crucial for their conservation because they are so dependent on the external environment for the successful rearing of young. Experiments designed to compare recruitment rates of neonates when nest sites are scarce vs. abundant, particularly in relation to the effects of communal nesting, would provide important information for the conservation of these island populations of oviparous reptiles.

We thank Ian Fisher and Colleen Soulliere for field assistance. Our work was funded by the Ontario Ministry of Natural Resources, Carolinian Canada, and the Endangered Species Recovery Fund of WWF, Canada.

LAMPROPELTIS TRIANGULUM SMITHI. (Smith's Milk Snake). **PREY**. An adult male *Lampropeltis tnangulum smithi,* SVL = 815 mm, TL = 969 mm (MZFC 0484), was found dead on Mexican Highway 105 México-Tampico, Zacualtipán, Hidalgo, México, elevation 2100 m (no date), in pine-oak forest. This snake contained two female *Sorex saussurei* (Hall 1981. The Mammals of North America. Vol. 1, 2nd ed. John Wiley & Sons, Inc.). Measurements of the shrews were: MZFC 5420, 91 mm total length, 36 mm tail length, 5.4 mm skull length; and MZFC 5421, 89 mm total length, and 35 mm tail length. The skull of MZFC 5421 was crushed, while MZFC 5420 was intact.

The stomach contents of other *L. t. smithi* were empty (MZFC 030, 05024, 05026). The ingestion of shrews as food in *L. tnangulum* apparently is rare as Williams (1988. Systematics and Natural History of the American Milk Snake *Lampropeltis tnangulum.* Second ed. Milwaukee Public Mus. 176 pp.) registered this type of prey only for *L. t. tnangulum* (*Blarina brevicauda*) and for *L. t. abnorma* (*Cryptotis noitai*). These records are the first reports of food habits of this subspecies.

We thank H. M. Smith and L. A. Fitzgerald for comments on this manuscript and D. G. Mink for the translation into English. Logistic support was provided by the Direccion General de Apoyo al Personal Academico (DGAPA) project IN201789.

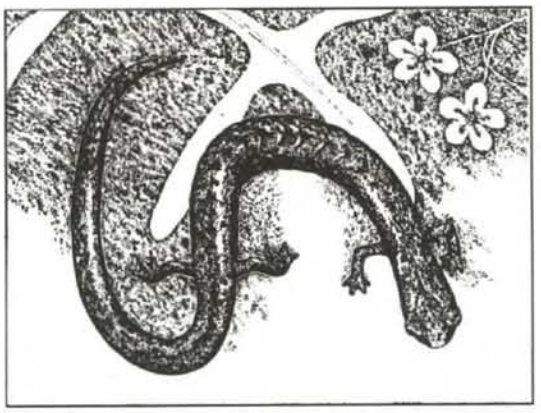
Submitted by **FERNANDO MENDOZA QUIJANO** and **HUGO A. RUIZ PINA**, Museo de Zoologia, Facultad de Ciencias, UNAM. Apdo. Post. 70-399, D.F. 04510, México.

NERODIA TAXISPILOTA (Brown Water Snake). **DIET.** *Nerodia taxispilota* feed almost exclusively on fish, primarily catfish (Ictaluridae) (Camp et al. 1980. J. Herpetol. 14:301–304; Ernst and Barbour 1989. Snakes of Eastern North America. George Mason Univ. Press, Fairfax, Virginia, 282 pp.). Food items were collected as part of a long-term study on the natural history of *N. taxispilota* in the Savannah River adjacent to the Savannah River Site (SRS), Aiken and Barnwell counties, South Carolina, and Burke Co., Georgia (for exact location, see Gibbons and Semlitsch 1991. Guide to the Reptiles and Amphibians of the Savannah River Site. Univ. of Georgia Press, Athens, 131 pp.). Here we report two genera of fishes (*Lepisosteus* and *Morone*) not previously reported in the diet of *N. taxispilota*. On 18 June 1993 we captured a male snake (53 cm SVL) that was forced to regurgitate a partially digested gar (*Lepisosteus*; 14.2 cm standard length; 27% of the SVL of the snake). We also identified five fish of the family Moronidae (formerly Percichthyidae: temperate bass) from five snakes (date collected, sex, SVL in cm): 26 August 1991, F, 39.7; 30 August 1991, F, 40.8;13 August 1992, F, 36.0;18 August 1992, M, 34.5; 26 August 1992, M, 34.9. Two species of gar (*Lepisosteus osseus* and *L. platyrhincus*) and two species of temperate bass (*Morone saxatilis* and *M. chrysops*) inhabit the Savannah River near the SRS, but *L. platyrhincus* and *M. chrysops* are rare in this area (Bennett and McFarlane 1983. The Fishes of the Savannah River Plant: National Environmental Research Park. Savannah River Ecol. Lab., Nat. Environ. Res. Park Program, U.S. Dept. Energy, SRO-NERP-12, 152 pp.). These records are of interest because *N. taxispilota* typically feed on bottom-dwelling fishes while striped bass and gar are mid-to top-water flshes.

We thank J. W. Gibbons and J. A. Weis for reviewing the manuscript. This research was supported by contract DE-AC0976SR00-819 between the U.S. Department of Energy and the University of Georgia's Savannah River Ecology Laboratory.

Submitted by **MARK S. MILLS** and **CHRIS J. HUDSON**, Department of Zoology, University of Georgia, Athens, Georgia 30602, USA, and Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA.

OPHRYACUS UNDULATUS (Mexican Pit Viper). **LITTER SIZE.** Little is known about the reproductive habits of *Ophryacus undulatus* (Fitch 1970. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52:1–247; Murphy and Mitchell 1984. Acta Zool. Path. Antverp. 78:199–214). Murphy and Mitchell reported litter sizes of 6, 8, 3, and 7 from four wild-caught females collected near Omiltemi, Guerrero, México. Additionally, Flores-Villela (*pers. comm.*) observed the birth in captivity of 8 young from a female obtained near Omiltemi on 25 February 1986.



On 17 September 1990 a female *O. undulatus* from 5 km NW of Tenango de Doria, Hidalgo, México gave birth to 13 young. One was born dead and no infertile ova were found. The female (MZFC 4828) measured 600 mm SVL and 667.5 mm TL. The neonates are dark brown dorsally, except for one which is grayish, with darker brown transverse spots. Ventrally they are grayish with yellow fringes, the subcaudal surface is gray. This coloration differs from that of the juveniles of Omiltemi population (Murphy and Mitchell, *op. cit.*; Munoz-Alonso 1988. Tesis Biol. Fac. Ciencias, UNAM, 102 pp.) which exhibit scattered black dots over the entire venter; the dorsal color is smoky-gray to brownish green, with darker zig-zag stripes.

The mean size at birth of the 12 live neonates was 168 mm SVL (range = 162–177 mm, SD = 4.2 mm) and 193 mm TL (range = 187–202 mm, SD = 3.4 mm); their mean mass was 4.34 g, (range = 3.98–4.73 g, SD = 0.23 g).

This litter exceeds by 5 the maximum reported for this species, although the mean TL of the Tenango de Doria litter was considerably less than the mean TLs of the Omiltemi litters (mean TLs: 226, 234, 246, and 233; Murphy and Mitchell *op. cit.* and mean TL = 209 mm for the litter observed by Flores-Villela).

We thank Amaya Gonzalez for help in the laboratory, Oscar Flores-Villela for counsel, and H. M. Smith and Lee A. Fitzgerald for comments on the ms. FMQ acknowledges financial aid for this project through DGAPA project IN201789.

SLENDER SALAMANDER POSTCARDS

A set of four cards (approx. 5 1/2" x 4 1/8"), each of a species of *Batrachoseps* endemic to the mountains of southern California - elegant, eye-catching, pen & ink sketches to add distinction to your correspondence. Tehachapi, Relictual, Kern Canyon, and Kern Plateau slenders are depicted. $2.50/set of 4 (add 16 cents/set sales tax for orders within California).
Order from Tim Manolis, 808 El Encino Way, Sacramento, CA 95864.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 26, Number 1.

AMPHIUMA MEANS (Two-toed Amphiuma). USA: LOUISIANA: Tangipahoa Parish: Two adult males (> 33 cm total length) were captured in a roadside ditch along Highway 1064, near Milton Rd., 5 km west of Natalbany. 13 May 1995. Verified by Brian Crother. Second and third parish records; extend range 23 km S and 40 km W of known distribution (Dundee and Rossman 1989, Amphibians and reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.; Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin, Boston, Massachussetts. 450 pp.). Of 38 *Amphiuma* captured in four nights following heavy rain, 36 were *A. tridactylum* and two were *A. means*.

Submitted by **J. SEAN DOODY**, **DON R. CHURCH**, **RICHARD E. ANDERSON**, **ARMIN R. MEIER**, and **PAT J. CONNOLLY**, Department of Biological Sciences, Southeastern Louisiana University, Box 814, Hammond, Louisiana, 70402, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: MINNESOTA: Itasca Co: Chippewa National Forest, Suomi Hills Semi-Primitive Area, 47°26'N, 93°39'W. 22 August 1994. Bell Museum of Natural History, University of Minnesota (MMNH 13472). Captured in drift fence/pitfall array operated by the Minnesota County Biological Survey (Minnesota Department of Natural Resources) and the Chippewa National Forest. Verified by John J. Moriarty. New state record; extends range ca. 115 km northwest of nearest known locality in Bayfield County, Wisconsin (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus. 205 pp.)

Submitted by **CAROL J. DORFF**, Minnesota County Biological Survey, Department of Natural Resources, 500 Lafayette Road, St. Paul, Minnesota 55155, USA.

PLETHODON LARSELLI (Larch Mountain Salamander). USA: WASHINGTON: Kittitas Co: NW 1/4 of NE 1/4 Sec. 14, T22N, R12E, Box Canyon, Wenatchee National Forest, 1200 m elev. 16 June 1994. Patricia A. Garvey-Darda. Verified by Kelly McAllister and William P. Leonard. Central Washington University Herpetology Collection (CWU 281, juvenile). A mature adult (CWU 282) was collected from the same locality 2 July 1994. New county record; extends the northern range for this species by a distance of approximately 95 km (Washington Department of Wildlife 1993, Status of the Larch Mountain salamander in Washington. Unpubl. Rep. Washington. Dept. Wildl., Olympia) and is the first recorded occurrence of this species or any member of the family Plethodontidae east of the Cascade crest in the state of Washington (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow, 332 pp.).

Submitted by **DAVID M. DARDA**, Department of Biological Sciences, Central Washington University, Ellensburg, Washington, 98926, USA, and **PATRICIA A. GARVEY-DARDA**, Cle Elum Ranger District, Wenatchee National Forest, Cle Elum, Washington, 98922, USA.

SIREN INTERMEDIA INTERMEDIA (Eastern Lesser Siren). USA: VIRGINIA: Caroline Co: Fort A. P. Hill Military Reservation, Turkey Track Creek at Thornton Road, ca. 6 km NW Bowling Green. 29 March–1 April 1994. Robert S. Hogan and Steven M. Roble. Virginia Museum of Natural History (VMNH 6761–6763). Verified by Dirk J. Stevenson. Specimens were captured in unbaited minnow traps. New county record and northern range limit (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed.

Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). Only previously published records for Virginia are from Southampton County and the City of Suffolk (Padgett and Lane 1986, Herpetol. Rev. 17:49; Pague and Mitchell 1987, Virginia J. Sci. 38:304–318). Extends range limit of the species ca. 175 km NNW from the Southampton County site.

Submitted by **STEVEN M. ROBLE**, Division of Natural Heritage, Virginia Department of Conservation and Recreation, 1500 East Main Street, Suite 312, Richmond, Virginia 23219, USA.

phological and biochemical data show all three vouchers are hybrids of *B. punctatus* x *B. boreas*. Specimens of putative nonhybrids of both *B. punctatus* and *B. boreas* were later located at this locality on 24 May 1993; vouchers of *B. boreas* were collected (temporarily deposited at the Biological Sciences Department, California State Polytechnic University, Pomona) but permission to collect additional *B. punctatus* was denied by the Reserve Board of Directors; however, photographs were taken to confirm presence.

Submitted by **MICHAEL M. FULLER**, Department of Zoology, University of Oklahoma, Norman, Oklahoma, 73019-0235, USA.

BUFO PUNCTATUS (Red-spotted Toad). USA: TEXAS: Potter Co: 11.3 km W Amarillo, Tascosa Road. 1972. W. Bens. WTAMU 1994. Verified by Anthony I. Mazeroll. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 434 pp.).

First county records (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 434 pp.) and a western range extension of about 40 km at the extreme southern tip of Texas.

Submitted by **KATHLEEN B. BLAIR** and **FLAVIUS C. KILLEBREW**, Department of Biology and Geosciences, West Texas A&M University, Canyon, Texas 79015-0808, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

HYLA CADAVERINA (California Chorus Frog). USA: CALIFORNIA: Riverside Co: Temecula Gorge along the Santa Margarita Ecological Reserve. Lacy L. Grismer, Michael T. Hainline, Jr., and Jesse L. Grismer. Verified by L. Lee Grismer. La Sierra University Herpetological Collection (LSUHC 3000–02). On 30 April 1995, one male was heard calling at 1100 h but was not located. Several individuals were observed later that night between 1900 and 2030 h. Additional males were observed calling within the boundaries of the Santa Margarita Ecological Reserve approzimately 0.5 km to the west. All males were calling from rocks at the water's edge. Lee et al. (1973, Center Reg. Environ. Stud.) conducted a seven month herpetological survey along the Temecula Gorge within the Santa Margarita Ecological Reserve and reported that the occurence of this species was probable but not verified. Verification of this species within the Temecula Gorge and the Santa Margarita Ecological Reserve is important in that this taxon can now be incorporated into the reserve's future management plans.

Submitted by **JESSIE L. GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA, **MICHAEL T. HAINLINE, JR.**, 1298 Burris, EL Cajon, California 92021, USA, and **LACY L. GRISMER**, 28920 Vallejo Avenue, Temecula, California 92592, USA.

HYLA CINEREA (Green Treefrog). USA: TEXAS: Aransas Co: Fulton. 16 April 1992. J. Culwell. WTAMU 14473. 1.2 km N Aransas National Wildlife Refuge. 4 March 1978. Keith Meador. WTAMU 5293. 0.9 km N Aransas National Wildlife Refuge. 20 April 1990. D. Stanford. WTAMU 14029. Verified by Anthony I. Mazeroll. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 434 pp.).

Submitted by **KATHLEEN B. BLAIR** and **FLAVIUS C. KILLEBREW**, Department of Biology and Geosciences, West TexasA&M University, Canyon, Texas 79015-0808, USA, and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

MELANOPHRYNISCUS RUBRIVENTRIS (NCN). BOLIVIA: COCHABAMBA: López Mendoza, 2780 m. 15 February 1990. Jaime Bosch and Ignacio De la Riva. Verified by William E. Duellman. MNK AM 923. First record for the country. Occurrence of this species in Bolivia is not surprising because there are records in northern Argentina very close to the Bolivian border (see Etzel 1988, D. Aquar. Z. Stuttgart 41:348–350). However, it was unexpected to find it at such high elevation. Other species

such as *Bufo arenarum* and *Odontophrynus americanus* show a similar distributional pattern; they occur in dry forests of northwestern Argentina and enter the Bolivian Eastern Cordillera through dry valleys to the Cochabamba region. This record extends the known distribution of *M. rubriventris* more than 500 km north.

Submitted by **IGNACIO DE LA RIVA**, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA.

WHAT'S HERPETOZOA ?

HERPETOZOA is a journal devoted to all aspects of herpetology published by the Austrian Society for Herpetology (Österreichische Gesellschaft für Herpetologie - ÖGH). ÖGH membership includes the price of subscription to **HERPETOZOA** (192 pages p. a.).
HERPETOZOA contains original articles, review papers, short notes and book reviews in German or English.
HERPETOZOA is cited in the Zoological Record.

Advisory Editorial Board: E.N. Arnold (London), O.J. Arribas (Soria), W. Böhme (Bonn), A.Cabela (Wien), B.P. Chondropoulos (Patra), I. Darevsky (St. Petersburg), A. Dubois (Paris), G. Fachbach (Graz), G. Gollmann (Wien), B. Grillitsch (Wien), K. Grossenbacher (Bern), R. Günther (Berlin), M.S. Hoogmoed (Leiden), L. Luiselli (Roma), W. Mayer (Wien), G. Nilson (Göteborg), F.J. Obst (Dresden), N.N. Szczerbak (Kiev), H. Tunner (Wien).

Address to be contacted for authors and future members:
Österreichische Gesellschaft für Herpetologie, c/o Naturhistorisches Museum, Burgring 7, A-1014 Wien.
Membership fee per annum: US$ 35.-.

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: COLORADO: Lincoln Co: Marlin Mason Ranch, 1 km N Lincoln-Crowley county line, 1.3 km E Rt. 71. 31 May 1995. Marlin Mason. Verified by Richard L. Holland. UCM photographs 98–99. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, 131 pp.).

Submitted by **BETH DE SANTIS, BRANDON SHEAFOR** and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA, and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA.

CHRYSEMYS PICTA BELLII (Western Painted Turtle). USA: COLORADO: Crowley Co: pond at jct. Road BB and Rt. 71. 29 May 1995. H. M. Smith. Verified by Richard L. Holland. UCM 57335. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, 131 pp.).

Submitted by **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder Colorado 80309-0218, USA.

SAURIA

CNEMIDOPHORUS INORNATUS INORNATUS (Little Striped Whiptail). MÉXICO: NUEVO LEON: 3.5 mi (5.6 km) W Aramberri, 4700 ft. (1433 m). 20 July 1975. Ernest A. Liner, Richard M. Johnson, and Allan H. Chaney. TCWC 51816–24 (formerly EAL 4058). Verified by James R. Dixon. Wright and Lowe [1993. J. Arizona-Nevada Acad. Sci. 27(1):129–157] mapped the

various subspecies, and showed no records for this area, which is located ca. 80 mi (129) km to the SE of their mapped distribution.

Submitted by **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA, and **ALLAN H. CHANEY**, Department of Biology, Texas A&M University at Kingsville, Texas 78363, USA.

CNEMIDOPHORUS INORNATUS PAULULUS (Mexican Little Striped Whiptail). MÉXICO: NUEVO LEON: 4.5 mi (7.2 km) N Mier y Noriega at Rancho San Roberto, 6800 ft. (2073 m). 20 July 1974. Ernest A. Liner, Richard M. Johnson, and Allan H. Chaney. EAL 3828. Verified by James R. Dixon. Wright and Lowe [1993. J. Arizona-Nevada Acad. Sci. 27(1):129–157] mapped the various subspecies, and showed no records for Nuevo Leon; this record is ca. 70 mi (112.6 km) to the NE in the extreme southern part of the state, and ca. 46.6 mi (75 km) to the SW of the southern record of *Cnemidophorus i. inornatus*.

Submitted by **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA, and **ALLAN H. CHANEY**, Department of Biology, Texas A&M University at Kingsville, Kingsville, Texas 78363, USA.

CNEMIDOPHORUS INORNATUS PAULULUS (Mexican Little Striped Whiptail). MÉXICO: SAN LUIS POTOSÍ: 9.2 mi (14.8 km) E Santo Domingo at La Presca de Guadalupe on México 80, 3900 ft. (1189 m). 18 July 1976. Ernest A. Liner, Richard M. Johnson, and Allan H. Chaney. EAL 4205 (3 specimens). Verified by James R. Dixon. Wright and Lowe's [1993. J. Arizona-Nevada Acad. Sci. 27(1):129–157] map of the subspecies is ca. 70 mi (112.6 km) to the W of this record.

Submitted by **ALLAN H. CHANEY**, Department of Biology, Texas A&M University at Kingsville, Kingsville Texas 78363, USA, and **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA.

ELGARIA KINGII (Madrean Alligator Lizard). USA: NEW MEXICO: Doña Ana Co: 17 km S Hatch in Choases Canyon, Sierra de Las Uva. May 1994. Donovan Wagner. Verified by Paul W. Hyder. NMSU 6952. First record for the Sierra de Las Uvas (Stebbins 1985, A Field Guide To Western Reptiles and Amphibians, Houghton Mifflin Co., Boston, Massachusetts. 336 pp.) and the third for Doña Ana County (Knight and Duerre 1987, Southwest. Nat. 32:283–285).

Submitted by **DONOVAN WAGNER** and **JAVIER F. GURROLA**, Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003-30001, USA.

EUMECES LATICEPS (Broadhead Skink). USA: LOUISIANA: Evangeline Parish: 2.4 km W jct. Rt. 29 & Rt. 104 on Bayou des Cannes, 30°37'58"N, 92°18'48"W. 16 April 1995. A. E. Landreneau. Verified by James E. Cordes. University of Arkansas Department of Zoology Museum (UADZ 5451–52). New parish record and range extension. An indeterminate record already exists for the boundary between Evangeline and Rapides Parishes in the vicinity of Cocodrie Lake (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rogue. 300 pp.). Our record verifies the parish occurrence of this species, filling the hiatus between Rapides, St. Laundry, and Acadia Parishes, and extends the range to southern Evangeline Parish.

Submitted by **HARLAND D. GUILLORY** and **AMY E. LANDRENEAU**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: LOUISIANA: St. Landry Parish: 3.5 km E jct. US Rt. 190 & Rt.13, 30°29'37"N, 92°22'42"W. 5 May 1995. R. P. Hatler. Verified by James E. Cordes. University of Arkansas Department of Zoology Museum (UADZ 5453). New parish record (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **MALCOLM F. VIDRINE** and **RYAN P. HATLER**, Division of Sciences, Louisiana State Unversity at Eunice, Eunice, Louisiana 70535, USA.

HOMONOTA BORELLI (Neotropical Gecko). ARGENTINA: SALTA: Ciudad (24°47'S, 65°25'W). 12 June 1994. E. Richard. Fundación Miguel Lillo (FML 3180). Verified by Raymond F. Laurent. Species was first recorded from Salta province by Peracca (1897, Boll. Mus. Zool. Anat. Com., Univ. Torino, 12(274):1–19) but Cei (1993. Mus. Reg. di Sci. Nat. Torino, Monog. XIV:952 pp. inter alli) gave no precise records for this province. Another paper (Cruz et al. 1992. Acta Zool. lilloana, 42(1):101–107) indicated this species as occurring in Anta Department. Our records confirm Salta Ciudad as the type locality for this species.

Submitted by **ENRIQUE RICHARD** and **VIRGINIA ABDALA**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 - Tucumán, República Argentina.

PODARCIS ERHARDII (Erhard's Wall Lizard). GREECE: Pori and Lagouvardos islets south of Peloponnese (35°58'E, 23°14'N and 35°58'E, 23°12'N, respectively). 20 January 1992. E. D. Valakos, P. Maragou, and M. Mylonas. Verified by B. Chondropoulos. Museum of Natural History, University of Crete, Greece, MNHUC E1–E15 (Pori) and MNHUC E43–E44 (Lagouvardos). First records of the species for both islands. Although the commonest lizard in the Aegean, this species is absent from the surrounding areas of South Peloponnese and the neighboring bigger islands of Kithira and Antikithira (Gruber 1986, Handbuch der Reptilien und Amphibien Europas, W. Boehme (ed.), AULA-Verlag Wiebaden).

Submitted by **EFSTRATIOS D. VALAKOS** and **PANAGIOTA MARAGOU**, Department of Biology, Section Ecology and Taxonomy, University of Athens, GR-157 71 Panepistimioupolis, Athens, Greece, and **MOYSIS MYLONAS**, Department of Biology, P. O. Box 1470, University of Crete, GR-711 10 Iraklio, Greece.

SCELOPORUS SCALARIS (Bunch Grass Lizard). USA: ARIZONA: Cochise Co: Coronado National Forest, Whetstone Mountains, French Joe Canyon, ca. 5450 ft (1660 m) elev., SW 1/4 Sec. 3, T19S, R19E. 14 April 1995. J. M. Howland and J. M. Whittinghill-Howland. Adult male. Verified by Jack W. Sites, Jr. BYU 45508. Only specimen known from Whetstone Mountains; partially fills gap in known range between nearest records—17 km W Empire Valley, ca. 20 km S Babocomari Valley, and ca. 38 km E Dragoon Mountains.

Submitted by **JEFFERY M. HOWLAND**, Nongame Branch, Arizone Game and Fish Department, 2221 West Greenway Road, Phoenix, Arizona 85023, USA, and **JAN M. WHITTINGHILL-HOWLAND**, 4925 West Grandview Road, Glendale, Arizona 85306, USA.

SCELOPORUS SMITHI (Smith's Rosebelly Lizard). MÉXICO: CHIAPAS: Municipality of Arriaga, 2 km SW of Arriaga (latter town 16°13'51"N, 93°52'53"W), 150 m elev. 1 August 1993. Fernando Mendoza and Alfonzo Delgadillo. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México

(MZFC 5965, two females, 51 and 40 mm SVL respectively). Verified by Adrian Nieto Montes de Oca. Found on large granite boulders in the same habitat that other populations occupy in coastal Oaxaca. First record for the state; an apparent confirmation of the presence of this taxon ESE of Tapanatepec, Oaxaca, where Smith et al. [1993 Bull. Maryland Herp. Soc. 29(3):94] reported a possible hybrid between *S. smithi* and *S. v. variabilis*, although the specimen was referred to the latter taxon. The present specimen agrees in most repects with the characteristic scalation, coloration, and pattern of *S. smithi*.

Submitted by **FERNANDO MENDOZA QUIJANO, MA. ELA MARTINEZ SOLIS**, Museo de Zoología, Universidad Nacional Autónoma de México, Apartado Postal 70-399, México, Distrito Federal 04510, México, and **HOBART M. SMITH**, Department of Environmental, Populational, and Organismic Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

SERPENTES

AFRONATRIX ANOSCOPUS (African Brown Water Snake). SENEGAL: SENEGAL ORIENTAL REGION: Bandafassi (12°32'N, 12°18W). 15 February 1994. Yero Keita. Verified by Ivan Ineich. Museum National d'Histoire Naturelle at Paris (MNHN 1995.4173). First record for Senegal; extends to the NW the previous known range (Guinea to Cameroun) (Villiers 1975, Les Serpents de l'Ouest Africain. Institut Fondamental d'Afrique Noire, Initiations et Etudes Africaines, n°2. 3e edition. Dakar. 195 pp).

Submitted by **JEAN-FRANCOIS TRAPE** and **YOUSSOUPH MANE**, Laboratoire de Paludologie, ORSTOM, P. O. Box 1386, Dakar, Sénégal.

BOTHROPS LEUCURUS (White-tailed Lancehead). BRAZIL: ALAGOAS: Usina Seresta, São Miguel dos Campos (9°47'S, 36°05'W). 10 April 1984. Décio Morais. MNRJ 3978; BAHIA: Fazenda Mata Nova, 8 km south to São Roque do Pataguaçu (12°51'S, 38°51'W). 15 June 1991. Valéria P. Firme. MNRJ 4445; CEARA: Floresta Nacional do Araripe, Crato (7°14'S, 39°23'W). 27 January 1990. MNRJ 3942. February 1990. MNRJ 3943. Both collected by Dante Teixeira; SERGIPE: Fazenda Capivara, Brejo Grande (10°26'S, 36°28'W). 25 May 1991. Carlos Caetano. MNRJ 4443–4444. All verified by Ulisses Carasmachi, Museu Nacional do Rio de Janeiro (MNRJ). *Bothrops leucurus* is known only from Salvador (type-locality) and Feira de Santana, Bahia, in northeastern Brazil. In addition, there is an unsubstantiated record from Sergipe (Campbell and Lamar 1989, The Venomous Reptiles of Latin America. Cornell Univ. Press, New York. 425 pp.). These records confirm the presence of this species in Sergipe and add it to the states of Alagoas and Ceará.

Submitted by **MARCOVAN PORTO**, Departamento do Zoologia, Instituto de Biociências, Universidade de São Paulo, P. O. Box 11294, Brazil, Brazil CEP: 051422-970, and **DANTE MARTINS TEIXEIRA**, Departmento de Vertebrados, Museu Nacional/UFRJ, Rio de Janeiro, Brazil, Brazil CEP: 20940-040.

COLUBER CONSTRICTOR MORMON (Western Yellowbelly Racer). USA: COLORADO: La Plata Co: near Bondad. 5 May 1984. Sonya Webb. Verified by Richard L. Holland. UCM 57327. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, 131 pp.); major range extension of some 150 km southward into the upper San Juan River drainage, not far from New Mexico.

Submitted by **PRESTON H. SOMERS**, Department of Biology, Fort Lewis College, Durango, Colorado 80301, USA, **LAUREN J. LIVO**, 1215 South Osceola, Denver, Colorado 80219, USA, **REBBECA R. J. SMITH**, 2632 Taft Street, Lakewood, Colorado 80215, USA, and **DAVID CHISZAR** and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

CROTALUS VIRIDIS (Western Rattlesnake). USA: COLORADO: Dolores Co: vicinity of Cahone/Dove Creek landfill, M road, 1.6 km E jct. Rt. 666, 6.4 km S Dove Creek. About 1991. Colleen Quinn. Verified by Richard L. Holland. UCM 57326 (rattle only). First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, 131 pp.).

Submitted by **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA; **LAUREN J. LIVO**, 1215 South Osceola, Denver, Colorado 80219, USA; **REBECCA R. J. SMITH**, 2632 Taft Street, Denver, Colorado 80215, USA; and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

GRAYIA THOLLONI (Thollon's Water Snake). SENEGAL: SINE-SALOUM: Keur Bakar Mané, banks of Djikoye Stream (13°38'N, 16°16'W). 7 September 1990. Babacar N'Dao. Verified by Ivan Ineich. Museum National d'Histoire Naturelle at Paris (MNHN 1995.4172). First record for Senegal. In West Africa, this species was known only from a single specimen from The Gambia, Kotu stream, S of Bathurst, and from a series of specimens from Nigeria (Hughes 1983, Bonn. Zool. Beitr. 34:311–356; Dunger 1972, Nigerian Field 37:21–38). This second specimen from the westernmost part of Africa confirms its presence and extends its range some 3000 km further W than previously known. Djikoye Stream is situated 46 km NE of Kotu Stream; they are separated by the mouth of The Gambia River, which is saline for more than 150 km inland, and by the mangrove swamps associated with this river and its tributaries.

Submitted by **JEAN-FRANCOIS TRAPE** and **YOUSSOUPH MANE**, Laboratoire de Paludologie, ORSTOM, P. O. Box 1386, Dakar, Sénégal.

LEPTOPHIS MEXICANUS SEPTENTRIONALIS (Tamaulipan Parrot Snake). MÉXICO: SAN LUIS POTOSÍ: Municipality of Cuidad Valles, Gustavo Garmedia (15 km N Ciudad Valles). 25 October 1992. Walter Schmidt B. Verified by F. Mendoza-Quijano. Museo de Zoologia, Facultad de Ciencias, UNAM (MZFC-05396). Juvenile specimen; agrees with subspecific characters given in a key by Henderson [1976, J. Herpetol. 10(4):329–331]. First State record and second for the subspecies; extends range 114 km airline from the closest known locality at Tampico, Tamaulipas, although some museum specimens reported for this state as *L. m. mexicanus* before the description of this subspecies by Mertens (1972 Senckenbergiana Biol. 53(5–6):341–341) might be *L. m. septentrionalis*.

Submitted by **MARIO MANCILLA MORENO** and **WALTER SCHMIDT BALLARDO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, México, Distrito Federal 04510, México.

NAJA KAOUTHIA (Monocled Cobra). THAILAND: LOEI PROVINCE: Amphoe Phu Rua, 2 km from the village Ban Na No and 5 km from the Phu Luang Wildlife Research Center, 700 m elev. 4 September 1992. Tany Chan-ard. Verified by Wolfgang

Wuster. Thailand National Research Council, Bangkok (TNRC 52-3886). New record for Loei Province (Taylor 1965, Univ. Kansas Sci. Bull. Vol. 45, No. 9, p. 949).

Submitted by **MEREL J. COX**, 695/17 Pracharaj Road, Soi Pracharaj 19, Bangsue, Bangkok 10800, Thailand.

NINIA SEBAE SEBAE (Common Redback Coffee Snake). MÉXICO: CAMPECHE: Municipality of Ciudad del Carmen, 2 km E Escarcega. 11 October 1993. Mario Mancilla Moreno. Verifiifed by Fernando Mendoza Quijano. Museo de Zoologia, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC-06181). One adult male. First state record; extends known range 178 km NE of nearest record at Palenque, Chiapas [Smith 1943, Proc. U.S. Nat. Mus. 93(3169):393–504] and is about 40 km S of Chuina, Campeche, the southern locality for *Ninia s. morleyi*, the other subspecies recorded from the Yucatán Peninsula. The presence of both races in close proximity in this region shows a need for further study of variation in this species.

Submitted by **MARIO MANCILLA MORENO** and **ALEJANDRA RENDON ROJAS**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70–399, México, Distrito Federal 04510, México.

OPISTHOTROPHIS BOONSONGI (Boonsong's Stream Snake). THAILAND: LOEI PROVINCE: Amphoe Phu Rua. Two specimens captured at night in Nam San Noi Stream, 700 m elev. 26 April and 8 May 1993. Tanya Chan-ard. Both verified by Edmond V. Malnate. Thailand National Research Council, Bangkok (TNRC 52-3884 and TNRC 52-3885). Second and third specimens of this species on record; holotype was discovered approximately 40 km W of the site of capture of these two specimens (Taylor and Elbel 1958, Univ. Kansas Sci. Bull. Vol. 38, Pt. 2, No. 13, p. 1156).

Submitted by **MEREL J. COX**, 695/17 Pracharaj Road, Soi Pracharaj 19, Bangsue, Bangkok 10800, Thailand.

OVOPHIS TONKINENSIS (Tonkin Pitviper). PEOPLE'S REPUBLIC OF CHINA: HAINAN PROVINCE: Lingshui County, Diaoluo Mount (Diaoluo shan), stream in the Mengshui forest exploitation. 29 April 1983. Fu Boliang. Verified by Cen Jianqiang. Shanghai Museum of Natural History (SMNH 4096). First record for China; previously known only from northern Vietnam. Also, first record for Hainan Island of a member of the *Ovophis monticola* group (Zhao 1991, Herpetofauna and zoogeography of Hainan Island. *In* Zhao (ed.), pp. 354–363. From Water Onto Land. China Forestry Publ. House, Beijing; Zhao and Adler 1993, Herpetology of China. SSAR Contrib. Herpetol. 10:1–522). Although this snake is closely allied to the Chinese *Ovophis monticola makazayazaya* (sensu Zhao and Adler 1993), differences in scalation warrant a specific distinction (David, unpubl. data).

Submitted by **PATRICK DAVID**, Muséum National d'Histoire Naturelle, Laboratoire de Zoologie (Reptiles & Amphibians), 25 Rue Cuvier, F-75005 Paris, France.

THAMNOPHIS SAURITUS (Eastern Ribbon Snake). USA: ILLINOIS: Johnson Co: Thorne Pond, 2.1 km NE Belknap, SW Sec. 31, T13S, R3E. 2 June and 16 June 1988. R. A. Brandon, S. R. Ballard, and R. Weck. Photo vouchers, Southern Illinois University at Carbondale (SIUC R–2843, 2 animals, and SIUC R–2844); 5 August 1988. R. A. Brandon, S. R. Ballard, and J. Neth. Photo voucher (SIUC R–2845) and 4 offspring stillborn in captivity (SIUC R–2091–2094); near Heron Pond Nature Preserve. 14 November 1988. M. Hutchison. SIUC R–2158; 12 July 1986. D. Hutchison and R. Hutchison. INHS 10756. SE 1/4 NE 1/4 Sec. 31, T13S, R3E. 21 April 1995. E. O. Moll. Photo voucher (SIUC R–2846). First records for county. Massac Co: Mermet Lake. 20 July 1963. L. C. Richardson. SIUC R–364; 20 July 1963. J. Henderson. SIUC R–356. Round Lake, Mermet Lake Conservation Area. 17 July 1963. F. Robinson. UIMNH 56497–56498. Mermet Lake Conservation Area. 25 April 1991. A. Gerard. Photo Voucher (SIUC R–2849). First records for county; all but last specimen previously identified as *Thamnophis proximus*. Pope Co: 1.6 km W New Liberty. 17 June 1989. S. Karsen. SIUC R–2173. First record for county. Pulaski Co: 2 km S Perks. T. Fink. 25 April 1989. SIUC R–2167. Post Creek Cutoff at Route 169, E of Karnak. 5 August 1988. R. A. Brandon and S. R. Ballard. Photo voucher (SIUC R–2848); near juntion of Limekiln Slough and Cache River, NW Sec. 21, T14S, R1E. 9 May 1992. A. Gerard. 8-mm video voucher SIUC R–2847. First records for county. This state endangered species previously was known in Illinois only from seven specimens collected in or near the Wabash Border Division of Richland and Wabash counties before 1900 (Morris and Smith 1981, pp. 21–33 *In* Endangered and Threatened Species of Illinois. Illinois Dept. Conserv.; Rossman 1962, Copeia 1962:741–748; Rossman 1963, Florida St. Mus. Bull. 7:99–178; Rossman 1970, *Thamnophis sauritus*. Cat. Amer. Amph. Rept. 99.1–99.2), and an undocumented sight record from western Lawrence County (Thurow and Sliwinski, Chicago Herpetol. Soc. Bull. 26:129–132). These new records confirm the continuing presence of this species in Illinois some 150 km farther south in the Cache Biver and Ohio River drainages south of the Shawnee Hills.

Submitted by **RONALD A. BRANDON**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901-6501, USA, and **SCOTT R. BALLARD**, Illinois Department of Natural Resources, Division of Natural Heritage, 4521 Alton Commerce Parkway, Alton, Illinois 62002, USA.

TRIMORPHODON BISCUTATUS (Lyre Snake). MÉXICO: BAJA CALIFORNIA SUR: Isla San José, Gulf of California, NE portion of island in Arroyo Palmita Sola (25°03'15"N, 100°39'50"). 16 October 1994. Clark R. Mahrdt. Verified by Brad D. Hollingsworth. LACM PC 1267 adult male. Species has also been reported from the Gulf of California islands of Cerralvo, Danzante, San Marcos, and Tiburon (Murphy and Ottley 1984, Ann. Carnegie Mus. Nat. Hist. 53:207–230; Ramirez 1989, Herpetol. Rev. 20:76); represents the first record for Isla San José.

Submitted by **CLARK R. MAHRDT**, Southwest Biological Associates, 9847 Willow Lane, Escondido, California 92029, USA, and **L. LEE GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

VIRGINIA VALERIAE (Smooth Earth Snake). USA: TENNESSEE: Rutherford Co: cedar glade located along N border of Fall Creek Road (36°00'42"N, 86°26'18"W). 21 April 1995. B. T. Miller. Verified by J. L. Miller. Middle Tennessee State University (MTSU 104-S.) New county record; extends the known distribution into the Inner Central Basin of middle Tennessee and decreases the width of the hiatus separating *V. v. valeriae* and *V. v. elegans* (Powell et al. 1992, Cat. Amer. Amph. Rept. 552.1–552.6).

Submitted by **BRIAN T. MILLER**. Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

Confirmation of a Range Extension for the Pine Woods Snake (*Rhadinaea flavilata*)

The range of *Rhadinaea flavilata*, the pine woods snake, is restricted primarily to disjunct areas along the coasts of North Carolina to eastern Louisiana, including most of Florida (Conant and Collins 1991; Myers 1967). One anomaly in this distribution, from Aiken County, South Carolina, extended the range 150 km from the coastline and 145 km from the closest previous record (Young 1988, as shown in Conant and Collins 1991). This observation was based on a single specimen collected in 1987. Here we confirm that range extension with the addition of nine new individuals of *Rhadinaea flavilata* captured between 1987–1994.

Specimens of *Rhadinaea flavilata* were captured during routine surveys on the Department of Energy's Savannah River Site (SRS) by researchers from the Savannah River Ecology Laboratory (SREL). All snakes were captured by lifting woody debris and cover boards or checking pitfall traps (Gibbons and Semlitsch 1991); individuals were then returned to the laboratory for measurement (SVL, tail length, and in most cases, mass). All individuals were released because of the rarity of this species and the ongoing monitoring of SRS herpetofaunal diversity by SREL researchers.

TABLE 1. Captures of *Rhadinaea flavilata* on the Savannah River Site.

Site	Date	Method[1]	Sex[2]	SVL[3]	Tail[3]	Mass[4]
Dry Bay	9 May 87	L	M	23.4	9.5	5.60
Dry Bay	28 Sept 87	P	M	23.5	3.3	6.14
Bay 11	25 Oct 87	P	M	22.1	7.9	5.58
Bay 11	27 Oct 87	P	M	23.1	10.1	6.62
Dry Bay	27 Oct 87	L	M	23.4	9.5	—
Big Squirrel Bay	1 May 88	L	J	9.9	3.8	0.80
Dry Bay	15 June 88	P	F	22.4	9.3	4.96
Dry Bay	25 May 89	B	J	12.6	5.1	1.28
Dry Bay	26 May 94	B	M?	14.3	5.1	2.02
Dry Bay	11 Aug 94	B	M	16.6	6.1	2.71

[1] Capture method: P = pitfall; L = under log; B = under cover board
[2] M = male, F = female, J = juvenile
[3] centimeters
[4] grams

All nine *Rhadinaea flavilata* captured since Young (1988) were found on the SRS in Aiken County, South Carolina; pertinent data are presented in Table 1. Capture sites form two distinct areas: Bay 11 and Big Squirrel Bay are located within several hundred meters of each other, and both are separated from Dry Bay by 5 km. Two other *R. flavilata* have been captured on the SRS but were not measured. Both were collected at the Dry Bay locality.

These captures suggest that at least two populations of *Rhadinaea flavilata* exist on the SRS and confirm the initial range extension of this species by Young (1988). Based on the available data, we propose that the actual range of *R. flavilata* extends between the SRS and the coastline, at least along the Savannah River and probably in some discontinuous way throughout South Carolina and Georgia. Our logic is based on several aspects of the biology of this species. The primary habitat of *R. flavilata*, wet pine flatwoods (Conant and Collins 1991), is common between the SRS and the coastline in both South Carolina (Bennett and Poland 1989) and Georgia (Wharton 1978). In addition, the secretive nature of this species (Conant and Collins 1991; Martof et al. 1980) makes it unlikely that individuals would be easily found. Even with the intensive sampling on the SRS, that began in 1966 (Duever 1967) and has yielded more than 6000 snake captures (Gibbons et al., unpubl. ms.), no *R. flavilata* was captured during the first 22 years. We predict that drift fences with pitfall traps or cover board arrays, set in typical *R. flavilata* habitat, would reveal other non-coastal populations of this clandestine species in South Carolina and Georgia, as well as additional populations on the SRS.

Acknowledgments.—Research and manuscript preparation were supported by Contract DE-AC09-76SROO-819 between the U.S. Department of Energy and the University of Georgia's Savannah River Ecology Laboratory.

BOOK REVIEWS

Das Tierreich. The Animal Kingdom. Part 109. Family Gekkonidae (Reptilia, Sauria) I. Australia and Oceania. Aaron M. Bauer, Editor, this volume. With contributions from Klaus Henle. 1994. Verlag Walter de Gruyter, Berlin and New York, i–xiii + 306 pages. Hardcover. US $386.00 (DM 560). ISBN 3-11-014114-0.

Das Tierreich Part 109 covers 23 genera, 173 species, and 19 subspecies of geckos from Australia and Oceania. It is clear that this volume is much improved with respect to the 1965 version of Wermuth and includes all of the numerous recent findings and changes in nomenclature and distribution. Klaus Henle contributed to the basic accounts for some species. All islands to the north and west of Papua New Guinea and Irian Jaya, as well as the Pacific islands under Japanese and Philippine control, the Galapagos Islands, and the nearshore islands of the Americas are excluded. Australia's island territories, including those in the Indian Ocean are, however, covered. Whereas all island groups politically part of Papua New Guinea have been included, the only portions of Indonesia incorporated in this volume are mainland Irian Jaya and its immediately adjacent nearshore islands. The remainder of Indonesia will be included in volume five of the series. A general map is provided, locating all major island groups in the Pacific. Island nomenclature follows Motteler (1986), which is the commonly accepted reference. Fifty-three point locality maps, based on museum records and published sources, illustrate the distribution of each species and subspecies. Where identifiable, all type-localities—but only in this area—are indicated on the maps. Most of these maps combine the distributions of several species, such that some of them are very difficult to read (e.g., map 2 with seven species and five type-localities, map 19 with six species and nine type-localities). Overlap of mapped distributions is limited but such a choice was apparently not always possible. Also, map 4A is placed illogically before map 4. A general key is given for all the genera of Pacific geckos and directs readers to the page where the genus first appears. Each generic account includes a synonymy presenting all names applied to the genus in whole or part, and their type-species and variants. This is followed by a statement of distribution and a "Comments" section highlighting systematic and taxonomic information or problems. The complete references may be found in the "Literature Cited" section following the text. A complete list of species referred to each genus and a key to Pacific region species follow the list of generic references. Extralimital species are marked by an asterisk in the species referred list.

For each genus and species, Bauer arranged bibliographic references into 15 broad categories (not 13 as stated on page vi): Behavior, Biology, Conservation, Distribution, Ecology, Karyology, Morphology, Osteology, Paleontology, Parasitology, Phylogeny, Physiology, Reproduction, Taxonomy, and Zoogeography. They are not classified alphabetically but in a more logical way which, however, necessitates a longer time to search for one category. The category dealing with parasites is variously called "Parasitology" (pages 105, 123, 126, 142, 150, 171, 189, 205, 209, 214, 215, 216) or "Parasites" (pages 9, 112, 137, 141, 178, 183); and once with a typographic error ("Parasitzes," p. 222). It is unfortunate that a category such as "Molecular studies" (including electrophoresis, DNA sequencing, etc.) was not included.

Species accounts are arranged alphabetically as for the generic accounts except that chresonymies are provided instead of synonymies. The chresonymies in this book are not meant to be exhaustive, although they do contain all names proposed for each taxa as well as a broad selection of other citations, including all of those listed by Wermuth (1965) and Cogger et al. (1983). Revisionary or review works pertinent to each taxon are also included in the chresonymies as are regional herpetofaunas or faunal lists (including significant field guides or other popular and semi-popular works). Names appear verbatim with the full generic name provided unless it appeared in abbreviated form in the description of a new name. Page numbers in the chresonymy citations refer to the first or, in some cases, the primary use of the name in the work in question (always the first use in the case of new names). Effort has been made to correctly date publications cited, a practice that is valuable and generally uncommon. Replacement names, emendations, and incorrect subsequent spellings are noted as such in association with their earliest chronological use. Type localities appear verbatim and type specimens and their present status are identified whenever possible. As in the case of genera, species "References" sections provide citations to primarily biological works, usually not otherwise cited in the chresonymies. However, the choice of placing a bibliographic reference in the chresonymies list or in the "References" list sometimes seems arbitrary. Sometimes, as for *Gehyra membranacruralis*, Bauer (p. 86) gives useful unpublished information in a "Comments" section, thus orienting future research. A particular problem in the compilation of this work was encountered with respect to the work of Wells and Wellington (1984; 1985a, b). These authors have introduced many new names and resurrected others, frequently with minimal justification. According to the International Commission on Zoological Nomenclature (1991) decision, nomenclatural problems generated by the works in question were considered case by case by Bauer. With the exception of *Cyrtodactylus sadleiri*, he has not accepted any of the new species described by these authors. Among the many new generic names proposed by Wells and Wellington, Bauer accepted only *Christinus* as valid.

The bibliography is exhaustive, nearly complete, and includes 1465 references. Although the book went to the publisher by mid-1993, it is not clear when the bibliography was completed since some 1993 references were included while others were not. Two journals have the same title, *Herpetofauna*, one edited in Germany (Weinstadt) and the other in Australia. It is not clear in Bauer's bibliography whether *herpetofauna* (sic) deals with the German journal and *Herpetofauna* (sic) with the Australian one. However, the German journal uses the lower case format so I suspect Bauer followed this convention. The reference of Henderson et al. is without a date but should be 1976. Several typographic and presentation errors exist on most pages, but with the large number of references these were inevitable. Several author names are mispelled: Bourett (p. 117) for Bourret, Ebel (p. 119) for Elbel, Pasteuer (p. 160, 163) for Pasteur, Sauvge (p. 222) for Sauvage, ... The reference of Gill (1993 [= 1993a]) on page 125 is not followed by a or b and the one of Brygoo (2992) on page 225 corresponds to Brygoo (1991). The most unfortunate typographic error is on the spine of the book, Gekkoniade for Gekkonidae but Bauer himself certainly had no proofs for the cover or spine of the book. An index is provided with all the genera and species names used in the book, including chresonymies.

Regional accounts are placed after the bibliography and this part will be very useful to herpetologists. I will comment on some small mistakes. Clipperton Island was erroneously incorporated into French Polynesia (p. 284). *Nactus pelagicus* is wrongly re-

ported from the Society Archipelago in French Polynesia. This is also true for *Hemidactylus frenatus* which never was reported from the Marquesas but only from Tahiti (Society Archipelago) where it was first recorded in 1988 (Petren et al. 1993). Two recent papers dealing with Easter Island geckos were omitted (Klemmer 1989; Ineich and Ota 1993). In the addendum (p. 285), Bauer mentioned several relevant recent papers; Darevsky and Orlova's (1993) discussion of *Lepidodactylus lugubris* should be added. However, most 1993 papers were not available for inclusion at the time of submission.

I will now offer specific comments on some species, reviewed alphabetically, giving more attention to those which are widely distributed and therefore more difficult to analyze.

Gehyra mutilata: Pernetta (1983) reported the species from New Guinea, Matsui et al. (1985) from Sabah (Borneo, Malaysia), Brown and Alcala (1961) and Ross and Lazell (1991) from the Philippine Islands, four references not in the bibliography. Duméril and Bibron (1836:354–355), Boettger (1895), Schmidt and Necker (1933), Slevin (1934), Webb (1972), Clapp (1975), Jones (1979), Werner (1980), and Wiles et al. (1989), all authors which mention this species and figure in the bibliography are not listed in the species account. Useful information on the reproduction of this gecko in French Polynesia is also given by Ineich (1987). Two important references, one on the reproduction of this species (Rose 1982), the other on anatomy (Chou 1977), are missing. In the "References" section, Chou (1978) in "Ecology" is listed as Chow (1978). Lambert (1987), a reference not found in the bibliography, listed the species from the Seychelles under *Gehyra multilata* (sic). Two important references concerning the parasites of *Gehyra mutilata* were omitted (Ali and Riley 1983; Kennedy et al. 1982).

Gehyra oceanica: Useful information or distribution records for this species are given by several authors listed in the bibliography but not in the species account: Roux (1913), Schmidt and Necker (1933), Higgins (1943), Fisher (1948), Whitaker (1970), Clapp and Sibley (1971), Cochereau (1974), Clapp (1975, 1977), Heatwole (1975), Sabath (1981), Gibbons and Zug (1987), Crombie and Steadman (1989), and Wiles et al. (1989). The reference of Rivière (1979) was omitted from the bibliography. It is not clear why Schmidt (1921) was placed in the chresonymies and Schmidt (1922) in the species references under "Distribution." Additional information on the reproduction and eggs of this species in French Polynesia can be found in Ineich (1987). Ineich (1990a) is correctly placed in the "Distribution" section, but this is not the case with Ineich (1990b) which refers to another species, *Lepidodactylus lugubris*.

Gekko vittatus: Sternfeld (1920) reported the species from Belau, Roux (1913) from Santa Cruz (Solomon), and Pernetta (1983) from New Guinea; all three references are not cited in the species account, and the last one is absent from the bibliography.

Hemidactylus frenatus: Boettger (1895), Liner and Dundee (1969), Amerson and Shelton (1976), Mechler (1968), Jones (1979), Murthy (1987), Wiles et al. (1989), Rodda et al. (1991), and Gill (1993a) [reported by Bauer for *Gehyra oceanica* but not for *H. frenatus*] are not mentioned. Note however that for widespread species Bauer excluded many references regarding extralimital biological factors and only selected references from Asia and other areas were included. In the "Reproduction" section of references, "Guillett et al. (1982)" corresponds to Guillette and Jones (1982). The references of Parker (1925), Dammerman (1948), Brown and Alcala (1961), Ross and Lazell (1971), Blanc (1972), van Eijsden (1982), Cheke and Lawley (1983), Pernetta (1983), Lin and Cheng (1984), Cheng (1987, 1988) and Dring et al. (1990) are not cited in the bibliography but they all report on this species. Four major references about the parasites of this gecko are absent from the bibliography (Ali and Riley 1983; Tenorio 1985; Upton et al. 1991; Watermolen 1992).

Hemidactylus garnotii: Smith (1923), Steiner and McLamb (1982), Smith (1983), Dring et al. (1990), Stevenson and Crowe (1992), and Crowford and Somma (1993) deal with this species but are not mentioned in the bibliography. Some references listed in the bibliography are not reported under this species account: Werner (1900), Schmidt (1927), Fisher (1948), Taylor and Elbel (1958), Dryden and Taylor (1969), Ely and Clapp (1973), Amerson and Shelton (1976), Jones (1979), Biswas and Sanyal (1980), and Allison (1982). Tenorio's (1985) report of parasites in this species was omitted in the bibliography.

Hemiphyllodactylus typus: Roux (1913) reported a male *Lepidodactylus crepuscularis* (= *H. typus* according to Bauer) with 13 preanal pores, an important fact considering that *H. typus sensu stricto* is all female; this was not highlighted by Bauer. Meier (1979) reported *Lepidodactylus crepuscularis* from New Caledonia but it is impossible to know if this refers to *Hemiphyllodactylus typus*, *Lepidodactylus lugubris*, or another species owing to insufficient information. Several authors cited in the bibliography are not reported in this species account: Fisher (1948), Brown and Fehlmann (1958), Taylor and Elbel (1958), Jones (1979), and Biswas and Sanyal (1980). The "Distribution" section for this species is really unclear since Tonga appears two times and geographic order was not respected. Also, the Pitcairn Group, reported later (p. 284), was here omitted.

Heteronotia binoei: The reference of Moritz et al. (1991) about the parasites of this gecko is lacking.

Lepidodactylus lugubris: Several papers reported in the bibliography were omitted in the account of this species: Schnee (1904), Boulenger (1912), Schmidt and Necker (1933), Higgins (1943), Fisher (1948), Brown and Fehlmann (1958), Chrapliwy et al. (1961), Mechler (1968), Fitch (1970), Amerson (1971), Clapp and Sibley (1971), Stoddart (1971), Quay (1974), Clapp (1975, 1977), Heatwole (1975), Marshall (1975), Amerson and Shelton (1976), Henderson et al. (1976), Clapp et al. (1977), Jones (1979), Meier (1979), Biswas and Sanyal (1980), Pernetta and Black (1983), Wiles et al. (1989), Chazeau and Bauer (1991), and Rodda et al. (1991). An important reference on the parasites of this gecko was omitted (Upton et al. 1991). Some references dealing with this species are absent from the bibliography (Tanner 1948; Mertens 1958; Peters and Donoso-Barros 1970; Cuellar 1977; Rivière 1979; Miyata 1982; Pernetta 1983; Mudde and van Dijk 1984; Cheng 1987; Stokes and Cogger 1987; Ineich 1988, 1992; Klemmer 1989; Brown et al. 1991; Cameron and Cogger 1992; Saint Girons and Ineich 1992; Ineich and Ota 1993; Villa 1993; and Volobouev et al. 1993). Hoogmoed (1989), mentioned on page 158, is absent from the bibliography. On the same page, Bauer states that *Lepidodactylus intermedius* could be a valid subspecies of *L. lugubris*, following Auffenberg (1980:74). Such a view is unrealistic because *L. lugubris* is clearly referable to a unisexual clone according to its type material located in the Paris Museum, and thus consideration of any subspecies for this unisexual gecko is inappropriate. I have examined the types of *L. intermedius* and they clearly belong to a different valid bisexual taxon which could however be a junior synonym of *Lepidodactylus lombocensis* Mertens, 1929. Bauer's distribution map of this species covers only the Pacific region and thus several type-localities reported in the chresonymies are not figured on the map. "Guillette & al. 1982" in the "Reproduction" section of the references corresponds to Guillette and Jones (1982).

Pernetta and Watling (1979) are not included for *Lepidodactylus manni*. The same applies for Pernetta and Black (1983) about *Lepidodactylus magnus*, *L. novaeguineae*, and *L. orientalis*. For *Lepidodactylus pulcher*, Werner (1900), Vogt (1912), and Brown and Parker (1977) are not mentioned. For *L. pumilus*, Brown and Parker (1977) and Pernetta and Black (1983), and for *L. shebae*, Brown and Parker (1977) are not reported. Concerning *Lepidodactylus woodfordi*, several authors reporting the species are not cited: Boulenger (1898), Werner (1900), Vogt (1912), Sternfeld (1920), Taylor (1922), Brown and Parker (1977), and Brown and Alcala (1978). Ineich (1987:86–87) considered the French Polynesian bisexual populations as a species distinct from *L. lugubris* and referred them to *L. woodfordi*, subsequently considered a valid species (see also Hanley et al. 1994).

Bauer states that a new species of *Lepidodactylus* will be described from Vanuatu (p. 282), another from Belau (p. 283), together with the resurrection of *Gecko moestus* as a valid species of that genus (p. 158), and a new species of the genus *Gekko* from Belau (p. 112), all unpublished data. However, he does not mention the two new species reported from French Polynesia, one from Takapoto Atoll and the second from the Marquesas by Case et al. (1994), a paper that appeared after this volume went to press.

Nactus pelagicus: The references of Wiles et al. (1989) and Gill (1993a) are lacking.

Marshall's (1975) report of a *Perochirus* sp. from the Carolines is not included under this genus by Bauer. Sameit (1986, 1988) deals respectively with *Rhacodactylus auriculatus* and *R. trachyrhynchus* but these papers are not in the bibliography.

Despite the lack of some bibliographic references (impossible to avoid with such an important amount of information) Bauer's work is considerable and of excellent quality. It will help all herpetologists dealing with Pacific lizards and is a big step forward in our knowledge of this area. It will be a necessary tool and should facilitate rapid progress in Pacific herpetology. Such a book should have a nice place in the libraries of people interested in geckos. I can only hope that forthcoming volumes will be of the same quality but strongly recommend that subsequent authors carefully check the proofs to avoid typographic errors similar to those in this volume. I also regret that the high price of this book will certainly limit its diffusion.

Revised Catalogue of the Herpetological Collection in Turin University I. Amphibia, by Elena Gavetti and Franco Andreone. 1993. Published by Museo Regionale di Scienze Naturali, Via Giolitti 36, 10123 Torino, Italy. Catalogue series vol. 10, 185 pages (including 13 black-and-white plates), clothbound, 70,000 lira (about US $43). ISBN 88-86041-08-X.

The herpetological collection of the Università di Torino is relatively small (15,000 specimens) but is, nevertheless, of considerable historic importance. It was initiated with specimens collected by Vitaliano Donati in Egypt in 1759 and enlarged by two former directors of the museum (Franco Bonelli and Giuseppe Gené) with collections from the Piedmont region of northwestern Italy and from Sardinia, respectively. Later, the museum's own scientific personnel, among them some of the leading herpetologists of Italy (Camerano, De Betta, Lessona, and Peracca), further enriched the holdings from their own field work and with specimens obtained from compatriots travelling in distant parts of the world (Abruzzi in East Africa, Borelli in South America, De Filippi in Japan, Australia, and Persia, Fea in Burma, Festa in South America, North Africa, and the Middle East, and Zavattari in Albania, among many others). In addition, specimens from all parts of the world were added through purchase or by exchange with other museums. In particular, it was Mario Peracca (1861–1923), a wealthy member of the nobility who was also a trained zoologist, who added specimens from throughout the world and described numerous species. The collection of amphibians in Turin is thus broadly representative of the world's species and, moreover, contains types of 42 taxa.

This book is an annotated listing of Turin's entire collection of Amphibia and is an expansion of the simple list published by Elter, "La Collezione Erpetologica del Museo di Zoologia dell'Università di Torino" (1981 [1982]). Gavetti and Andreone's book is divided into several sections: a short history, a detailed catalogue of specimens from the two associated museums (zoology and comparative anatomy), a listing of types including designation of lectotypes, references, and an index, plus 52 photographs of the type specimens. The catalogue of specimens lists the registration number (MZUT and MACUT are the respective acronyms for the two museums), the locality, collector or donor, and the number of individuals catalogued under each number. Lectotypes and paralectotypes are designated for five species: *Molge italica* Peracca, 1898 (now *Triturus italicus*); *Hylodes discoidalis* Peracca, 1895 (now *Eleutherodactylus discoidalis*); *Paludicola Borellii* Peracca 1895 (now *Pleurodema borellii*); *Rana aluta* Peracca, 1893 (now *Mantidactylus alutus*); and *R. opiparis* Peracca, 1893 (now *M. opiparis*). Detailed descriptions are given for each lectotype. The amphibian types held by Turin include taxa described by Boulenger, Camerano, Fatio, Gené, Lataste, Lynch, Méhelÿ, Peracca, W. Peters, Savi, Thomas, and Werner. The photographic illustration of each of these types, sometimes including several views, is a special and valuable feature of this book.

The extensive annotations provide useful information for many species. For example, previously unreported type material of several species is announced, corrections to Elter's earlier list of Turin specimens are made, and questions are raised concerning the type designations of some specimens in other museums. In one instance (*Oreophryne biroi* of New Guinea), Turin possesses a heretofore unrecorded syntype from a type series that was otherwise destroyed in Budapest. In another annotation, for a specimen of *Proteus anguinus,* it is stated that "This individual lived in the Museum without being fed from October 1873 to 22 August 1877." There are relatively few typographical errors.

This is a well-produced, complete catalogue with many features that could well be imitated in future inventories of important herpetological collections. We eagerly await the announced volumes on Turin's reptiles.

Snakes, Lizards, Turtles, Frogs, Toads & Salamanders of New Mexico, by Michael A. Williamson, Paul W. Hyder, and John S. Applegarth. 1994. Sunstone Press, Santa Fe, New Mexico. iv + 176 pp., 126 color photos. Soft cover. US $19.95. ISBN 0-86534-233-4.

This publication, like many of the smaller regional field guides, is paperback and small enough (215 mm x 140 mm) to fit in a pocket. It contains a brief introduction to the use of the guide in the form of a foreward and very brief notes on specimen preservation, and captive care. A dichotomous key to the 123 species recognized by the authors as occurring in the state is provided. The species accounts, which are each a single page in length, include color photographs and range maps. These illustrations occupy about one half of the page. Brief notes (sometimes one half line) on description, reproduction, distribution, and natural history fill the remaining space. Family introductions are also skimpy. Some have as few as four ["Family Testudinidae (Emydidae)"] or five (families Elapidae and Chelydridae) lines of text. The book concludes with short glossary and a bibliography. There is no index.

As a collector of regional herpetofaunal guides, I usually welcome new additions to my library. This book came as a considerable surprise. New Mexico is a state with few professional herpetologists. We generally communicate frequently, and have some idea of projects underway. Thus, the preparation of a state guide (*Amphibians and Reptiles of New Mexico*, by W. G. Degenhardt, C. W. Painter, and A. H. Price, University of New Mexico Press, Albuquerque, *in press*) has been enthusiastically anticipated and assisted for several years. It is remarkable that no one I know connected with New Mexico herpetology was aware of the Sunstone Press book until it was in press.

I am irritated by the price of this book. As a rough comparison, I calculated the price per page of this work and the recently published *The Reptiles of Virginia* by Joseph C. Mitchell (x + 352 pp. Hardbound) at $.1108/page and $.1104/page, respectively. While these are not exactly comparable books (the excellent Mitchell work is hardback and does not include amphibians), it is interesting, and seems to justify my pique.

The lack of editing in this book is its most apparent flaw. Nearly every page contains an error in spelling, punctuation, grammar or spacing. Bold printing is used in the species accounts, presumably to highlight important information, but is used inconsistently from one account to the next. In the bibliography John Applegarth's name is spelled "Applegrath." Absorb is spelled "abosorb" on page 17; parotoid is spelled "paratoid" or "paratiod" in all of the toad accounts; "tubercle" is sometimes spelled "tubircle" (e.g., p. 156); margin is spelled "margine" throughout; "gray" and "grey" are both used; "sack" is often used for "sac" (e.g., p. 17); chevrons is sometimes spelled "shevrons" (p. 92); species epithets *exsanguis* and *gaigeae* are spelled *exanguis* and *gaigae* throughout. There are also inclusions such as the sentence on page 79 with a "6" stuck at the end after the period. There are also several duplications such as this from page 97: "Tongue weakly notched at the tip. Head covered by large regularly shaped scales or "shields." Belly scales similar to those on the rest of the body and tail. Tail autotomous. Tongue weakly notched at the tip." And this from the account of the Sacramento Mountain salamander: "The young are similar in color but with a more pronounced dorsal stripe. Lacks both lungs and external gills. The young are similar in color but with a more pronounced dorsal stripe. As (sic) with the adults they lack both lungs and external gills." It appears the sentence was rewritten, but the original never edited out. Some repetitions are contradictory, as this from page 163: "LARVAE: To 1.25 in. (3.2 cm)" and on the same page, "Tadpole <1" in length." Some sentences are poorly written and thus confusing: "The ground color may be tan, yellow or some shade that closely approximates the ground color" (pg. 82). In the tiger salamander account on page 167 the authors state: "Distribution: Occurs in every county in New Mexico. Upper Sonoran to Pinon Juniper above 8,000 ft." Does that mean only above 8,000 ft? In the Natural History Notes sections of each of the leopard frog accounts is the note "A member of the leopard frog "complex." " Nowhere do the authors explain what the leopard frog "complex" might be. Nor do they explain that the notes "Protected (I)" and "Protected (II)" are state designations which correspond roughly to endangered and threatened, and that special permits are required for any activities involving these species. Contrary to this book (p. 72) neither species of *Coleonyx* is protected in New Mexico. Some of the errors are almost humorous: "Members of the genus *Kinosternon*, represented in our area, are semi-aquatic turtles with a reduced plastron (lower shell) and which produce a fowl smelling scent..." Moving from olfactory defense to olfactory offense, on page 137 we are told that the bullfrog "has reeked havoc with many native amphibian populations." In an unusually illuminating misspelling, the authors state "The Plateau Spotted Whiptail is the result of a series of hybredizations between..." And from the introduction to the order Anura (p. 136): "Most lack claws (or nails) hair, scales , or feathers." Such errors are extremely numerous, certainly in the hundreds. Stuart (1994) found one to six per page.

Of greater concern are the errors in content. In couplet 41 of the key to reptiles, the choices are: "Legs present," and "legs absent." Selecting legs absent leads to couplet 80; a choice between the collared lizard and the leopard lizard. Couplet 81 actually begins the snakes. On page 162, in the introduction to family *Pelobatidae*, The authors state: "Members of the genus *Bufo*, by contrast, have vertical pupils..." In the species account for the Jemez Mountain salamander (*Plethodon neomexicanus)* (p. 170) the distribution section says "Taos, Sandoval, Rio Arriba and Los Alamos counties." Despite considerable effort, this species has never been collected in Taos County (Marilyn Altenbach, pers. comm.). It would be a serious disservice to this endemic if consumptive interests, such as timbering, cited this reference to minimize the apparent vulnerability of the species to habitat degradation. Interestingly, the range map is correct in showing the distribution of the animal. In the account of the Texas toad (p. 160) distribution is given as: "South-central New Mexico (Dona Ana County) and lower Pecos R. drainage to the Texas Border." The range map, however, has no indicated range in Dona Ana County. On page 163 the authors state that Couch's spadefoot "tadpoles are especially prone to cannibalism." While tadpoles do not hesitate to feed on dead tadpoles, *couchii* does not develop a cannibalistic morph as far as I can tell.

The authors do not recognize subspecies in any of the species accounts. Thus, the account for *Sceloporus graciosus* lumps in the Mescalero Dunes taxon *Sceloporus arenicolus*. This is particularly puzzling in view of the fact that John Applegarth is a co-author of the paper which recognized *arenicolus* as a full species (Smith et al. 1992).

The Sonoran mud turtle account on p. 128 states: "marginal scales are all similar in size. In the accompanying photo, the raised tenth marginal characteristic of this species (Ernst and Barbour 1989) is visible. In the description section of the account on the Big Bend slider, *Trachemys gaigeae*, it is stated that "Males have long nails on the forefeet." Unlike *T. scripta* in the U.S., *T. gaigeae* does not have elongated front claws (Ernst 1992).

Despite the expectations created by the rest of the book, the range maps appear to be relatively free of significant errors. That brings up what I find the most troubling aspect of this book. There is no mention, much less acknowledgment, of any sources except John S. Applegarth, who "provided most of the data on which were based the maps and distributions." I find it incredible that a single herpetologist (even three!) could, based on his or her own field experience, have sufficiently complete knowledge of "123 species" over 122,000 square miles of habitat to construct complex range maps. Certainly there are compelling practical reasons (McCoy 1992) to acknowledge preserved collections and/or other information sources. Beyond that, it is somewhere between rude and unethical to omit such acknowledgment. Some collections might well deny future access in response (John Simmons, pers. comm.). Inevitably, serious doubt exists about the accuracy of these maps, because we lack any means of verifying the data used in their preparation. Stuart (1994) has noted a "puzzling (even disturbing)... striking similarity between many of the book's more detailed maps... and the New Mexico range maps drafted by Degenhardt et al..." That such concerns regarding the provenance of the maps must be raised is very troubling indeed.

New Mexico is an important region herpetologically. It is a unique transition area with elements of the faunas of the Great Plains, the Chihuahuan and Sonoran Deserts, the northern Sierra Madre Oriental, the Great Basin, and the southern Rocky Mountains. A book thoroughly covering the herpetofauna of New Mexico has long been needed. Sadly, this work falls far short of fulfilling that need at any level of herpetological interest.

Acknowledgments.—I thank Marilyn Altenbach for consulting her database on *Plethodon neomexicanus*. Conversations with Roger Conant, Hobart Smith, and John Simmons provided various views on several ethical points, which helped clarify my understanding. Jennifer Yocom, of the Rio Grande Zoo herpetology staff, helped highlight many of the errors. David Chiszar read and made comments on a draft of the manuscript. I am most grateful to them.

PUBLICATIONS RECEIVED

Verbreitung, kologie und Schutz der Schlangen Deutschlands und angrenzender Gebiete edited by Gruschwitz, M., Kornacker, P.M., Podloucky, R., Vlkl, W., and Waitzmann, M. 1993. Mertensiella 3. Softcover. 432 pp., US $25.00, ISBN 39801929-2-X.

A collection of 28 papers dealing with the distribution, ecology and conservation of the snakes of Germany and adjacent areas. All six of the extant German snakes *Coronella austriaca, Elaphe longissima, Natrix natrix, Natrix tessellata, Vipera aspis*, and *Vipera berus*) are treated as are the fossil snakes of Germany. All papers are in German, although English summaries and figure captions are provided for all papers. The volume contains over one hundred figures, photos and maps, including color plates of the snakes and their habitats. Most of the papers are in-depth studies dealing with the biology and conservation of the snakes in particular areas of Germany and the maps provided are especially detailed. This is the third volume of the series Mertensiella, published by the Deutsche Gesellschaft fr Herpetologie und Terrarienkunde. Earlier volumes treated the biology and conservation of *Lacerta agilis* (Volume 1, in German and English) and the evolution and biology of varanid lizards (Volume 2, English).

Bevarelsen af Danmarks Padder og Krybdyr edited by H. Bringsøe and H. Graff. 1995. Nordisk Herpetologisk Forening, Køge, Denmark. Softcover. 133 pp., DKr. 150,000 (approximately US $28.00) ISBN 87-985324-0-5.

This volume was issued in commemoration of the 50th anniversary of the Scandanavian Herpetological Society (Nordisk Herpetologisk Forening) and presents an up-to-date review of the conservation of Danish amphibians (14 species) and reptiles (six species). Each amphibian is treated in its own chapter, whereas the reptiles are considered together in a single contribution. Data on reproduction, general ecology, and conservation status are presented for each species, although different chapters have somewhat different emphases. The text is in Danish, with English summaries. The book is illustrated throughout, primarily in color. All species are figured, as are larvae of many of the amphibians and representative views of all major habitat types in Denmark. A short history of the Scandanavian Herpetological Society is also included.

A Standardized Protocol for Surveying Aquatic Amphibians, by Gary M. Fellers and Kathleen L. Freel. 1995. Technical Report No. NPS/WRUC/NRTR 95-01. U.S. Department of the Interior National Biological Service Cooperative Park Studies Unit. 117 pp. Available free from NBS Cooperative Park Studies Unit, University of California, Division of Environmental Studies, Davis, California 95616-8576, USA.

This is a detailed how-to manual for conducting aquatic amphibian surveys, and has been field tested at >2300 sites in California. Although the emphasis is on western U.S. amphibians, researchers in other areas will likely find this present work a useful companion to the more comprehensive volume by Heyer et al. (1994. Measuring and Monitoring Biological Diversity: Standard Methods for Amphibians. Smithsonian Inst. Press. 364 pp.).

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Techniques, Natural History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles or Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Natural History Notes or Geographic Distribution manuscripts; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, New Jersey Field Office, The Nature Conservancy, 200 Pottersville Road, Chester, New Jersey 07930, USA (tel. 908-879-7262).

Herpetological Review is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Karen Toepfer, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 600		$300
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 600	$150

For back orders only: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA (fax 314-977-3658).

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1995 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $25; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $30 for one year. All members receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $17. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $15; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Karen L. Toepfer, SSAR Treasurer, P.O. Box 626, Hays, Kansas 67601–0626, USA. Telephone: (913) 623-4258; Fax: (913) 625-8890; e-mail: aren@ksuvm.ksu.edu or aren@ksuvm.bitnet.

HERPETOLOGICAL REVIEW (ISSN: 0018-084X) is published quarterly in March, June, September and December by the Society for the Study of Amphibians and Reptiles at 303 West 39th St., Hays, KS 67601-1518. Application to mail at 2nd Class Postage rates is pending at Hays, Kansas with additional entry offices. **POSTMASTER:** Send address changes to *HERPETOLOGICAL REVIEW*, P.O. Box 626, Hays, KS 67601-0626.

Future Annual Meetings

1996 — University of Kansas, Lawrence, Kansas, USA, 24–29 July (Linda Trueb, Chair).
1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July (Theodore Pietsch, Chair).
1998 — University of Guelph, Guelph, Ontario, Canada, 16—22 July (James P. Bogart, Chair).

SSAR BUSINESS

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 1996 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson

2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include in situ behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.

3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on an herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president.

5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR with the exception of those applying for support of regional herpetological society projects. Membership dues must be paid (to SSAR Treasurer) no later than 31 December 1995 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project. (B) METHODS of carrying out the project. (C) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). (D) BRIEF RESUMÉ of the applicant or project coordinator. (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages excluding resumé and budget.

Applicants must designate to which of the five categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than 31 DECEMBER 1995 to be considered. Please include office and home phone numbers, as well as fax number and e-mail address if available. It is often necessary to

About our Cover

Box turtles (genus *Terrapene*) have figured prominently in recent discussions concerning international trade in pet turtles. [See Legislation & Conservation, p. 117 of this issue, for additional information.] According to a recent report prepared by Allen Salzberg for The Humane Society of the United States (Live freshwater turtle and tortoise trade in the United States, Nov. 1994, 39 pp.), "[D]uring the summer of 1994, every week, thousands of North American box turtles...were shipped out ... to supply the European pet trade." In what appears to be a classic conflict between conservationists and economic interests (chiefly Louisiana animal dealers), the U.S. Fish and Wildlife Service, despite opposition from SSAR, agreed to allow the export of 9750 *Terrapene carolina* during 1995. Scientists argued that populations of long-lived species such as box turtles cannot sustain this level of harvesting. The export allowance will be reexamined next year, and the quotas can go up or down.

The genus *Terrapene* consists of four species (*T. carolina, coahuila, nelsoni, ornata*) and is confined to the U.S. and México. Recent reviews include those by Iverson (1992. A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana. 363 pp.), and Ernst and McBreen (1991. Cat. Amer. Amphib. Rept. 511:1–6; 1991. ibid. 512:1–13).

The cover depicts an Eastern Box Turtle (*Terrapene c. carolina*) from Adams Co., Ohio, USA. The photograph was taken by **David M. Dennis**, a noted illustrator and photographer. This turtle served as the model for the commemorative poster prepared by Dennis for the First World Congress of Herpetology in Canterbury. David holds the position of Scientific Illustrator for the College of Biological Sciences at The Ohio State University in Columbus. He has become an internationally renowned illustrator of biological subjects, in particular of amphibians and reptiles, of which he is regarded as preeminent among the world's artists. He is perhaps best known to vertebrate biologists for the exquisite watercolors published in Duellman's *Hylid Frogs of Middle America* (University of Kansas Press, 1970) and in Smith and Brodie's *Field Identification: Reptiles of North America* (Golden Press, 1982). In addition to his talents as an illustrator and photographer, David is one of the two co-founders of SSAR, begun in Ohio in 1958 as The Ohio Herpetological Society. David's art work has appeared in numerous SSAR publications, and his now-famous multimedia presentations (in collaboration with Eric Juterbock and Kraig Adler) are staples at the SSAR annual meetings.

He took this photo using a Nikon FE-2 camera with a 105mm macro lens with Kodachrome 64 film with flash in a soft box. Separation and imaging by **Jim Bridges**, Herpeto Inc., Hollywood, Florida, USA.

contact applicants quickly. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1996. Successful applicants will be expected to submit a written report of the results of this support within a reasonable amount of time after the project year is completed. They are also encouraged to submit the results of research projects for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Julian C. Lee, Chair, SSAR Grants-in-Herpetology, Department of Biology, P.O. Box 249118, University of Miami, Coral Gables, Florida 33124, USA. Tel. (305) 284-6420, FAX (305) 284-3039.*

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

Annual Report (1995) Grants-in-Herpetology Committee

Five awards of $500 each in four categories were made this year, as follows:

Conservation.—**Christine Bridges**, University of Missouri-Columbia. Project title: "Effects of an agricultural chemical on tadpole swimming and feeding in the presence and absence of predators."

Laboratory Research.—**Allison Abell**, University of Chicago. Project title: "The relationship among male secondary sexual character expression, territorial aggression, courtship behavior, and mating success in *Sceloporus virgatus*."

Laboratory Research.—**Leslie Rye**, University of Guelph. Project title: "Analysis of two areas of intergradation between subspecies of common garter snake, *Thamnophis sirtalis*."

Field Research.—**Marguerite A. Butler**, Washington University. Project title: "The relative roles of intersexual and interspecific differentiation in the radiation of Greater Antillean *Anolis* lizards."

Travel.—**Michael S. Finkler**, Miami University. Project title: "Impact of egg content on post-hatchling size, body composition, and performance in the common snapping turtle (*Chelydra serpentina*)."

1995 Grants-in-Herpetology Committee.—Kelly Zamudio, University of Washington; Barbara Savitzky, Christopher Newport University; Anders G. J. Rhodin, Chelonian Research Foundation; Julian C. Lee, University of Miami; Randy Jennings, Western New Mexico University, Carole L. Hom, University of California, Davis; Lewellyn Densmore, Texas Tech University; A. Dale Belcher, Rio Grande Zoological Park (chair).

NEWSNOTES

Association of Reptilian and Amphibian Veterinarians

The Association of Reptilian and Amphibians Veterinarians (ARAV) is a non-profit international network of veterinarians and herpetologists whose goal is to improve reptilian and amphibian husbandry and medicine through education and idea exchange. The *Bulletin of the Association of Reptilian and Amphibian Veterinarians*, edited by Thomas Boyer, is published quarterly, and features peer-reviewed original articles on topics such as clinical cases, current therapy, species propagation, and literature reviews, as well as brief reports detailing clinical experiences and the exchange of ideas for direct practical application. Other articles concern captive husbandry strategies for the herpetoculturist.

In addition to their quarterly journal, ARAV also publishes papers delivered at their annual conference. The *Proceedings of the 1994 ARAV Conference* (available for US$30) contain the following titles (and authors): Physical examination of reptiles and amphibians (Paul Raiti); Common infectious diseases of reptiles and amphibians: an etiologic review, diagnostics and treatment recommendations (Mark Lloyd); Common parasitic diseases of reptiles and amphibians (Michael S. Bodri); Basic principles of therapeutics used in reptile medicine (Roger J. Klingenberg); Diagnostic techniques in reptile medicine; Common non-infectious diseases of reptiles (Wm. Kirk Suedmeyer); Current techniques in reptile anesthesia and surgery (R. Avery Bennett); Use of computed tomography as a diagnostic aid in the diagnosis of an abdominal mass in a box turtle (Karen Rosenthal and Amy Kapatkin); Chemotherapeutic treatment of a sarcoma in a corn snake (Karen Rosenthal); Two cases of anemia in reptiles treated with blood transfusions: (1) hemolytic anemia in a diamond python caused by an erythrocytic virus; (2) nutritional anemia in a bearded dragon (Helen McCracken et al.); Successful treatment of a urolith associated with a fungal cystitis in *Iguana iguana* (Nancy L. Anderson); Liver enzymes and pathology in runt crocodiles (*C. porosus*) (J. McInerney); MR of bowel using mineral oil as a contrast agent: a viable option in reptiles with long transit times (Paul Raiti and Nogah Haramati); Endoscopic examination of the urogenital tract in reptiles (Bernd Schildger); A review of allometric scaling with considerations for its application to reptile therapeutics (Janet C. Martin and Charles J. Sedgwick); Clinical approach to the chameleon patient (Scott Stahl); The Wyoming toad (*Bufo hemiophrys baxteri*): a review of causes of mortality in the captive population (Sharon K. Taylor et al.); Normal and pathological ultrasonographic anatomy of amphibians (Mark D. Stetter and Robert A. Cook); Pharmacokinetics of intramuscular administration of three antibiotics in bullfrogs (*Rana catesbeiana*) (James Letcher and Mark Papich); Problems with metabolic scaling of antimicrobial dosages in reptiles (Juergen Schumacher and Elliot Jacobson); The reptilian renal portal system and its effect on drug kinetics (Peter Holz et al.); Pharmacokinetics of enrofloxacin in juvenile Burmese pythons (*Python molurus bivittatus*) (Lee A. Young et al.); Use of long-acting ivermectin suspension in snakes (Meg Sutherland-Smith et al.); Trichomonas associated with ocular and subcutaneous lesions in geckos (Harry A. Miller et al.); Periodontal disease in lizards—a review of numerous cases (Helen McCracken and Christine A. Birch); Detection of antibodies against paramyxovirus (OPMV) on Mexican captive snakes

(Dulce Brousset et al.); Gallamine reversal in Cuban crocodiles (*Crocodylus rhombifer*) using neostigmine alone versus neostigmine with hyaluronidase (Mark L. Lloyd et al.); Snake hematology—practical considerations (Edward C. Ramsay and Thomas K. Dotson).

The ARAV invites all herpetologists and herpetoculturists to become members. Dues are US$30/year for members residing in the continental U.S., $35 for members in Alaska, Hawaii, Canada, México, Puerto Rico, and the Virgin Islands, and $40 for other countries. To join, or to obtain back issues of the *Bulletin*, please write to: *Wilbur B. Amand, Executive Director, ARAV, Box 605, 1 Smith Bridge Road, Chester Heights, Pennsylvania 19017, USA. Tel. (610) 358-9530, Fax (610) 892-4813.*

Litteratura Serpentium

Litteratura Serpentium is the bimonthly publication of the European Snake Society (E.S.S.). Since 1983, a Dutch and an English version have been published simultaneously. Articles are published on both snakes in nature and in the terrarium. The Editors are Rene van der Vlugt (email: R.A.A.van.der.Vlugt@ipo.agro.nl) and Cecile van der Vlugt-Bergmans (email: Bergmans@rel.wau.nl). The Treasurer is Guido Gomes, Pauwenveld 18, 2727 DE Zoetermeer, The Netherlands [Tel. +31 (79) 416592]. Membership fee for 1995 (volume 15): $40.00 (credit card payment). Back issues as well as cumulative indexes are available from the treasurer.

Information for U.K. residents: Chris Mattison, 138 Dalewood Road, Beauchief, Sheffield, S8 OEF, United Kingdom. Meetings: Next Snake Day will be held 28 October 1995 at the Conference Centre URETCO, Meidoornkade 24, Houten (Utrecht), The Netherlands. At the 1994 meeting more than 2000 attendees from Europe and the U.S. were counted.

Proposal for an African Herpetofaunal Biodiversity Program

This initiative is put forward to all relevant institutions and individuals in the hope that as many as possible will join together in working towards the aims of the program as outlined below. This communication invites you (and your organization) to consider being a part of this program, or, at least, to comment and put forward suggestions or amendments which you feel are desirable.

Introduction.—On a global scale, Africa and its islands fall within two biogeographical realms. These are the Palaearctic Realm and the Africotropical Realm. In the former, only three biogeographic provinces are represented. These are the Mediterranean Sclerophyll, the Sahara, and the Atlas Steppe. All of these occupy North Africa. South of these provinces is the Africotropical Realm with 29 biogeographical provinces being recognized. Two of the world's four "megadiversity" countries fall within this latter realm. They are Zaire and Madagascar (the other two are Indonesia and Brazil). While the mammal, bird, and even fish faunas are receiving much attention from conservationists, the herpetofauna remains much neglected with only the crocodiles and, to a degree, the chelonians receiving any major attention.

Aims.—The maintenance of present levels of biodiversity within this region depends on how well a number of essential requirements can be met. These requirements involve the following:

1) A consolidated inventory of the taxa present in the region, their distribution, and survival requirements.
2) An assessment and inventory of current conservation areas.
3) An assessment and inventory of critical conservation sites (whether or not presently conserved) based on existing distribution as well as the location of potentially important refuge areas in times of climatic extremes.
4) The monitoring of local and regional environmental change with particular attention to the areas identified under 2 & 3 above.
5) The implementation of a prioritized action plan to ensure that threatened species and systems are afforded appropriate attention.
6) The inclusion and involvement of local communities in the management and maintenance of conservation areas.
7) The assessment of the potential for the sustainable utilization and captive breeding of economically valuable species which could contribute to the economic development of local people while at the same time promoting the conservation of wild populations and their habitats.

In order for the program to be successful, a coordination center will need to be established. This would act as a clearing house for information and as a facilitator for international collaboration between official and non-governmental conservation bodies, research organizations, individuals, and other affected parties. This center would also assist in establishing overall priorities and in obtaining the international financial support required to implement these priorities. The coordinating center will also need to support an education program aimed at all levels of society from local people whose subsistence may depend on the areas needing conserving, through business and other agencies wishing to utilize these areas for development, and government and other political leaders who may be pressured by other interests. It will also need to develop, or otherwise acquire, an integrated, multi-level, and multi-purpose information system which can be used at local, national, and international levels to support planning and management decisions as well as assisting with primary research. In addition to the overall coordination center, the possibility of regional centers is also envisaged. These would coordinate local projects while maintaining close links with the overall center.

The program envisaged would preferably collaborate with, or involve, international bodies such as the IUCN, WWF, United Nations FAO, EarthWatch, the Biodiversity Foundation for Africa, and a wide range of universities, museums, government and non-government conservation bodies, as well as herpetological societies, reptile parks, and other interested persons and organizations.

The information provided above is of necessity somewhat limited but should give some idea of the proposed program. Comments from interested individuals and organizations will be appreciated. Details of completed, in progress, planned, and desired projects involving work on the African herpetofauna would be of great value. Once replies have been collated, a further document detailing the responses received will be sent out.

Comments and confirmation of interest in the proposed program should be sent to: *Lynn Raw, P.O. Box 200, Merrivale, 3291 South Africa. Tel: +27-331-431422 (home); +27-331-460796 (work); Fax: +27-331-460895; e-mail: Raw@zoology.unp.ac.za.*

SSAR World Wide Web Page

SSAR has begun a World Wide Web Page. Set your browser to

http://falcon.cc.ukans.edu/~gpisani/SSAR.html

and check us out. The site still is under construction, but more useful things are being added weekly. In addition to SSAR information, the web page also offers links to other herpetological on-line resources. FORMER OFFICERS, EDITORS, COMMITTEE MEMBERS: please review the file "SSAR Officers and Editors" to check that your data are up-to-date. This file will be used eventually in a history of the Society. The SSAR Web Page is administered by George Pisani (gpisani@falcon.cc.ukans.edu).

OBITUARY

Jeffrey Howard Black (1943–1995)

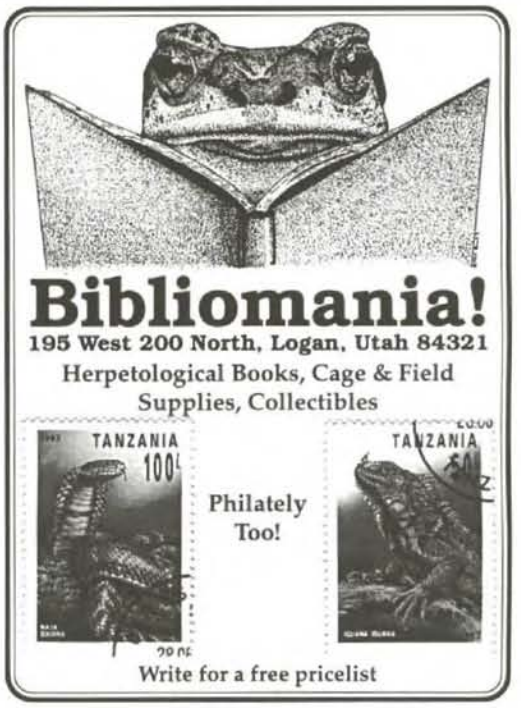
Jeffrey Howard Black, Ph.D., died suddenly of a heart attack on January 7, 1995 at his home in Roff in east central Oklahoma. Occurring at the apex of his life, this tragic, untimely death, saddens those who knew him.

Jeff grew up in Oregon where he was born on February 11, 1943 in Prairie City. After receiving a B.S. degree in 1965 from Oregon State University, he went on to earn an M.S. degree from the University of Montana in 1970. His M.S. thesis on *Bufo* in Montana predicted a life-long interest in amphibians.

I first met Jeff Black in the fall of 1967 when he entered the graduate program in zoology at the University of Oklahoma. For several years prior to this, Jeff had an active correspondence about his keen interest in toads (*Bufo*) with Dr. Arthur N. Bragg of our department. As a result of this interchange, he came to the University of Oklahoma to work on his doctorate with Dr. Bragg on *Scaphiopus*. Jeff was well into both his academic and research programs when Dr. Bragg retired and died soon after in 1968. Jeff was in limbo for a while. Then I took over as his major professor; it was my good fortune to work with and establish a friendship with this fine young student.

Jeff was awarded a Ph.D. in Zoology in 1973. His doctoral research, a study on the "Ethoecology of *Scaphiopus* (Pelobatidae) larvae in temporary pools in central and southwestern Oklahoma," kept him on the move after heavy rains to observe and record these fascinating amphibians that had for so many years consumed the energies of Dr. Bragg. While in graduate school, he received the Arthur N. Bragg Award in Natural History and the Ortenburger Award of the Phi Sigma Society.

Jeff started his academic professional career at Oklahoma Baptist University in Shawnee in 1973. Although he had a heavy teaching load, he found time to serve on the Shawnee School Board, and as Research Curator (1979–1982) at the Oklahoma City Zoo. Additionally, he worked with the Tulsa Zoo to develop a course in Zoo Biology, was a Research Associate in Herpetology with the Oklahoma Museum of Natural History, and held an Adjunct Professorship at Oklahoma State University. He was the main impetus in the formation of the Oklahoma Herpetological Society, for which he served as President in 1986, and and as editor of its bulletin, *Mountain Boomer*, for eight years. He served as Regional Societies Coordinator for the SSAR.



Jeff had broad interests in wildlife and conservation. I recall being notified of a find in one of Oklahoma's many caves to which I sent Jeff, as I could not respond at the time. He went, located and identified the salamander. This whetted his appetite for caves, and he became an avid spelunker, joining the State Grotto and publishing on the cave fauna of Oklahoma. In 1985 he received the President's Stewardship Award from the Nature Conservancy and in 1989 was selected the Oklahoma Educator-Conservationist of the Year by the Oklahoma Department of Wildlife Conservation. He served on the Herptile Committee of the Non-Game Program of the Oklahoma Department of Wildlife Conservation.

In 1988 Jeff moved to East Central Oklahoma University in Ada and was Professor of Biology at his death. That university honored him with their award for Teaching Excellence in 1992. He continued his public service while in Ada and at the time of his death was chair of the Collegiate Academy, and Director of the Oklahoma Junior Academy of Science, of the Oklahoma Academy of Science, for which he had also served as president in 1985.

Although Jeff Black planned to publish a book on the "The Amphibia of Oklahoma" which had been started by Dr. Bragg, teaching and other commitments compromised this effort. However, along with co-author Greg Sievert, he did complete a very popular, small field guide, "A Field Guide to Amphibians of Oklahoma," published by the Oklahoma Department of Wildlife Conservation in 1989. In addition to publishing widely on the herpetofauna of Oklahoma, he wrote a column, The Natural Way, for two small Oklahoma newspapers.

When he moved to Ada, Jeff purchased some acreage in nearby Roff, where he and his wife, Judy, raised exotic sheep. Judy is well known for her weaving, and they both traveled to England and Scotland to observe sheep and weaving. In addition to Judy, he leaves behind two sons and three grandchildren. I was very proud to have Jeff as my student, pleased to work with him and follow his success. He made significant contributions in many ways. He will be missed by his many friends, students, and colleagues. His death is also a loss to the state of Oklahoma.

LEGISLATION & CONSERVATION

Call for information on the status of amphibians and reptiles. This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information especially on the state and province level. Please send pertinent information to the Section Editor.

USA: Office of Scientific Authority: The OSA issued a Memorandum dated 24 March 1995 to the Office of Management Authority (OMA) concerning the export of box turtles harvested in Louisiana in 1995. The conclusion made by the OSA, after consultation with the Louisiana Reptile and Amphibian Task Force, is that there is no evidence to indicate that native box turtles are endangered or threatened in Louisiana. The export limit of Gulf Coast box turtles (*Terrapene carolina major*) and three-toed box turtles (*T. c. triunguis*) from Louisiana in 1995 has been set at 9750 individuals. According to existing export information, this represents 50% of the number of Louisiana-harvested *Terrapene carolina* believed to have been exported from the United States in 1993. Other justifications for allowing this harvest include statements that 1) box turtles mature earlier (4–10 years of age) and may be more resilient than Blanding's turtle (*Emydoidea blandingi*), a species for which additional mortality on adults has been shown to cause population declines (see Congdon et al. 1993. Conserv. Biol. 7:826–833) and 2) the Louisiana Department of Wildlife and Fisheries is committed to assuring that commercial harvest of box turtles is managed at a sustainable level.

All box turtles in the genus *Terrapene*, except *T. coahuila* (already an Appendix I species), were added to Appendix II of CITES in November 1994 (Buhlmann 1995. Herpetol. Rev. 26:67). Persons concerned about this export decision should communicate with the Office of Scientific Authority, U.S. Fish and Wildlife Service, Washington, D.C., and the Louisiana Department of Wildlife and Fisheries.

Critical New Zealand Habitat Preserved

Settlement has finally been reached in the long-running negotiations over the ownership and management of Takapourewa (Stephens Island) in the outer Marlborough Sounds, New Zealand. The future management of this sanctuary, one of international herpetological significance, has been of great concern to herpetologists, including the Society for Research on Amphibians and Reptiles in New Zealand (SRARNZ), which petitioned the New Zealand government for the conservation of this site.

Under an agreement reached in late 1994 between the New Zealand government and representatives of indigenous peoples, Stephens Island will become a closed Nature Reserve. This status will provide the maximum protection for the natural values which include the largest species of tuatara (*Sphenodon punctatus*), the only location for Hamilton's frog (*Leiopelma hamiltoni*), and habitat for seven species of lizards. *[Information taken from* SRARNZ Notes, *Number 13, 11 January 1995.]*

MEETINGS

Meetings Calendar

22–28 October 1995—3rd Latin American Congress of Ecology, Universidad de Los Andes, Mérida, Venezuela Fees are US $100 (regular) and US $70 (students). Contact Dr. Jaime E. Péfaur, Executive Secretary, III CLAE, Fax (58) 74 401286; e-mail CLAE@ula.ve.

26–29 October 1995—2nd Annual Conference of the Association of Reptilian and Amphibian Veterinarians (ARAV), Sacramento, California, USA. Contact Wilbur Amand, VMD, P.O. Box 605, 1 Smithbridge Road, Chester Heights, Pennsylvania 19017, USA. Fax (215) 387-2165.

28 October 1995—European Snake Society's Snake Day, Conference Centre URETCO, Meidoornkade 24, Houten (Utrecht), The Netherlands. Contact Chris Mattison, 138 Dalewood Road, Beauchief, Sheffield, S8 OEF, United Kingdom; or Anton van Woerkom, Utrecht University, e-mail: Anton.vanwoerkom@let.ruu.nl.

Herpetological Review Now On-line

A pre-publication listing of the contents of each issue of *HR* is now available from several on-line sources. Postings should occur approximately one month before the publication of the next issue. This service should be helpful to herpetologists in countries where mail delivery is unpredictable, as well as providing pre-publication information to other interested persons. *HR*'s on-line contents listing is available from the following:

Herp-Net — direct dial to 215-464-3562 (300–2400bps 8-N-1) or 215-698-1905 (9600, 14.4kbs) 24 hours per day. Select "Herp. Review" menu item.

Via **Usenet** newsgroup, "sci.bio.herp" (use any newsreader available on your network account), look for the posting "Herpetological Review Contents."

The **Herpetology World Wide Web at Harvard**, maintained by Michael Eisen, can be accessed at:
http://xta1200.harvard.edu:8000/herp
Then select the menu item "Current Contents of Herp Journals."

The **SSAR World Wide Web Page**, maintained by George Pisani, can be accessed at:
http://falcon.cc.ukans.edu/~gpisani/SSAR.html

Both the Harvard and SSAR web pages offer links to other web sites.

Via the **HERP-L** distribution list available to any Internet address. To subscribe send email to listproc@xtal200.harvard.edu with the phrase "subscribe HERP-L <your name>" in the body of the message.

On the commercial **CompuServe** Information Service in their Animal Forum [Go Petstwo] reptile/amphibian library section 6. Search by keyword "SSAR." On **America Online**, under "pet" section, search reptile files.

12–14 April 1996—Minton Symposium, Indiana Academy of Sciences, Indiana University/Purdue University Conference Center, Indianapolis, Indiana, USA. *Refer to meeting announcement in this issue for details.*

Mid-April 1996—2nd International Conference on the Biology and Conservation of the South Asian Amphibians and Reptiles, University of Peradeniya, Contact Anslem de Silva, Conference Director, Faculty of Medicine, University of Peradeniya, Sri Lanka. Tel. 94-08-88130. Fax 94-08-32572. *See meeting announcement below for further details.*

Second International Conference on the Biology and Conservation of the South Asian Amphibians and Reptiles

The Second International Conference, to be held in mid-April 1996, is being jointly organized by the University of Peradeniya/ Amphibian and Reptile Research Organization of Sri Lanka and the IUCN/SSC South Asian Reptile and Amphibian Specialist Group. The venue will be the University of Peradeniya, Sri Lanka.

The conference will provide a forum for presenting results of research on the herpetofauna of southern Asia. Other aims of the meeting are to form a panel for the coordination of research and conservation activities concerned with this fauna in the region, identify research priorities and a programme for the implementation of the IUCN/SC South Asian Reptile and Amphibian Specialist Group's Action Plan.

Two-day field trips (to Sinharaja World Heritage Site, Knuckles Biosphere Reserve, Peradeniya Botanical Gardens) will be arranged for participants.

For further details contact: *Anslem de Silva, Conference Director, Faculty of Medicine, University of Peradeniya, Sri Lanka. Tel. 94-08-88130; fax 94-08-32572* or (in India) *Indraneil Das, Chairman, IUCN/SSC South Asian Reptile and Amphibian Specialist Group, Centre for Herpetology, Madras Crocodile Bank Trust, Post Bag 4, Mamallapuram 603 104, India. Tel. +044 4124 46332.*

SYMPOSIUM IN HONOR OF DR. SHERMAN A. MINTON, JR.
12–14 April 1996, Indianapolis, Indiana

The Indiana Academy of Sciences is sponsoring a Symposium in April of 1996 in honor of **Sherman A. Minton, Jr**. on the occasion of the publication of his revision of the *Amphibians and Reptiles of Indiana*. The symposium will be held 12–14 April 1996 in Indianapolis at the Indiana University/Purdue University Conference Center. Dr. Minton is well known for his work on venomous reptiles, the reptiles of Pakistan, the regional herpetology of the midwest, and popular books on herpetology.

The Symposium will include a Friday evening (12 April) dinner featuring **Whit Gibbons** as the after dinner speaker. The morning program of the Saturday Conference (13 April) will focus on the career of Dr. Minton with talks by **Carl Gans** (Minton's work on the reptiles of Pakistan), **David Hardy** (pitviper bites), **Bernard Bechtel** (abnormalities in reptiles), and **Harold Voris** (venomous sea snakes). The afternoon session will focus on "Hoosier Herpetology" and the publication of Minton's revision of his classic monograph on the herpetofauna of Indiana; biologists working on the amphibians and reptiles of Indiana will present brief overviews of their research and provide a perspective on herpetological research in Indiana today. On Sunday (14 April) there will be optional field trips.

For registration information, contact: Harriet A. Rodenberg (Minton Conference), University Place, Conference Center and Hotel, 850 West Michigan Street, Indianapolis, Indiana 46202-5198, USA. Tel. 317-274-5053; Fax: 317-274-3878; e-mail: hrodenbe@indycms.iupui.edu.

CURRENT RESEARCH

The purpose of **Current Research** is to present basic summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA; e-mail: breckbarth@aol.com. Comments and suggestions are also welcome.

Freeze Tolerance

The physiology of freezing is discussed in two papers by Layne and Lee and colleagues. Five frog species were studied and found to tolerate temperatures as low as -8°C for at least two weeks. At the onset of freezing the liver produces high (to 100x normal) concentrations of glucose or glycerol. The water content of major organs is reduced by 50% and breathing, heart beat, and most other vital functions cease only to begin again with hours of thawing.

Layne, J. R., Jr and R. E. Lee, Jr. 1995. Adaptations of frogs to survive freezing. Climate Res. 5:53–59.

Costanzo, J. P., R. E. Lee Jr, A. L. DeVries, T. Wang, and J. R. Layne, Jr. 1995. Survival mechanisms of vertebrate ectotherms at subfreezing temperatures: applications in cryomedicine. FASEB J. 9:351–352.

Amphibian Conservation

During a 17-year study in England, Beebee found that spawning dates for three species of amphibians have become earlier. The date of first sighting for each species has also become earlier. Temperature at the breeding site has increased over the same time period and correlates with the breeding times.

Measures needed for the conservation of 13 Lesser Antillean anurans are discussed by Kaiser and Henderson. All of the islands have legislation which should protect these species if properly implemented.

In 1915, zoologists Joseph Grinnell and Tracy Storer conducted an intensive survey of amphibians (and other vertebrates) across a section of the central Sierra Nevada of California, including portions of Yosemite. Using historical collection data, some published in Grinnell and Storer's *Animal Life in the Yosemite* (1924. University of California Press) with other information taken from the surveyors' field notes, Drost and Fellers repeated the earlier survey in 1992. They found that all seven native frogs showed evidence of decline, with two species (*Rana aurora* and *R. boylii*)

virtually extirpated from this portion of their historical range. Even the widespread Pacific treefrog (*Pseudacris regilla*), a species not generally included in discussions of "declining amphibians," showed significantly reduced numbers at higher elevations.

Amphibian Taxonomy

Using 18 morphometric measures, Sinsch et al. reassess Peruvian frogs of the leptodactylid subfamily Telmatobiinae. Based on their analysis they recommend the recognition of two genera and six species rather than the present arrangement of three genera, six species, and nine subspecies.

SINSCH, U., A. W. SALAS, AND V. CANALES. 1995. Reassessment of central Peruvian Telmatobiinae (genera *Batrachophrynus* and *Telmatobius*). I. Morphometry and classification. Alytes 13(1):14–44.

Anuran Biology

A wide variety of topics are covered in a new book by Herrmann and Zimmermann (1994. Beiträge zur Biologie der Anuren [Contributions to the Biology of Anurans]. Tetra Verlag, Melle, Germany. 185 pp.). Although many of the chapters focus on anuran faunas and conservation, others discuss topics such as fossils and herpetoculture. Each chapter is in German with an English summary.

More on Manipulating Sex Ratios for Conservation

In response to Vogt's editorial on manipulating sex ratios as a conservation strategy, Mrosovsky and Godfrey point out additional data on the intersex hatchlings cited by Vogt and caution against changing management strategies without proper evaluation.

MROSOVSKY, N., AND M. H. GODFREY. 1995. Manipulating sex ratios: Turtle speed ahead! Chelonian Cons. Biol. 1(3):238–240.

Green Blood

Skinks of the genus *Prasinohaema*, endemic to New Guinea and adjacent islands, are unique in being the only amniotes with green blood. Austin and Jessing examined the blood of these lizards to determine the source for the green pigmentation and discovered that these lizards have 40 times the biliverdin concentration of humans with green jaundice.

AUSTIN, C. C., AND K. W. JESSING. 1994. Green-blood pigmentation in lizards. Comp. Biochem. Physiol. 190A(3):619–626

Geckos

In a series of papers, Seipp and colleagues describe two new geckos and *Rhacodactylus ciliatus* is redescribed after being rediscovered more than 100 years after it was originally described by Guichenot (1866).

Bauer and Russell test the hypothesis that frequency of tail loss is reduced in lizards with specialized tails. They found, however, that autotomy frequency was not correlated with tail specialization. Structural constraints imposed by paedomorphosis may effect autotomy frequency in gekkonids.

SEIPP, R. 1994. Eine neue Art der Gattung *Phelsuma* Gray 1825 aus Zentral-Madagascar (Reptilia: Sauria: Gekkonidae) [A new species of the genus *Phelsuma* Gray 1825 from central Madagascar]. Senckenbergiana Biologica 74(1/2):193–197.

Senckenbergiana Biologica 74(1/2):205–211.

BAUER, A. M., AND A. P. RUSSELL. 1994. Is autotomy frequency reduced in geckos with "actively functional" tails? Herpetol. Nat. Hist. 2(2):1–15.

Migration

Using genetic markers derived from mitochondrial DNA, Bowen and colleagues were able to trace the origin of juvenile loggerhead turtles (*Caretta caretta*) found in Baja California. Loggerheads are not known to nest along the Pacific coast of the Americas and it was determined that most of the juveniles were from nesting sites in Japan. As juveniles these turtles traverse approximately one-third of the planet.

Bowen, B. W., F. A. Abreu-Grobois, G. H. Balazs, N. Kamezaki, C. J. Limpus, and R. J. Ferl. 1995. Trans-Pacific migrations of the loggerhead turtle (*Caretta caretta*) demonstrated with mitochondrial DNA markers. Proc. Nat. Acad. Sci., USA 92:3731–3734.

Paleoherpetology

Wassersug and Wake describe two well-preserved tadpoles from the Middle Miocene of central Turkey. The tadpoles most closely resemble the genus *Pelobates*. Taxonomic and ecological considerations are discussed.

Parmley examined fossils of the snake *Lampropeltis intermedius* and determined that they belong to *Lampropeltis getula* and *Pituophis*. In light of these new data, the significance of *Lampropeltis similis* fossils are discussed.

Wassersug, R. J., and D. B. Wake. 1995. Fossil tadpoles from the Miocene of Turkey. Alytes 12(4):145–157.

Parmley, D. 1994. Reevaluation of the extinct kingsnake *Lampropeltis intermedius* Brattstrom (Colubridae) with comments on the ancestry of *Lampropeltis triangulum*. Herpetol. Nat. Hist. 2(2):83–88.

Biodiversity & Conservation

Biodiversity and conservation are the subjects of a new book on Mexican flora and fauna. Both phylogenetic uniqueness and endemism were considered in the development of the authors' recommendations. The book also offers a good summary of the Mexican herpetofauna.

Flores Villela, O., and P. Gerez. 1994. Biodiversidad y conservación en México: vertebrados, vegetación y uso del suelo. Universidad Nacional Autónoma de México, Ciudad Universitaria, México. 439 pp.

New Zealand Herpetology

Volume 21, number 4 of the *New Zealand Journal of Zoology* is a special issue consisting of 16 papers from the Second World Congress of Herpetology. The papers are divided into three sections: Reviews, Physiology, and Conservation. The contents of this volume are:

Daugherty, C. H., G. B. Patterson, and R. A. Hitchmough. 1994. Taxonomic and conservation review of New Zealand herpetofauna. 317–323.

Towns, D. R., and C. H. Daugherty. 1994. Patterns of range contractions and extinctions in the New Zealand herpetofauna following human colonisation. 325–339.

Bell, B. D. 1994. A review of the status of New Zealand *Leiopelma* species (Anura: Leiopelmatidae), including a summary of demographic studies in Coromandel and on Maud Island. 341–349.

Cree, A. 1994. Low annual reproductive output in female reptiles from New Zealand. 351–372.

SHIS Publications

The Smithsonian Herpetological Information Service (SHIS) series publishes papers judged useful to individuals interested in the biology of amphibians and reptiles, but which are unlikely to be published in journals. More information can be obtained by writing George Zug, Division of Amphibians and Reptiles, National Museum of National History, Smithsonian Institution, Washington, D.C. 20560, USA. The six papers published during 1994 are:

Vanzolini, P. E. 1994. On the distribution of certain South American turtles (Testudines: Testudidae & Chelidae). (97):1–10.

Auth, D. L. 1994. Checklist and bibliography of the amphibians and reptiles of Panama. (98):1–59.

Liner, E. A. 1994. Bibliography and scientific name index to amphibians and reptiles published in the Caribbean Journal of Science Volumes 1–25, 1961–1989. (99):1–30.

Kitchell, K., Jr. and H. A. Dundee. 1994. A trilogy on the Herpetology of Linnaeus's Systema Naturae X. (100):1–61.

Fruit and Nectar Feeding by *Podarcis lilfordi* (Lacertidae) on Cabrera Archipelago (Balearic Islands)

Although only about 2% of lizard species are strictly herbivorous, many others consume plant and animal material in variable proportions (e.g., Busack and Jaksic 1982; Heatwole and Taylor 1987; Iverson 1979; Pough 1973). Omnivorous lizards often prefer flowers and fruits over leaves, presumably because reproductive parts are more efficiently assimilated than vegetative parts (Durtsche 1992; Heatwole and Taylor 1987; Pough 1973).

Lizard nectarivory has only been described on islands, in species of the families Gekkonidae (from Seychelles: Cheke 1984; Evans and Evans 1980; Gardner 1986; from New Zealand: Whitaker 1987a, 1987b), Scincidae (from Seychelles: Cheke 1984), Teiidae (from Bonaire, Lesser Antilles: Dearing and Schall 1992) and Lacertidae (from Madeira: Elvers 1977, 1978). Most reports of frugivory also result from studies of insular populations: Racine and Downhower 1974; Christian et al. 1984; Schluter 1984 (Galapagos Islands); Barquin and De La Torre 1975; Valido and Nogales 1994 (Canary Islands); Sadek 1981 (Madeira and Salvages Islands); Iverson 1985 (Bahamas); Whitaker 1987a (New Zealand); Auffenberg 1988 (Philippines); Sylber 1988 (Gulf of California); Castilla and Bauwens 1991 (Columbretes Archipelago, Spain); and Dearing and Schall 1992; Lichtenbelt 1993 (Netherlands Antilles). Nevertheless, continental populations may be frugivorous (e.g., Hernández 1990; Traveset 1990).

Here we report our observations on herbivory in *Podarcis lilfordi* (Günther 1874), a small lacertid lizard (81 mm maximum SVL) endemic to the islands that surround Mallorca and Menorca, Balearic Islands, Spain. The few references on the diet of this lizard describe it as an insectivorous species, although mentioning flower and fruit consumption (Pérez-Mellado 1989; Salvador 1986). Mayol (1985) points out that these lizards also eat nectar, but he does not specify, however, whether such nectar is collected without consuming the flowers. Pérez-Mellado (1989) reports that *P. lilfordi* reaches the nectar of *Crithmum maritimum* (Umbelliferae) by consuming its stamens.

Our data are based upon direct observations of foraging lizards, made during the peak of their daily activity period, mostly from January through September, 1993, in the archipelago of Cabrera and on Moltona islet (south of Mallorca island). The vegetation of these islands is dominated by a Mediterranean scrubland. We followed some individual lizards or watched particular plant species, from a distance of 2–3 m, during 20 min or until the animals disappeared. For each observation period, we recorded the number of plant parts consumed with a hand counter, and timed the feeding behavior with a stopwatch. Some additional data were obtained by examining stomach contents (gathered using stomach flushing) and fecal samples (taken haphazardly from the ground), collected during 1992 and 1993.

In the flowering period (mid March–mid April) of *Euphorbia dendroides* (Euphorbiaceae), a highly branching shrub that can reach 2 m in height, *P. lilfordi* was observed climbing up the trunk or the lowest branches near the ground to reach the yellow insect-pollinated flowers. This plant produces hundreds to thousands of inflorescences, 5 mm in size, that are in turn assembled in umbels of one to five. Each inflorescence consists of several minute flow-

ers surrounded by 4–5 glands, which secrete a copious and highly concentrated nectar. We observed lizards up to 1.1 m above ground surface, moving from branch to branch with no difficulty. After finding an umbel, the lizard stops and, placing its snout in front of the glands, starts lapping up the nectar. The lizard usually feeds from all inflorescences of a whole umbel before moving to the next, usually nearest umbel. The feeding rate averaged 8.8 ± 7.3 (SD) lapped inflorescences/minute (N = 10 individuals; total time spent on plants 109 min). Not all visited inflorescences are lapped, which suggests that lizards are examining and selecting those richer in nectar. The period that an individual lizard remained in a shrub varied from several seconds to 18 min (N = 16 individuals). Up to five individuals were counted simultaneously feeding on a single shrub, which is equivalent to 2.4 lizards/m^2 of cover (N = 9 plants observed). Nectar feeding was observed with greatest frequency on sunny days (with a photoperiod length of 12 hours) between 0800 h (1.5 hours after local sunrise) and 1100 h (GMT), although some individuals were seen on inflorescences until mid-afternoon.

When feeding upon nectar of *E. dendroides*, the lizard rubs its snout against the anthers that jut out from the male flowers. Also, while moving among inflorescences within the shrub, the ventral part of its body brushes against both male and female flowers, with the possibility of laying the collected pollen from males on the stigmas of females, and thus favoring pollination. This is supported by our direct observations (with binoculars) of several individuals with the snout covered by pollen while they were feeding upon nectar.

Podarcis lilfordi was also observed feeding upon nectar of *Rosmarinus officinalis* (Labiatae), a shrub widely distributed in Cabrera that blooms during winter. Its bluish insect-pollinated flowers are about 8 mm long, located in racemes at the distal ends of the branches, and produce abundant nectar. Up to six individual lizards were counted under a shrub about 1 m in diameter. Lizards concentrate under the shrubs not only to eat but also for refuge since the stems are multi-branched and densely foliaged. To reach the nectar, *P. lilfordi* introduces the tip of its snout into the tube of the corolla and, extending its tongue, starts lapping from the bottom. As in the case of *E. dendroides*, lizards do not feed from all flowers visited.

The particular arrangement of the floral pieces of *R. officinalis* allows also that while the lizard is lapping up nectar, the stigma and the anthers come in contact with the upper part of its head. If some of the pollen grains adhere to the head, it is quite possible that the lizard promotes pollination in this plant.

Lizards feed not only upon the nectar of *R. officinalis*, but also consume its flowers. They can ingest entire flowers or just bite a piece of the corolla, often taking stamens and the pistil with it. They have also been observed removing dropped flowers. The examination of stomach contents reveals that during February and March, the flowers of *R. officinalis* constitute, on average, 70 ± 35% (SD) of stomach content volume (N = 15). The flowers of *E. dendroides* were never observed to be consumed by lizards, probably because of the toxic latex that the plant exudes when tissue breaks.

Another species from which flowers are abundantly consumed in Cabrera, though never reaching the importance of *R. officinalis*, is *Globularia alypum* (Globulariaceae), a short shrub with small violet flowers arranged in capitula of about 15 mm diameter. From January to March, lizards were observed climbing with some difficulty, the thin (ca. 1 mm thick) branches which bent under the weight of the animals. While climbing, they appeared to maintain balance with the aid of their tails. Some lizards were observed jumping from the ground to reach the flowers. They usually tore off the stamens, pistils, bracts, and petals, leaving some capitula almost completely bare of functional flowers.

Six individuals were also seen, in January, tearing off and ingesting the petals of the yellow flowers of *Fumana ericoides* (Cistaceae), a plant sparsely distributed in Cabrera. At the beginning of September, on Na Plana, one of the islets of the Cabrera archipelago, the majority of individuals of *P. lilfordi* were observed on the branches of *Arthrocnemum fruticosum* (Chenopodiaceae) ripping the stamens from the flowers. Flowers from other species, such as *Alyssum maritimum* (Brassicaceae) and *Cneorum tricoccon* (Cneoraceae) also have been occasionally found in stomach contents.

Analysis of about 350 lizard scats of *P. lilfordi* from the Cabrera archipelago showed that it consumes the fleshy fruits of a variety of species (Table 1). The prevalence in the diet of a particular species was dependent on the fruit availability in the place and time of the collection of the samples. With the exception of *C. tricoccon*, which appears to be dispersed mainly by lizards on Cabrera, these fleshy fruits are also consumed by birds (Traveset 1993). The fruits of *C. tricoccon* are available from late winter through late spring and are consumed by lizards as soon as they ripen (turning a red color). Lizards were often seen climbing the shrubs—which can reach up to 1 m in height—and removing the cocci (three per fruit), one at a time. Usually, the lizard takes a coccus in the mouth and transports it some distance from the plant, where it is swallowed. We found up to four seeds of this plant in lizard scats, although two or three is usual. The seeds have been shown to be viable after passing through the lizard's gut, using the TTC (2,3,5 triphenyl tetrazolium chloride) bioindicator (Heydecker 1968).

TABLE 1. Plant species consumed by *Podarcis lilfordi*. N = nectar, Fw = flowers, Fr = fruits.

Plant species (Family)	N	Fw	Fr
Juniperus phoenicea (Cupressaceae)			+
Ephedra fragilis (Ephedraceae)			+
Ficus carica (Moraceae)			+
Arthrocnemum fruticosum (Chenopodiaceae)		+	
Fumana ericoides (Cistaceae)		+	
Alyssum maritimum (Brassicaceae)		+	
Euphorbia dendroides (Euphorbiaceae)	+		
Rhamnus ludovici-salvatoris (Rhamnaceae)			+
Pistacia lentiscus (Anacardiaceae)			+
Cneorum tricoccon (Cneoraceae)		+	+
Withania frutescens (Solanaceae)			+
Rosmarinus officinalis (Labiatae)	+	+	
Phillyrea angustifolia (Oleaceae)			+
Phillyrea latifolia (Oleaceae)			+
Globularia alypum (Globulariaceae)		+	
Arum italicum s.l. (Araceae) *			+
Asparagus stipularis (Liliaceae)			+

* This species has only been found on Moltona islet.

Preliminary analyses of stomach contents and observations of foraging behavior in *P. lilfordi* reveal that the degree of herbivory varies with season. During February and March plant material constitutes 70 ± 35% (SD) of the volume of stomach contents,

and appears in 93% of stomachs (N = 15). Percentages decrease to 3 ± 7% and 13%, respectively, in stomach contents examined from specimens (N = 15) captured during August.

Our observations indicate that plant material constitutes an important fraction of the diet of *Podarcis lilfordi* during some months of the year at some localities. *P. lilfordi* consumes flowers and fruits of different plant species, and probably acts as seed dispersers for them. It also obtains nectar of several species by lapping the flowers without ingesting or damaging them. This indicates that, at least for species such as *Euphorbia dendroides* and *R. officinalis*, the lizard may have a role as pollinator. Such a role has been proposed for another lacertid, *Podarcis muralis dugesii* (Elvers 1977, 1978), and for three species of geckos (Whitaker 1987a, 1987b). According to Elvers (1977), the smooth texture of the skin of most lizards would make them inefficient collectors and transporters of pollen. Our observations, however, indicate that body contact with the sticky nectar while visiting the flowers increases pollen adherence to the skin.

We conclude that *P. lilfordi* has the potential of having a relevant effect on the reproduction of several plant species. Besides influencing plant fitness, either positively (pollinating flowers or dispersing seeds) or negatively (consuming flowers, partially or totally), the lizards may well affect the vegetation structure of the island to some degree, especially at those sites where they are most abundant.

Acknowledgments.—We are grateful to the staff of the National Park of Cabrera for providing logistical help. Financial support came from DGICYT grant PB91-0055 and from ICONA. Xavier Campillo was very efficient in getting us the literature needed. We also thank S. D. Busack, R. W. Hansen, and an anonymous reviewer for their helpful comments on the manuscript.

Status of *Leptodactylus labyrinthicus* (Calf Frog, Rana Ternero) in Venezuela

Since the publication of Rivero's "Salientia of Venezuela" (1961), the identification and distribution of the different members of the *Leptodactylus pentadactylus* species group in Venezuela has been puzzling. The group, composed of 11 species (Heyer 1979), ranges from Honduras to the Guianas, reaching Peru and Argentina through the Amazonian region. No member of the species group is present in Chile (Veloso and Navarro 1988).

Prior to Heyer's (1979) study of the systematics and distribution of the *L. pentadactylus* species group, *L. pentadactylus* was the only large species of the group recorded from Venezuela. In 1961, Rivero received some specimens collected by Maquiritare Indians in the vicinity of the Río Cunucunuma, Estado Amazonas, close to the border with Brazil and Colombia in the southernmost part of the country. This information was reported later in a review of the distribution of frogs in the Venezuelan Guayana (Rivero 1964b). Subsequently, Heatwole et al. (1965) reported collecting one specimen in the area south of El Dorado, Estado Bolívar; Rivero and Esteves (1969) found a fairly large population in Güiria, Estado Sucre; and Rivero-Blanco and Dixon (1979) reported its presence in Yuruani, Estado Bolívar.

In August 1991, we were surveying frogs in the state of Sucre in northwestern Venezuela. On 16 August 1991, while a late afternoon rain was falling, we found a population of large frogs similar to *L. pentadactylus* (Fig. 1), at La Fragua (10°12'N; 63°57'W, ca. 350 m), a village in one of the valleys running down from the northern versant of the Sierra del Turimiquire (Fig. 2). Males began calling at about 1730 h and stopped at 2000 h. Occasionally, automobiles pass this site on the road to Cumanacoa. All large trees have been cut, and the most common habitat is secondary growth of mixed riparian and thorny forests. The frogs appeared only slightly disturbed by our presence, even when flushed with lantern light. Approximately five males were calling louder than others in the background. They were under rocks, in crevices, or among dense herbs about 45–60 cm high. Some adult specimens were collected along the bank of a temporary stream, parallel to the small Río La Fragua, one of the tributaries of the larger Río Manzanares. We were informed that people in the village do not include the frogs as part of their diet. *Bufo granulosus*, *B. marinus*, *Leptodactylus wagneri*, *Physalaemus pustulosus*, and *Hyla crepitans* also make up the anuran community.

FIG. 1. Male *Leptodactylus labyrinthicus* from La Fragua, Estado Sucre, Venezuela, showing the chest spines grown during the reproductive season.

Three specimens were collected—two males and one female. One male was immediately preserved for deposition in the Collection of Vertebrates, Universidad de Los Andes (CV-ULA 5541). The other two frogs were transported alive to Mérida, but during the trip, the male ate the female. That male was kept alive until mid-July 1992; after its death, unfortunately, the carcass was discarded. Figure 1 shows one of the collected mature male specimens with chest spines.

On 19 August 1991, we arrived at Macuro (10°40'N; 61°02'W, about 10 m), in the easternmost sector of the Península de Paria National Park, Estado Sucre (Fig. 2). This point is a flat terrace extending for some 300 m to the piedmont of a chain of hills, covered with tropical humid forests (Petróleos de Venezuela, S. A. 1992). The island of Trinidad is within view. That night five different species of frogs were heard calling, including one with apparently the same call as the one at La Fragua. At mid-afternoon on the following day, an extremely heavy rain fell while we were climbing the mountains. Before sunset, at the piedmont (between 50 and 100 m) another population with the same call was located. No specimens were collected but notes were taken. More than 20 males were identified by their calls while coming down the trail along Macuro Creek. Each calling male was separated from its nearest neighbor by a mean distance of about 10 m. The habitat was tropical rain forest with large trees and agricultural clearings. Some of the calling frogs were no more than 20 m from houses and domestic animals. *Bufo granulosus*, *B. marinus*, *Colostethus trinitatis*, *Eleutherodactylus* sp., *Leptodactylus fuscus*, and *Physalaemus* aff. *pustulosus* were also recorded.

On 1–2 November 1993, the senior author revisited the La Fragua locality to check for the population of large frogs. At that time, no major environmental changes were noted. There was a light rain every evening, but frog activity was low. Only *Hyla crepitans* was heard calling. By playing a tape of calls of the large *Leptodactylus* species recorded at the same place two years before, several responses from individuals of the desired species were obtained—isolated calls from different sites. Only a few individuals could be seen. Three specimens were collected and preserved (CV-ULA 5620–22). The docile and submissive behavior shown by these large frogs was noteworthy.

The frogs collected were similar to two specimens (CV-ULA 1179–80) of large *Leptodactylus* from Cueva del Agua, 600 m, Estado Anzoátegui, received by the Vertebrate Collection of the Universidad de Los Andes in July 1979. Cueva del Agua is about 100 km W of La Fragua (Fig. 2).

Three large species of *Leptodactylus* might occur in Venezuela: *L. knudseni*, *L. labyrinthicus*, and *L. pentadactylus* (Péfaur

FIG. 2. Distribution of *Leptodactylus labyrinthicus* in Venezuela, showing populations reported here (stars), by Heyer (1979) (squares); and by Rivero and Esteves (1969) (triangle).

1992). Using Heyer's (1979) key for the members of the *L. pentadactylus* group and Hero and Galatti's (1990) characteristics for a pair of species of this same group, and on distributional grounds, we have identified our specimens as *Leptodactylus labyrinthicus*. This identification was confirmed by Heyer upon his examination of the specimens (Heyer, pers. comm.). Based on distributional inferences (Heyer 1979) it is probable that the specimens reported by Rivero (1961), Heatwole et al. (1965), and Rivero-Blanco and Dixon (1979) are *L. knudseni*, but those collected by Rivero and Esteves (1969) are *L. labyrinthicus*.

The populations of *L. labyrinthicus* reported here confirm the presence of this species in Venezuela north of the Río Orinoco in tropical humid forest or previously forested environments of the eastern part of the country (Fig. 2). However, there still remains the question of why this species is not present in the tropical humid forest environments of north-central and northwestern Venezuela. Members of this species are distinct and ubiquitous where present. During the reproductive season (Rivero and Esteves 1969; and our data), its loud and peculiar call, similar to the bleat of a calf, large size, and predatory behavior make it impossible to overlook. Several thorough herpetological studies of Venezuelan tropical forests and savannahs failed to detect this species, although a wide range of habitats were sampled. Studies conducted in forested environments (Cordero 1987; Rivero 1964a) in the Coastal Range and associated habitats did not report this species. Among the savannah studies, one was conducted in the eastern part of Venezuela, south of the Río Orinoco (Hoogmoed and Gorzula 1979), while others were north of the Río Orinoco, three in the Central Llanos (Fouquette 1968; Lamotte and Solano 1989; Staton and Dixon 1977), and one in the Upper or Western Llanos (Péfaur and Díaz de Pascual 1987). None included this species in their accounts.

Some important biogeographical and ecological facts about *L. labyrinthicus* should be noted: (1) Its general distribution in eastern Venezuela is not continuous; populations are restricted in their distribution and confined to Sucre and the northern part of Anzoátegui and Monagas states. (2) At least in the past, the Río Orinoco and/or the Guyana Shield environments have not been zoogeographical barriers for the species, as it exists north of that river (in Venezuela), and south of the shield (in Roraima State, Brazil) (Heyer 1979: MZUSP 24936). Continuity of the tropical humid forest persists (Huber and Alarcón 1988), potentially permitting a distribution throughout those environments. However, the geographical distance between the northeastern Venezuelan (about 11°N) and northern Brazilian (about 5°N) populations, plus the existence of a complex of geological and floristic factors in the intermediate environment, allow the prediction of taxonomic differentiation between the northern and southern populations at least at the level of subspecies. (3) The distributional hiatus between these two populations of *L. labyrinthicus* is seemingly occupied by populations of *L. knudseni*. (4) Although the species occurs primarily in tropical humid forests, it also can be found in areas of drier secondary forests. (4) The Llanos, or savannahs, are not suitable habitats for *L. labyrinthicus*.

At present, in both Brazil and Venezuela, there are some experimental commercial frog farms using what we are here calling *L. labyrinthicus*. From a conservation point of view, these attempts at exploitation could become a problem in Venezuela: (1) these frogs are economically attractive because of their large size; (2) they are easy to collect due to their behavior (loud call and docility); (3) it is hard to differentiate between *L. knudseni* and *L. pentadactylus*; and (4) they are distributed only in a small sector of the country. These factors could easily lead to the decimation of the populations by over collecting. At this time, our knowledge of *L. labyrinthicus* biology is too meager to be confident that the management of commercial farms will be adequate.

Acknowledgments.—We thank the CDCHT–Universidad de Los Andes (Project TC-02-91/93) and the Fundación Fauna Andina for financing a project to survey the herpetofauna of northern Venezuela. CONICIT Project PI-011 permitted interchange of information between the Brazilian University of Campinas Herpetological Collection and the Venezuelan Universidad de Los Andes Herpetological Collection. We acknowledge Nelson Díaz, Faculty of Science, Universidad de Chile, for sending specimens he collected in Venezuela. We thank W. R. Heyer for confirmation of specimen identifications. Comments made by J. E. Simmons, A. J. Cardoso, and two anonymous reviewers are highly appreciated. The map was prepared by Leida Valero.

New Records of Dicephalic Snakes in Museum Collections

The first review of two-headed snakes by Cunningham (1937) surveyed 48 taxa, while the latest review of the subject by Smith and Pérez-Higareda (1988) added another 51 taxa for a total of 99 species and subspecies known to have duplication in some part of the body. This note reports the presence of 11 additional specimens, including the first records for one (or possibly two) species, in the California Academy of Sciences (CAS) *(Lampropeltis getulus californiae, Pituophis catenifer catenifer, Thamnophis atratus atratus, Thamnophis* cf. *gigas),* the Museum of Comparative Zoology (MCZ) *(Coluber constrictor, Elaphe obsoleta, Thamnophis sirtalis sirtalis, Bothrops atrox),* and Brigham Young University (BYU) *(Thamnophis elegans vagrans).* Abbreviations used include SVL (snout-vent length), TL (tail length), MBD (midbody diameter), RTL (relative tail length), SL (supralabials), N (nasal: undivided=1, semidivided=1/2, divided=2), L (loreal), PRO (preocular), PTO (postoculars), SO (subocular), T (temporals), IL (infralabials), AG (anterior genials), PG (posterior genials), G (gulars), DSR (dorsal scale rows), V (ventrals: divided=div.), SC (subcaudals: single=sin., paired=pr.), USVI (umbilical scar-vent interval), and VT (vertebrae).

The most publicized dicephalic snake is probably *Lampropeltis getulus californiae,* four of which were kept at the San Diego Zoo over a 20-year period from 1954–1974 (Chapman 1960; Lüdicke 1964; Schmidt and Inger 1957; Shaw 1955, 1956, 1958, 1959, 1968, 1971; Shaw and Campbell 1974; Wexo 1981a-b, 1987, 1992). Dudley Duplex I and Nip and Tuck exhibited the ringed phase pattern while Dudley Duplex II and an unnamed specimen that survived only a short time in captivity represented the striped phase. A fifth specimen (ringed phase) was reported by Belfit and Nienaber (1983). Two ringed-phase specimens, representing the sixth and seventh records for *L. g. californiae,* are preserved in the collection of the CAS. CAS 195591, from North Bay, Santa Rosa, Sonoma Co., California, is a 305-mm craniodichotomous juvenile with the following characteristics: 25.5 + 7 body and tail rings, SVL 259 mm, TL 46 mm, RTL 15.1%, 220 V, A 1, 56 pr. SC (#2-4 sin.), 23-23-19 DSR, 7 SL(#3-4 in orbit), N 2, 1 L, 1 PRO, 2 PTO, 2+3 T, USVI 17.7% V. Both heads are rotated laterally and joined at the angle of the jaw. The only cephalic scale variation involves the IL, which number 9 (first 4 contacting AG) on both sides of the right head while the left head possesses 9(4) on the left side and 10(4) on the right side.

CAS 195590, collected in 1984 on the Stanford University campus, Palo Alto, Santa Clara Co., California, is a 751-mm prodichotomous *L. g. californiae* with 24 + 6 body and tail rings, SVL 648 mm, TL 103 mm, RTL 13.7%, 223 V, A 1, 57 pr. SC, 21-23-19 DSR, 7(3,4) SL, N 2, 1 L, 1 PRO, 2 PTO, 2+3 T, and USVI 13.0% V. The left head has 8(3) IL on both sides but the right head exhibits 10(4) IL on the left side and 8(3) IL on the right. The specimen is eviscerated but the respiratory system was duplicated as two avascular tracheae are present, with vascular parenchyma of the right lung observable posteriorly and a left orifice lacking, confirming that the specimen had two separate tracheae (and therefore two right lungs as well), a terminal tracheal entry into the right lung, and lack of both a tracheal lung and left lung complex. Normal specimens of *L. g. californiae* possess a terminal tracheal entry and lack both a tracheal lung and left lung (pers. obs.).

Records of dicephalic *Pituophis catenifer* include Wright (1878) from San Jose, California, and Arefare (1892) from Auburn, California. Cunningham (1937) suspected that this latter specimen was the same one present in the CAS collection and which appeared in the San Francisco Examiner of 8 October 1891. A remarkable specimen is a craniodichotomous adult *P. c. catenifer,* representing either the third or fourth record for this subspecies, now in the collection of the CAS. CAS 195593 was collected as a hatchling in 1969 in Napa Co., California, resided in a local school for five years, and then was exhibited at the Steinhart Aquarium at the CAS until its death on 31 January 1991. Based upon a hatching period from September to November, it lived for 22 years plus 2-4 months, constituting a longevity record for both dicephalic snakes and this subspecies (Snider and Bowler 1992). This specimen is now represented by cleared-and-stained heads and a short neck section. The bifurcation of the spine has 6 VT on the left and 6 VT on the right, followed by 12 anteroposterioly compressed VT and then 20 normal VT. The first ribs appear on the VT 3. This snake is illustrated Leetz (1983, 1991) as well as several newspaper articles over the years and the current CAS visitor's brochure.

Dicephalic *Thamnophis atratus* have not been previously reported. CAS 195592 is a 234-mm craniodichotomous juvenile *T. a. atratus,* collected by Marianne Schonfisch on a road around "Windy Hill," Palo Alto, Santa Clara Co., California, with the following data: SVL 185.5 mm, TL 48.5 mm, RTL 20.7%, 153 V, A 1, 80 pr. SC, 19-19-15 DSR, N 1/2, 1 L, 1 PRO, 3 PTO, 10(5) IL, and USVI 17.0% V. Head shield variation includes 8(4,5) SL on both sides of right head but left head exhibits 8(4,5) SL on left and 7(3,4) SL on right side, 1+2+2 T on left side and 1+2+2/1 T on right side of right head while the left head possesses 1+2+1 T on left side and 1+2+2 T on right side. The gray vertebral stripes of each neck fuse at the level of V 27.

CAS 156520 is a 200-mm prodichotomous juvenile *Thamnophis* cf. *gigas* collected by Ed Ruman et al. in August, 1983, on Michigan Bar Road, Sloughhouse, Cosumnes River, Sacramento Co., California. This cleared-and-stained specimen was originally catalogued as a *Thamnophis atratus aquaticus* but that species is coastal in distribution and does not occur anywhere near the reported place of collection. Segmental counts and relative tail length fall within the range of variation of male *T. gigas* from the Sacramento area (Rossman and Stewart 1987) although this specimen could possibly be a female *T. e. elegans* or a *T. sirtalis fitchi* with high ventral and low subcaudal counts. Based upon its original identification and data, it is more likely to represent *T. gigas* than *T. sirtalis,* and if so would represent the first record for the species. It possesses the following characteristics: SVL 154 mm, TL 46 mm (tip missing), RTL ca. 23%, left and right neck bifurcations each with 11 VT, 168 total precloacal VT, 75 caudal VT, first ribs on VT 4 of each neck, 4 lympapophyses, 243 total VT (counting only one neck).

The first dicephalic *Thamnophis s. sirtalis* was reported by Ditmars (1903) and many subsequent individuals have been re-

ported (Cunningham 1937). Two neonate specimens of *T. s. sirtalis* in the MCZ were collected by Scott Heimo in August, 1962, near Westminster, Worcester Co., Massachusetts, both presumably from the same mother. MCZ 68959 is a 156-mm craniodichotomous individual in which the head is only partially duplicated, there being two snouts with 4 N, 4 L, 4 internasals, 5 prefrontals, one triradiate frontal, and a pair of normal parietals. Other characteristics include: SVL 121 mm, MBD 3.5 mm, TL 35 mm, RTL 22.4%, 19-19-17 DSR, 3 G, 159 V (#8-9 divided), A 1, 74 pr. SC, SL 7(3,4), N 2, 1 L, 1 PRO, 3 PTO, 1+2 T on left side, 1/2 T on right side, IL 10(5), USVI 14.4% V (V 137 still open). Only two maxillae are present, one on each of the outer lateral sides of the head. The medial sides of each snout exhibit 4 SL.

MCZ 68960 is a 109-mm amphidichotomous *T. s. sirtalis* in which the two heads are not completely separated but the posterior 2/3 of the body is bifurcated (the vertebral column appears to be duplicated along its entire length). It possesses N 2, 1 L, 1 PRO, 3 PTO, 1+2 T, and 2 AG on each side of the head, and 19-19-17 DSR. Variable scale counts include: 146 V (#61-92 div.) and 59 pr. SC (#6-10 and 44-52 sin.)/ca. 140 V (#51-80 div.) and 59 pr. SC, left/right lateral head counts include 8(4,5,6)/7(3,4) SL and 9(4)/8(4) IL, and left/right medial head counts include 6(3,4)/4 SL, 5 (4)/4(4) IL, and 1+1/1 T. There are three PG as both heads share a single curved genial contacting the medial AG of each side. The undivided anterior portion of the body plus the head measures 30 mm with the left body and tail 46 mm + 26 mm and the right body and tail 54 mm + 25 mm. Total length of the left/right sides are 102/109 mm with RTL 25.5%/22.9%.

A dicephalic *Elaphe obsoleta confinis* was reported by Strecker (1926). MCZ 176975 is a 196-mm embryonic craniodichotomous *E. obsoleta*, without locality data, donated by Rick Stafford in 1975. The two heads are nearly complete but joined at the tertiary temporals and last supralabials. Characteristics include: 34.5 + 14 dark rhombs on the body and tail, SVL 161 mm, MBD 5 mm, TL 35 mm, RTL 17.9%, 30-27-19 DSR, 230 V (#3-6, 14-31, 40-41, 43-44, 50-51, 85-86 div.), A 2, 64 pr. SC, N 2, 1 L, 1 PRO, 2 PTO, 10(4) IL, 3 G, USVI 23.2% V. Variable scale counts include: 9(4,5)/7(4,5) SL and 2+3+4 T on the left head (measuring 11 mm) and 9(3,4,5)/8(4,5) SL and 2+3+3 T on the right head (12 mm).

The first record of a dicephalic *Coluber constrictor* was that of Mitchill (1826). A gravid 1.3 m *C. constrictor* collected in Rockport, Essex Co., Massachusetts, by Rick Roth on 14 June 1994 laid a clutch of 18 small eggs (ca. 30 x 22 mm) on 19 June. Sixteen eggs hatched between 6-10 August but the two remaining eggs, which failed to hatch after another 10 days, contained a dicephalic specimen in one and a pair of perfectly formed twins in the other. MCZ 179700 is a craniodichotomous individual that has the two heads joined at the angle of the jaw and the body is folded back upon itself and fused together in three places. It has the following characteristics: SVL ca. 193 mm, TL 70 mm, RTL ca. 27%, 193 V, A 2, 103 pr. SC, 18-16-14 DSR, N 2, 1 L, 2 PRO, 2 PTO, and 3 G. Variable characters include 8(4,5)/7(3,4) SL on left head, 7(3,4)/8(4,5) SL on right head, 9(4) IL on left head, 10(4) IL on right head, 2+2/1+2 T on left head (both sides), and 2+2+2/2+1+2 T on right head. The dorsal scale rows are noteworthy as they are perfectly formed and not unusual in any way except in being even numbered. The twins (MCZ 179701–02), which are apparently females as everted hemipenes are absent, are identical in the following features: 99 pr. SC, 17-17-15 DSR, 7(3,4) SL, 9(4) IL, N 2, 1 L, 2 PRO, 2 PTO, 2+1+1 T on left side, 2+1+2 T on right side. Variable characteristics include (MCZ 179701 first, followed parenthetically by MCZ 179702): SVL 175 (171) mm, TL 58 (55) mm, RTL 24.9% (24.3%), 5 (4) G, V 179 (180), USVI 14% (16%). Total number of VT appears to be the same as G+V+SC count=283.

An uncatalogued photograph in the MCZ depicts a craniodichotomous *Thamnophis sirtalis sirtalis* collected at Saugus, Essex Co., Massachusetts from August-September, 1939, by Arthur Holbrook, Sr. Disposition of the specimen is unknown as it was never entered into the MCZ collection.

Numerous dicephalic *Bothrops atrox* have been reported, the first by Cunningham (1932). MCZ 14103 is a 247-mm asymmetrically prodichotomous *B. atrox*, without locality data, from the New York Zoo, donated by Thomas Barbour in 1920. Both heads measure 18 mm but the right head and neck (48 mm) are 27% longer than the left (35 mm). Other characteristics include: SVL 206 mm, MBD 11 mm, TL 41 mm, RTL 16.6%, 25-27-21 DSR, 179 V on body (#40-42, 46-57, 62-63, 79-80, 86-110 div.), 7 V and 2 G on the left neck (= 186 total V) and 19 V and 2 G on the right neck (= 198 total V), A 1, 62 pr. SC (#1, 3-21, 23-25 sin.), 7 SL (#2 entering pit), N 2, 2 PRO, 1 SO, one row of oculolabials, 6 intersupraoculars, 10(3) IL, and USVI 34.1% V. The only variable feature of scutellation is 3/2 PTO on the left head and 2/2 PTO on the right. The left paravertebral scale row is transversely enlarged four times the width of the costal scales for nearly the length of the body.

The first dicephalic *Thamnophis elegans vagrans* was reported by Cunningham (1937). A second specimen is represented by a 180–200 mm freeze-dried prodichotomous juvenile on exhibit in the Monte L. Bean Museum at BYU. This specimen was collected by Tim Gibson on 9 August 1981 at Orem, Utah, and exhibits an asymmetrical bifurcation of the necks with the left neck divided for 1.5 head lengths and the right neck for 2 head lengths.

Acknowledgments.—I wish to acknowledge Jens V. Vindum (CAS) and José P. Rosado (MCZ) for their assistance and cooperation in the examination of the specimens reported here. Thanks are due to Rick Stafford and Rick Roth for their consideration in donating their two-headed snakes to the MCZ. Lastly, Robert Hansen's careful editing of this note spotted the incorrect identification of CAS 156520 and I thank him for bringing it to my attention.

Ecological Observations of the Scincid Lizard *Mabuya agilis* in a Brazilian Restinga Habitat

Scincid lizards of the genus *Mabuya* are common in tropical regions and widespread in South America. About twelve species of this genus (out of 85) are found in Brazil (Peters and Donoso-Barros 1970), occurring in all Brazilian ecosystems. Relatively few ecological studies have been conducted for Brazilian species of *Mabuya* (e.g., Rebouças-Spieker 1974; Vanzolini and Rebouças-Spieker 1973, 1976; Vitt 1991; Vitt and Blackburn 1991; Vrcibradic and Rocha, ms. submitted); hence, their ecology is in general, poorly known.

Mabuya agilis is a small lizard (60–70 mm SVL) that inhabits open coastal habitats common in southeastern Brazil (Araujo 1984; Vrcibradic and Rocha, ms. submitted). In Linhares, southeastern Brazil (see below), *M. agilis* inhabits "restinga" habitats, occurring in grass tufts or near the base of shrubs and bromeliads (pers. obs.). Restingas are coastal Quaternary sand dune habitats covered with sparse herbaceous and shrubby vegetation (Suguio and Tessler 1984). In spite of its relative abundance in the area, this species has relatively reclusive habits, compared to sympatric lizard species (e.g., *Tropidurus torquatus*, *Cnemidophorus ocellifer*, *Ameiva ameiva*) (Bergallo and Rocha 1993, 1994).

Study Area.—In this study, we present data on food habits, thermal biology and activity of *Mabuya agilis* in Linhares. Field work was carried out in a "restinga" habitat (locally called "Nativo") in the Reserva Florestal Vale do Rio Doce (19°18'S, 40°19'W), Linhares municipality, Espirito Santo, southeastern Brazil. The elevation in the reserve varies between 30 and 60 m. The climate is wet and warm, with annual rainfall of 1300 mm and mean annual temperature of 23°C (Jesus 1988). This study was conducted in July 1993, during the dry season.

Methods.—We made observations in the field from 0630 to 1800 h. Lizards were collected in the course of 13 days using five pitfall traps provided with 10 m drift fences. We visited the pitfalls regularly (at half-hour intervals) and checked for the presence of lizards. In addition, we walked along a trail in the restinga looking for lizards. When a lizard was sighted the hour of activity was recorded and an attempt was made to capture it by hand. Whenever we failed such an attempt and the lizard moved to the interior of a thicket of grass, we rapidly established a pitfall trap with fences near the thicket. Then, we kicked at the grass thickets to startle the lizard and drove it to the pitfall trap. We also sometimes used a rifle to improve lizard collecting. Each lizard's cloacal temperature was recorded (to the nearest 0.2°C) using a Schultheis quick-reading cloacal thermometer. For thermal biology purposes we only considered those lizards collected by rifle or those dislodged from grass tufts and driven to the pitfalls, if temperature measurement was made within 30 s from the first observation. The temperatures of the air (1 cm above ground) and substrate where each lizard was first sighted were also recorded. For lizards found inside the pitfalls, temperatures were not considered. The hour at which each lizard was active at the time of its first sighting was also recorded. The mean activity temperature of *M. agilis* was estimated as the mean average of the body temperatures of active lizards (Brattstrom 1965). Variation in body temperature throughout the day was estimated by averaging the body temperatures within each hour interval. Air and substrate temperatures within each hour interval were also averaged for comparisons with the lizards' daily variation in body temperature. The relationship between body temperature and air and substrate temperatures, respectively, were analyzed by regression analyses and multiple regression (Zar 1974).

The stomach contents of 18 *M. agilis* were analyzed and identified to order. For each lizard we counted the number of prey of each type and each item was measured with a Vernier caliper (to the nearest 0.1 mm) and its volume (in mm^3) was estimated by multiplying its three dimensions (length, width, and depth; Schoener 1967). Diet composition was then described in terms of number and volume of each prey type in the sample, and of frequency, defined as the number of lizard stomachs containing each prey type.

Activity.—*Mabuya agilis* was active between 0800 and 1700 h and had a unimodal activity pattern, with a peak between 0900 and 1100 h (Fig. 1). This activity pattern (including peak and extension) is similar to that of other species of this genus in different areas of Brazil (Vitt 1991; Vitt and Blackburn 1991; Vrcibradic and Rocha, ms. submitted). An extensive activity period for lizards of the genus *Mabuya* has also been demonstrated to occur in other continents (e.g., Huey and Pianka 1977).

Thermal Biology.—Body temperatures of *M. agilis* ranged from 25.0°C to 36.4°C with a mean activity temperature of 31.4 ± 3.1 SD (N = 24). Highest body temperatures were recorded between 1400 and 1500 h (mean = 34.5 ± 1.8 SD, N = 2) and the lowest between 1600 and 1700 h (mean = 25.8 ± 1.1 SD, N = 2) (Fig. 2), when the lizards retreat to shelter. The decline of the mean temperatures (air, substrate, and body) observed between 1200 and 1300 is due to cloud cover during that time period on both days on which those particular data were obtained. Body temperature was significantly correlated to both air temperature ($r = 0.90$, $p <$

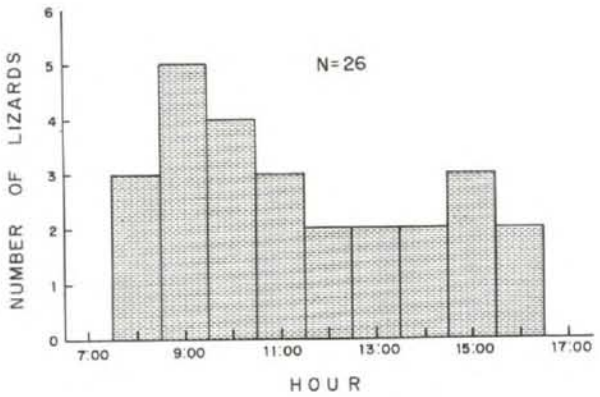

FIG. 1. Activity of *Mabuya agilis* in the Nativo of Linhares, Espirito Santo.

0.001, N = 24) and substrate temperature ($r = 0.68$, $p < 0.001$, N = 22) (Fig. 3), but air temperature explained an additional part of lizard body temperature after factoring out the effect of substrate temperature (Multiple Regression, $R^2 = 0.83$; $p < 0.001$; N = 22). The mean activity temperature and the range of body temperatures attained by *M. agilis* were similar to those of other Brazilian species of this genus (e.g., *M. macrorhyncha*: 31.9 ± 3.2 SD, Rocha 1994; *M. bistriata*: 32.9 ± 1.0 SD, Vitt and Blackburn 1991).

Diet.—We found 19 types of prey in the stomachs of *Mabuya agilis* (Table 1). The diet was composed mainly of arthropods, with 30.2% of total prey volume consisting of termites (Table 1). Termites were also the most important prey items in terms of number (69.8%) and frequency (61.1%), although coleopterans were also important prey (13.4% by volume, 7.5% by number, and 44.4% by frequency) (Table 1).

TABLE 1. Volume (in mm^3), number, and frequency of each prey taxon in the diet of *Mabuya agilis* at Linhares, southeastern Brazil (N = 18 lizards examined).

Item	Volume (%)	Number (%)	Frequency (%)
Isoptera	714.8 (30.2)	139 (69.8)	11 (61.1)
Coleoptera	318.9 (13.4)	15 (7.5)	8 (44.4)
Araneae	69.6 (2.9)	8 (4.0)	7 (38.9)
Psocoptera	2.3 (0.0)	7 (3.5)	2 (11.1)
Homoptera	65.1 (2.7)	6 (3.0)	6 (33.3)
Larvae			
Lepidoptera	311.0 (13.1)	5 (2.5)	4 (22.2)
Coleoptera	70.0 (2.9)	2 (1.0)	2 (11.1)
Orthoptera	111.5 (4.7)	3 (1.5)	3 (16.7)
Diptera	2.2 (0.0)	3 (1.5)	2 (11.1)
Hymenoptera	15.9 (0.7)	2 (1.0)	2 (11.1)
Thysanura	29.1 (1.2)	2 (1.0)	2 (11.1)
Blattodea	15.6 (0.6)	1 (0.5)	1 (5.6)
Hemiptera	5.7 (0.2)	1 (0.5)	1 (5.6)
Embioptera	3.3 (0.1)	1 (0.5)	1 (5.6)
Collembola	0.5 (0.0)	1 (0.5)	1 (5.6)
Pseudoscorpionida	0.3 (0.0)	1 (0.5)	1 (5.6)
Pupae	15.8 (0.7)	1 (0.5)	1 (5.6)
Lacertilia	478.8 (20.1)	1 (0.5)	1 (5.6)
UAR *	143.7 (6.0)		
Total	2377.7	199	

* UAR = unidentified arthropod remains.

The diversity of prey types found in the stomach of *Mabuya agilis* is characteristic of sit-and-wait predators (Huey and Pianka 1981; Schoener 1971). Conversely, the predominance of a prey type with relatively low mobility and a clumped distribution in the environment, such as termites, is typical of the diet of wide-foraging predators (Huey and Pianka 1981; Magnusson et al. 1985). The combination of sit-and-wait and wide-forager strategies seems to be common among skinks of the genus *Mabuya*, of which a number of species have been suggested to adopt both foraging strategies (Vanzolini et al. 1980; Vitt 1991; Vrcibradic and Rocha, ms. submitted). Considering sit-and-wait and wide foragers as two extremes of a continuum of foraging patterns, the data on feeding habits of *Mabuya agilis* indicate that this lizard has a feeding behavior that lies at an intermediate point between the two extremes. Anderson (1993) has recently referred to skinks as "proximal intensive foragers" compared to the wide-intensive foraging mode of the teiid *Cnemidophorus tigris*.

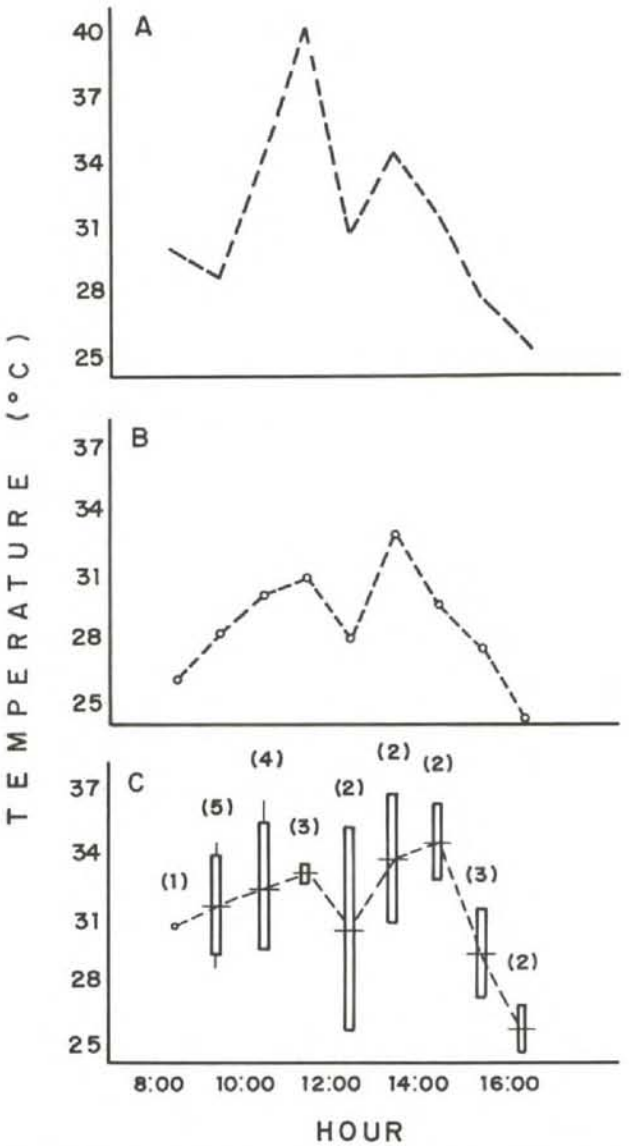

FIG. 2. Mean substrate temperature (top), mean air temperature (middle), and body temperature of *Mabuya agilis* (bottom) in the Nativo of Linhares. In the bottom graph horizontal lines, vertical bars, and vertical lines represent respectively the mean, standard deviation, and range. Temperatures in °C.

One adult individual of *Mabuya agilis* (SVL = 57.8 mm) had a juvenile lizard (*Tropidurus torquatus*) in its stomach. The ingestion of small vertebrates (e.g., lizards and frogs) is apparently not uncommon among *Mabuya*, as observed in other studies (e.g., Vitt and Blackburn 1991; Vrcibradic and Rocha, ms. submitted). *Tropidurus torquatus* is the most abundant lizard in the study area (Bergallo and Rocha 1994) and this observation indicates that *Mabuya agilis* is a potential source of mortality for juvenile *T. torquatus*.

Acknowledgments.—We thank A. A. Giaretta, S. M. Gandolfi, and I. G. Varassin for their help in collecting the lizards. Helena G. Bergallo and M. Van Sluys kindly read the manuscript and offered helpful suggestions. The Companhia Vale do Rio Doce provided logistic support and permission to access the reserve. The Department of Zoology of the Universidade Estadual de Campinas, through the GPE, provided financial support. The Conselho Nacional para o Desenvolvimento Cientifico e Tecnológico (CNPQ) provided a research grant (Process No. 300 819/94-3) to CFDR.

Observations on the Escape Behavior of the Horned Lizard *Phrynosoma mcallii*

The horned lizards of the genus *Phrynosoma* are morphologically specialized, primarily myrmecophagous iguanids whose behavior and ecology tend to set them apart from other genera of lizards (Pianka and Parker 1975; Stebbins 1985). Horned lizards respond to potential predators with one or more defense mechanisms: cryptic coloration, mimicry of natural habitat features, immobility, running a short distance and then burial under loose substrate, cephalic horns, blood squirting, hissing, body inflation, jumping, rocking, and open-mouthed attack (Middendorf and Sherbrooke 1992; Milne and Milne 1950; Norris 1949; Sherbrooke 1981, 1991; Sherbrooke and Montanucci 1986; Smith 1946; Stebbins 1985; Tanner and Krogh 1973).

Norris (1949) and Stebbins (1985) reported that when approached or frightened, *Phrynosoma mcallii* dove into the sand after a short run to escape potential predators. This type of escape behavior is very similar to that exhibited by fringe-toed lizards (*Uma* spp.). Thus, *P. mcallii* was thought to occur only in aeolian habitat within its range, as in the case with the fringe-toed lizard, *Uma notata* (Norris 1949; Stebbins 1985). We observed *P. mcallii*, however, in areas without substantial aeolian sand. These areas are primarily hardpan covered with a layer of gravel and sparse vegetation. Because of their cryptic coloration, motionless *P. mcallii* are hard to detect on this type of substrate (personal observations). So the question arises, is remaining motionless the only mechanism *P. mcallii* uses to protect itself from potential predators in areas devoid of sand? In this paper we report the escape and defense behavior of *P. mcallii*.

The areas for this study were (1) Ocotillo Wells State Vehicular Recreation Area, (2) the southern portion of the Superstition Mountains, and (3) southern East Mesa, all in southeastern California; all were areas considered favorable for *P. mcallii* by Turner and Medica (1982). The lizards were encountered during contract surveys or incidental sightings on foot, or in a vehicle in April, and June through August 1994. Capture methods and handling of *P. mcallii* were approved by the California Department of Fish and Game and the San Jose State University Institutional Animal Care and Use Committee, Protocol No. 633.

Sixty-four (89%) of the 72 *P. mcallii* encountered crouched low and remained motionless. Of the lizards approached on foot (N = 65), 63 lizards (97%) flattened themselves against the substrate and/or were motionless, while of those encountered in a vehicle (N = 7), only one (14%) remained in place. Thirty-one of the lizards that crouched low were observed on sandy substrate, while 33 were on hardpan/gravely substrate. When lizards were about to be grasped, they remained motionless (73%) or ran (27%).

Handled *P. mcallii* would often wiggle their head, causing their sharp occipital horns to dig into the handler's hand, often causing their release. This type of defense behavior was noted in Smith (1946) and might be effective against predators that handle struggling prey in their mouth (Sherbrooke 1990).

Some *P. mcallii* ran for a short distance (< 20 m) when about to be grasped. Of the lizards that fled (N = 17), a total of 9 escaped capture by running into a burrow, 4 ran to the base of a shrub, and 4 crouched down a short distance further in front of, or behind us. Seven of the lizards that ran into a burrow were encountered on hardpan/gravely substrate, while 2 were on sandy substrate. Hardpan/gravely substrate was present in all cases for those lizards that ran to the base of a shrub. For those that crouched down a short distance away, only one was observed on sandy substrate, the rest on hardpan/gravely substrate. Norris (1949) reported that *P. mcallii* would either dive into the sand or crouch down after a short run. Of the *P. mcallii* encountered on sandy substrate none was observed to dive into the sand after a short run, and only one buried itself at the base of a dead shrub.

Most of the *P. mcallii* seen from a vehicle ran for a short distance and stopped. Four ran across off-highway motor vehicle riding trails and stopped at a base of a shrub, while 2 stopped on the riding trail. The impact of off-highway motor vehicles on *P. mcallii* populations is presently unknown.

Most of the lizards we encountered, regardless of substrate type, remained motionless which we assumed maximized the effectiveness of their cryptic coloration to escape potential predators (Norris 1949; Sherbrooke and Montanucci 1986; Stebbins 1985). Of the lizards that fled, some used rodent burrows for escape after the short run. This aspect of their behavioral ecology merits further study as they have a wider habitat preference than previously believed (Stebbins 1985).

Acknowledgments.—We thank Wade Sherbrooke and Howard Shellhammer for valuable suggestions on the manuscript. We thank Anza-Borrego Desert State Park Superintendent Dave Van Cleve and the staff for providing living accommodations during the study. Thanks are also given to Ocotillo Wells SVRA Superintendent Curt Itogawa for the use of the park facilities and equipment. The horned lizard surveys were supported by a grant from the Off-Highway Motor Vehicle Division of the California Department of Parks and Recreation, Contract No. C9314012.

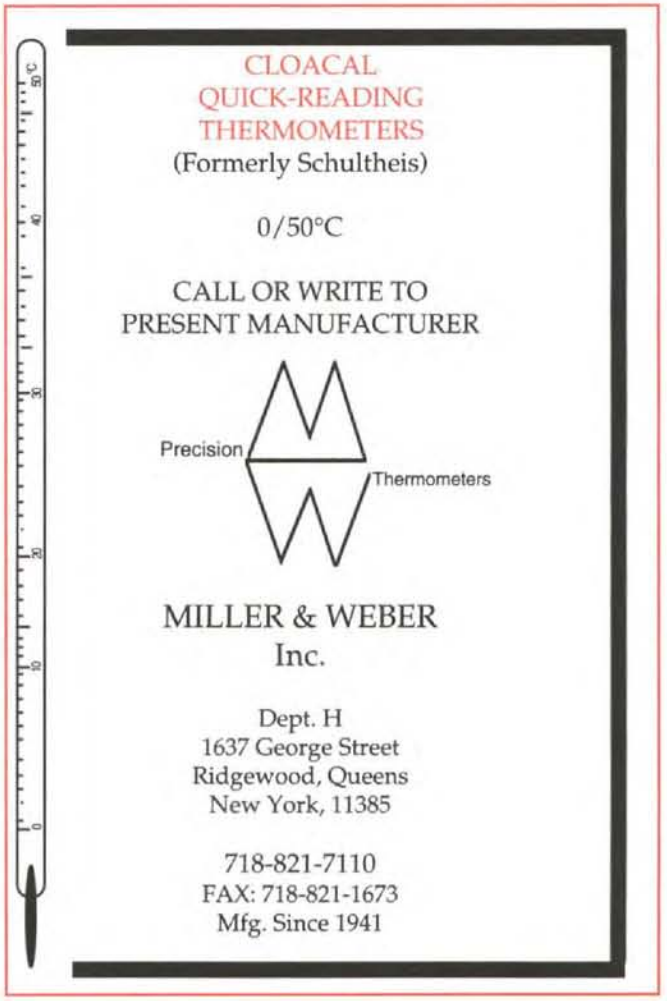
Trachemys scripta elegans in Southwestern Spain

In recent years, the introduction of foreign species has become a common practice in Spain, including Extremadura (southwestern Spain). The crustacean *Procambarus clarckii* (pers. observ.), the fish *Micropterus salmoides* and *Lepomis gibbosus* (Lope and Cruz 1985), and the bird *Amandava amandava* (Cruz et al. 1981) can now be found in this region, and permanent breeding populations are established. As regards the herpetofauna, *Rana catesbeiana* was reported north of Cáceres, the frogs having escaped from a commercial culture operation (García París 1991). In this note we report the presence, in Badajoz province, of a chelonian of American origin, *Trachemys scripta*, from two areas 80 km apart. Courtship behavior is also reported.

In the summer of 1993, a specimen of *T. scripta* was captured in the Río Zapatón (22 km north of Badajoz city). Two other individuals were subsequently reported by a fisherman in the same place. In March 1994, we observed two specimens on three occasions at the dam of Cornalvo (70 km east of Badajoz city).

The captured specimen was an adult female with a carapace length of 201.6 mm, a plastron length of 199.5 mm, and a weight of 1426 g. This specimen is referrable to the subspecies *T. s. elegans* (using the descriptions by Behler and King 1979).



The estimated carapace length of the two individuals observed at the dam of Cornalvo was 170–180 mm. Most of the time they were inactive and basking. At dusk on 9 March, they began a series of movements. Because terrestrial telescopes were used, our observations were restricted to the movements which took place on the water surface. One of the individuals remained motionless, with its head and carapace above the surface, while the other appeared and disappeared at several points around it. The second individual occasionally emerged facing the static one, which would follow it for a short distance as it swam backwards. These behaviors have been reported for females and males respectively (Jackson and Davis 1972). Occasionally, the more active individual threw small water spouts toward the other, a behavior reported in the neotropical races *T. s. grayi* and *T. s. ornata* (Lovich et al. 1990).

The introduction of this species has been confirmed in different countries (Bouskila 1986; Daniels 1994; Ernst 1990; Newbery 1984; Platt and Fontenot 1992), as well as in North American areas outside its natural range. Also, *T. scripta* has been reported in some Spanish locations where the development of stable populations seems unlikely (García-Paris and Martín 1987; García-Paris et al. 1989; Rivera and Arrivas 1993). This is the first report of this species in Extremadura. The ecological features of our two sites are very different. Adjacent riparian vegetation (*Fraxinus* sp., *Salix* sp., *Populus* sp., *Rubus* sp., *Arundo* sp., *Phragmites* sp., *Typha* sp., and *Juncus* sp.), and areas of submerged vegetation provide good protection on the banks of the Río Zapatón, close to the optimum habitat for the species (Morreale and Gibbons 1986). In contrast, the dam of Cornalvo is completely bare, with rocky soil, although the surrounding area has holm oak and low brush, *Cistus* sp. and *Quercus* sp. being the dominant vegetation (Mediterranean forest). *Trachemys scripta* coexists with *Mauremys leprosa* in both places, and perhaps also with *Emys orbicularis* in Cornalvo, since the latter occurs in adjacent brooks.

The turtles from Cornalvo are within the size range for mature individuals (Jackson 1988), and the described behavior suggests that they are breeding, with the consequent risk of settlement. The size of the captured female and the descriptions of the other individuals suggest that the same could be happening in the Río Zapatón.

The potential for competition between *T. scripta* and the native species (*M. leprosa* and *E. orbicularis*) needs to be studied (Bouskila 1986). If the range of *T. scripta* expands, a displacement of the native species can be expected, as is suspected for *Pelomedusa subrufa* in South Africa (Newbery 1984), and *Mauremys caspica* in Israel (Bouskila 1986). This event would have especially deleterious consequences for *E. orbicularis*, as it is far more endangered and scarce in Extremadura than is *M. leprosa* (da Silva 1993). Steps are being taken to eliminate *T. scripta* individuals, and decisions will have to be made on the trade of exotic species and their subsequent establishment, as four to seven million hatchlings are sold annually in the international market (Warwick 1991). Due to its broad ecological tolerances, omnivorous diet, and dispersal ability, it seems likely that breeding populations of *T. scripta* will become established in southwestern Spain, an area of habitats and climate similar to parts of its native range (Morrelae and Gibbons 1986). This supports the need for controls on the international market for this species.

Acknowledgments.—The authors would like to thank colleagues at the Area de Biología Animal, particularly Casimiro Corbacho and Emilio Costillo, for their collaboration in the recording of *T. scripta* nuclei. José Gambeta provided the captured individual. The authors would especially like to thank Ricardo Morán for his collaboration in the observations and for the translation of this note, and Ignacio Izaguirre and Jesús Pascual for the revision of this translation. Finally the Agencia de Medio Ambiente of Extremadura provided the licenses for the capture and observation of the specimens that made this study possible.

Fox Snake Winter Activity in Central Illinois

The western fox snake (*Elaphe vulpina vulpina*) is distributed in the north-central midwest (Powell 1990). In the northern portion of its range (e.g., Wisconsin), the snake inhabits forested areas and various other habitats (Vogt 1981). An isolated eastern race (*E. vulpina gloydi*) in the region bordering Lake Huron and Lake Erie occurs in extensive marshes (Conant and Collins 1991). In marked contrast, *E. v. vulpina* persists in agricultural areas that were formerly prairie in the Prairie Peninsula of central Illinois and Indiana (L. E. Brown and J. R. Brown 1975; Minton 1972; Smith 1961). Even though *E. vulpina* is commonly encountered, Ernst and Barbour (1989) pointed out that it is the least known of the species of *Elaphe* in North America. Furthermore, little information is available on the thermal ecology of the species (Ernst and Barbour 1989). The most notable contributions were provided by Dill (1972) who recorded body core temperatures from transmitters implanted in a single individual during August–September in Minnesota, and Costanzo (1986) and Zaremba (1978) who collected temperature data within and near hibernacula (cisterns) in Wisconsin in late summer, fall, and spring. We report the observation of substantial winter surface activity by an *E. v. vulpina* in central Illinois. This is highly unusual behavior because snakes, as ectotherms, are known for their lack of surface activity during the cold months of winter in northern regions.

Our observations occurred at an ice skating party on 17 February 1991 on Peterson's Pond (a human-made impoundment), 4.7 km NNE Hudson, Illinois (NW 1/4, NE 1/4, SE 1/4, Section 3, T25N, R2E, Hudson Township, McLean County), USA. The *E. v. vulpina* was first noticed at 1440 h on the south edge of the pond. It proceeded to move slowly over the ice across the center of the pond. The guests at the ice skating party were located some distance away and did not chase or pursue the snake. When the *E. v. vulpina* reached the opposite side of the pond it was collected. It had traveled 39.6 m across the ice. When captured, the *E. v. vulpina* was quite cold and lethargic, but after it was taken inside, it eventually warmed up and behaved normally. No *E. v. vulpina* are kept as pets in this rural area, and thus it is probable that the *E. v. vulpina* we observed was not an escapee from captivity. The specimen was an adult male with a total length of 101 cm and tail length of 17 cm (measured alive).

Air temperature near Peterson's Pond was observed to be 9.4°C shortly after the capture of the *E. v. vulpina*, but the thermometer was not shaded and not of scientific quality. Maximum and minimum temperatures on 17 February 1991 were +6.7 and -3.3°C respectively, recorded at the Illinois State University weather station in Normal, Illinois, some 16 km to the south of Peterson's Pond. For the five days preceding 17 February 1991, the mean minimum temperature was -12.6°C (range was -3.3 to -17.8°C). Mean maximum temperature for the same five days was -1.2°C (range was +3.9 to -11.7°C). Maximum temperature was above 0°C on only two of the five days. On 12 and 14 February 1991, trace amounts of snow were recorded at the Illinois State University weather station. However, on 15 February 1991, 1.8 cm of snow fell with 40.2–48.3 km/hour winds resulting in poor visibility and blizzard-like conditions. By the afternoon of 17 February 1991 most of the snow on the ground near Peterson's Pond had melted but some patches remained from the snowfalls of 15 February 1991 and earlier dates. The ground was still frozen except for about 1 cm which had thawed on the surface. The pond ice had been measured on 11 February 1991 and was 45.7 cm thick.

In Wisconsin, Vogt (1981) indicated that *E. v. vulpina* leave their denning areas in the last two weeks of April, but in western/northwestern Indiana, Minton (1972) did not find the species earlier than 5 May. Smith (1961) stated that *E. v. vulpina* "can be found from early spring until late fall" in Illinois. His reference to "early spring" may reflect his finding of 16 *E. v. vulpina* in an old well in March (no specific date given). Wells are often used as hibernacula by snakes (e.g., W. S. Brown et al. 1974). In the area around Peterson's Pond, *E. v. vulpina* is commonly encountered (see L. E. Brown and J. R. Brown 1975), but in the 23 years prior to 17 February 1991 and in the three subsequent years we never saw any specimens in winter or spring before May. However, other snake species in the area (e.g., *Storeria dekayi*, *Thamnophis sirtalis*) have sometimes been observed in April.

Rising temperatures are usually considered a major stimulus for emergence of reptiles from hibernation but this has received little experimental investigation (Gregory 1982). The somewhat higher air temperature may have been responsible for the winter surface activity of the *E. v. vulpina* we observed. However, the air temperature was not unusually high, and was typical for February in central Illinois. Vibrations produced by participants in the ice skating party may also have been a factor responsible for the snake's emergence, particularly the frequent movement of a garden tractor pulling sleds and skaters around the pond and on the ice. A number of times the tractor moved over the earthen embankment of the pond near the location where the snake was first seen, although the tractor stopped some time before the appearance of the *E. v. vulpina*. We suspect that the *E. v. vulpina* emerged from a hibernaculum in the embankment or on the south-facing slope of an adjacent ravine.

Costanzo (1988) and Costanzo et al. (1988) demonstrated in the laboratory that *Thamnophis sirtalis* can survive entombment in ice and freezing of 36% of their body water. Furthermore, some species of snakes can supercool their bodies to as low as -3.5 to -7.4°C under experimental conditions (Lowe et al. 1971). However, numerous snake species are known to hibernate at body temperatures well above freezing with no indication of supercooling (W. S. Brown et al. 1974; Jacob and Painter 1980). Gregory (1982) indicated that surface activity on warm days in winter is known for some reptiles in warmer parts of their ranges, e.g., *Crotalus viridis* in New Mexico (Jacob and Painter 1980). In contrast, mid-winter surface activity is probably rare or nonexistent for most snake species in northerly climates. For example, W. S. Brown (1982) found no evidence for winter emergence from hibernation by timber rattlesnakes *Crotalus horridus* that were closely monitored in New York. Probably the most notable example of winter surface occurrence in a northern region is that of *Vipera berus* in northern Europe but this has only rarely been observed (Viitanen 1967).

In summary, an *E. v. vulpina* was observed in mid-winter (17 February 1991) to slowly move 39.6 m across the ice of a pond in a former prairie region in central Illinois. The cause of the emergence was probably somewhat higher air temperature and/or disturbance to the hibernaculum due to vibrations produced by humans. Winter surface activity is rare in snakes in northern climates.

Acknowledgments.—We thank W. S. Brown and G. Paukstis for bibliographic help; J. S. Keogh for laboratory assistance; M. O'Grady for providing weather data from the Illinois State University weather station; S. and L. Peterson for inviting us to their ice skating party; and J. Brown, W. S. Brown, G. Paukstis, and J. Tucker for critically reading the manuscript.

TECHNIQUES

Techniques for Capturing Arboreal Lizards

One of the more difficult and time consuming tasks in conducting field research is the collecting of animals. Because of increased structural diversity in tropical forests, and the elusiveness of some species, field biologists are continually seeking ways to simplify the collection of specimens. On a recent trip to Amazonian Ecuador we developed and tested a relatively easy trapping method applicable to lizards and to many other types of animals as well.

Tropidurus (= *Uracentron*) *flaviceps* is an arboreal tropidurid lizard of moderate size that lives on large branches in the rainforest canopy. Upon disturbance these lizards immediately retreat into treeholes. Duellman (1978) collected these animals by searching felled trees. This method, however, does not yield large numbers of animals, nor does it lend itself to the study of the ecology and behavior of these animals. Duellman, for example, collected only 2 individuals during four years of field work; Dixon and Soini (1975) collected more, but most were from a single tree. During the course of our field season within the Reserva Faunistica Cuyabeno, we discovered that *T. flaviceps* occurs not only in the canopy of "terra firma" forest, but also in trees of lagoons and seasonally inundated forest. One species of tree in particular, *Macrolobium acaciaefolium* (Leguminosae [Fabaceae]), offers ideal habitat for these lizards. Often at heights in excess of 20 m, the medium and large trees of this species almost always contain one (and usually more) hole into which lizards will retreat. These lizards, however, occur at low frequency. We searched over 600 trees, but only eight (1.3%) contained individual lizards. The high water level in the lagoon during the wet season facilitated access to these trees. After several unsuccessful days of attempting to noose lizards, we attempted three trapping techniques (Table 1).

The first method was to attach mouse glue traps to tree branches (Bauer and Sadlier 1992; Rodda et al. 1993). We chased animals into a hole and nailed Victor® mouse glue traps (cut to a convenient 20 cm x 4 cm) to the tree so that they completely encircled the branch both above and below the hole. We collected four reemerging animals in this manner and subsequently removed lizards from the traps using vegetable oil; the animals did not appear to suffer ill effects from either glue board or oil. Drawbacks to this technique are that the intended trap victim may escape by jumping over the glue board (Zani, pers. obs.) and glue boards lose their ability to hold animals in approximately two days, or after the first hard rain, and must be replaced.

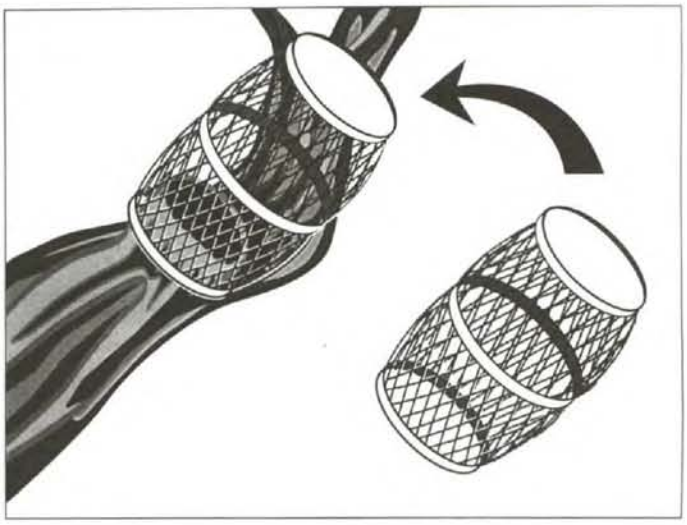

FIG. 1. A method for catching lizards in tree holes by covering the hole with a wire-mesh minnow trap.

Our second technique was "male-baiting." Male *T. flaviceps* are territorial and aggressively defend territories that generally encompass one or more trees (Vitt and Zani, unpubl.). We placed an adult male inside a wire-mesh minnow trap tied to a branch within the territory of another male. Within several hours, the resident male investigated the "intruder" and entered the minnow trap. However, even after two days of baiting we could not trap a second resident male. While this technique was successful once, we deemed it undesirable because it may require a relatively long time commitment (Table 1), and it may work only on territory-holding males.

The third, and most successful, technique was to cover known retreats of lizards with minnow traps. First, we chased lizards into a hole. Then we fitted a wire-mesh minnow-trap, with the entrance modified to accommodate head dimensions of the largest possible male, over the hole (Fig. 1). We used nylon string to tie the trap securely onto the branch, and filled remaining gaps between trap and tree with cloth or covered them with duct tape. We plugged other holes connected to the "trapped" hole with cloth as well. We then left the tree for up to four hours while we investigated or trapped other trees. Within this time period, lizards usually emerged from retreats by the only means available, the trapped hole, and entered the trap. We removed animals by opening one end of the trap as it remained attached to the tree, or by removing the entire trap, placing it into a large cloth sack, and opening the trap (we preferred this method when dealing with multiple, or very active, lizards).

TABLE 1. Number, and time to capture, of *Tropidurus flaviceps* collected using three capture methods.

Method	Total animals trapped	Animals not trapped	Time to capture		Total trap hours
			Minimum	Maximum	
Glue trap	4	3	4 h	1 d	150
Male baiting	1	1	3 h	N/A*	50
Minnow trap	23	1	0.5 h	1 d	250

*After 2 d the male remained untrapped.

It does not seem to matter if another lizard is already in the trap when an animal emerges from its retreat. On several occasions we captured more than one lizard (and as many as 5) during a single trapping event. By using two traps in a single tree we collected 12 lizards in a single day; over the course of a week we collected 23 lizards in the minnow traps. The limit to our collection efforts was the number of traps available and the number of trees we could search in the time allowed. In most cases, we collected all animals that we observed in a tree (and many we did not observe) within a 24 hour period.

Hole trapping appears to be the best method to collect *T. flaviceps*. Not only does it offer the best success ratio (Table 1), but minnow traps are simple and easy to use. Animals living in treeholes are ideal candidates for this collection method; in addition to lizards, we captured a large treefrog (*Osteocephalus taurinus*) and several spiders using the minnow traps. This technique could also be useful for animals dwelling in rock crevices or in terrestrial burrows. The only requirements are that access from the retreat be limited to a single, trapable exit, and that the animal be active enough so that it will re-emerge in a relatively short amount of time.

Acknowledgments.—We thank C. de Vries for providing the canoe for use on the Laguna Grande and C. McCallister for drawing Fig. 1. This research was supported by a National Science Foundation (DEB-9200779) grant to LJV and J. P. Caldwell.

Two Efficient Techniques for Catching Skinks

Noosing, pitfalling, and using rubber bands as projectiles are popular techniques for catching live lizards (Simmons 1987). Similarly, Myers (1956) and Strong et al. (1993) caught frugivorous teiids and small insectivorous lizards by attracting them to fruit or mealworms, respectively, threaded onto fishing line. During a Lyme disease survey, we discovered that lizards of the genus *Eumeces* can be heavily parasitized by immature *Ixodes scapularis* ticks, and we attempted to catch *Eumeces fasciatus, E. inexpectatus,* and *E. laticeps* using pitfall traps and noosing techniques. Pitfall captures were few, and noosed skinks frequently wriggled free before they could be secured. Partly by serendipity we developed two techniques to greatly improve our skink capture rate.

The first technique involves attracting a skink to a cricket, mealworm, or beetle tied or threaded onto fishing line and dangled from a fishing rod. The skink is attracted (even if it has started to retreat) to the insect which is then seized by the skink. The skink can either be lifted off the substrate still grasping the bait (most *E. laticeps* do not relinquish their jawhold) and lowered into a collecting bucket, or may be lured into a net which is carefully moved into place after the skink has developed an interest in the cricket (this technique works better with *E. fasciatus* and *E. inexpectatus*). Skinks that have retreated into a crevice or thick vegetation can often be coaxed out by dangling a cricket close to the refugium. Capture success rate using this technique was 92% (N = 147 attempted captures).

The second technique involves setting Sherman® small mammal traps baited with crickets. In order to increase trapping efficiency, we set traps in areas of known skink activity. Two crickets are secured to each Sherman trap by tightly tying cotton thread around the abdomen or thorax and then attaching the free end of the thread to the trap. One cricket is restrained near the trap entrance while the other is secured inside, at the back of the trap. This technique was successful in all trapping attempts.

These two simple techniques greatly improved our capture rate. We also caught green anoles (*Anolis carolinensis*) and six-lined racerunners (*Cnemidophorus sexlineatus*) using cricket lures, but these lizards did not always accept the bait and were often more easy to catch by noosing.

Acknowledgments.—Techniques were developed under a Faculty Research Grant from Georgia Southern University, a grant from the Edward John Noble Foundation, NIH grants AI24899 and AI30026, and CDC grant U50/CCU406614.

Oxytocin Induced Nesting Behavior in Female Red-eared Turtles, *Trachemys scripta elegans*, without Oviductal Eggs

Oviposition in many species of turtles may be artificially induced by administration of hormones (Ewert and Legler 1978). Ewert (1989) noted that administration of oxytocin induced nesting behavior in oviductal egg-bearing females of *Chelydra serpentina, Clemmys insculpta, Sternotherus carinatus, Kinosternon leucostomum*, and *K. scorpioides* when these species were provided with suitable nesting substrates. During investigations on reproduction in *T. scripta*, we found that administration of oxytocin could also induce nesting behavior in female *T. scripta* without oviductal eggs.

Turtles used in this study were caught while crossing roads en route to nesting areas or at actual nesting areas between 26 May and 19 June 1994. Localities represented were Grafton (N = 6) and Stump Lake (N = 62), Jersey County, Illinois; Swan Lake (N = 95) and Pohlman Slough (N = 15), Calhoun County, Illinois; and Ellis Bay (N = 5) and West Alton Bay (N = 1), St. Charles County, Missouri. Illinois localities are either on or border the lower Illinois River, whereas Missouri localities are either on or border the Mississippi River.

Each turtle was palpated to determine whether it contained oviductal eggs; 51 turtles did not. All oviductal egg-bearing females (N = 133) were administered Sanofi brand oxytocin (20 USP units/ml) to stimulate oviposition at the dosage (1.5 ml/kg = 3 USP units/100 g) recommended by Ewert and Legler (1978). Because some females retain some or all oviductal eggs after oxytocin is administered (Congdon and Gibbons 1985), we palpated each turtle after oviposition appeared to be completed.

We marked all turtles on one or more marginal scutes, and returned them to their original collecting areas at 12 (N = 22), 24 (N = 74), 36 (N = 28), and 48 (N = 9) hours post-injection. Collecting date, release date, and number of oviductal eggs we estimated each turtle retained was recorded.

Even though all turtles had previously oviposited in the laboratory, we observed nesting behavior in six released into the field at 12 h, and in one released into the field at 24 h, post-injection. None of the turtles from the 36 or 48 h groups was recollected after release. The number of turtles found renesting from the 12 h group was significantly greater ($g = 18.43$, $p < 0.0004$, df = 3) than the number found renesting from turtles held for 24 or more hours.

All seven turtles that attempted to re-nest were found the morning after release. Two were moving to the nesting areas, four were in various stages of nest construction, and one turtle had completed an empty nest. None of the recollected turtles contained oviductal eggs.

Despite the fact that oviductal eggs were absent, nesting behavior occurred among some turtles. We attribute this behavior to the continued effects of the injected oxytocin. Although there was no formal control, we did release the 51 non-egg bearing turtles that we believe had nested naturally just prior to capture. Except that they received no injection of oxytocin, we handled these turtles the same as the females that contained oviductal eggs. We did not find any of these turtles making false nesting attempts.

These results suggest important implications for the use of oxytocin in turtle reproductive studies. Any time an aquatic turtle undertakes terrestrial movement it is at increased risk of death (Gibbons et al. 1990). Some turtles, even those with empty oviducts, will undertake nesting migration up to 24 h after artificial induction of oviposition. Consequently, we suggest that turtles be held at least 24 h post-induction to reduce nesting efforts that expose turtles to unnecessary risk of mortality. Our results also indicate that injection of non-egg bearing females with oxytocin might be a useful technique in experimental studies of nesting behavior and nest-site selection.

Acknowledgments.—We thank J. B. Camerer, J. B. Hatcher, and M. M. Tucker for field and laboratory assistance. This work was partially supported by the Illinois Natural History Survey and the Upper Mississippi River System Long Term Resource Monitoring Program.

A Safe Method for Handling Large Snakes in the Field

Restraining large and potentially dangerous reptiles for field studies without using anesthesia can pose risk to researcher as well as subject. Several techniques developed for safely handling crocodilians and venomous snakes are reviewed by Flower (1978), Almandarz (1986), and Gregory et al. (1989). Passive restraint of large boids has not been addressed, possibly because few field investigations into their natural history have been undertaken.

In January 1992, the authors began a long term study of ecology, behavior, and conservation of anacondas, *Eunectes murinus*, in the Venezuelan llanos; more than 200 anacondas ranging between 0.72 m (0.17 Kg) and 5.3 m TL (82.5 Kg) were handled during routine collection of data. In order to reduce stress on the specimen, and to minimize the number of handlers and the time required to take data from each animal, we developed the following method for safely working with anacondas.

While holding the anaconda's jaws closed, a cotton sock of appropriate size is pulled over the snake's head. Once the snake's snout contacted the bottom (toe) of the sock, several wrappings of plastic electrician's tape are firmly, but not tightly, secured over the sock around the snake's neck (directly behind the quadrate bone). The tape will secure the sock on the anaconda's head. Taking care to keep the mouth closed, a second length of tape is secured, over the sock and around the snake's snout (midway between eyes and nostrils) to secure the jaws. At this point the anaconda can be released for measuring, scale counting, scale clipping, parasite collection, blood sampling, etc., without risk to the investigator.

Although anacondas treated in this manner frequently struck with great accuracy, they were unable to inflict injury and usually settled down after a short period. Releasing the snakes into cloth bags or steel barrels for transport may be accomplished by removing the tape and the sock while the animal is restrained. For large snakes, the loose sock was often left in place while the animal was released into the barrel to permit handlers to move away while the snake's vision was still compromised.

This technique proved quite reliable. None of the snakes was able to remove the sock, nor did any bite through it. No health problems were attributed to the use of this technique. This passive restraint method could be used effectively on many species of large, non-venomous snakes in both field and captive situations.

A Backpack Method for Mounting Radio Transmitters to Small Lizards

Capture-recapture methods, used in field studies to determine home range size, activity patterns, growth rates, etc., depend upon relocating individual animals. When this is not easily accomplished, radio telemetry will frequently be used. Telemeters can be mounted externally or implanted surgically in large animals, but smaller animals can pose difficult problems. We developed a backpack and harness for radio transmitters that enabled us to relocate individuals during field studies of the cryptic, and surprisingly mobile, flat-tailed horned lizard (*Phrynosoma mcallii*). Our technique differs from that reported for *P. cornutum*; Munger (1984) used a loop antenna to secure the radio to the lizard.

An SM1 transmitter (AVM Instrument Co.) was constructed to conform to the lizard's curvature immediately posterior to the pectoral girdle and posterior projection of the horns. It was then embedded in dental acrylic with a 4 cm whip antenna extending posteriorly from the middle of the transmitter. The backpack harness securing the transmitter to the lizard was constructed of polypropylene pleating tape and clear polyurethane elastic, materials that are readily available in fabric stores.

Pleating tape is 5 cm wide polypropylene mesh partitioned into three sections by parallel strips of tightly woven polypropylene (Fig. 1A). When an inverted "T" is cut from the pleating tape (Fig. 1A), a 2-cm length of one of the strips of woven polypropylene forms the vertical leg of the "T," and a 2-cm long by 1-cm wide portion of the mesh material forms the horizontal bar of the

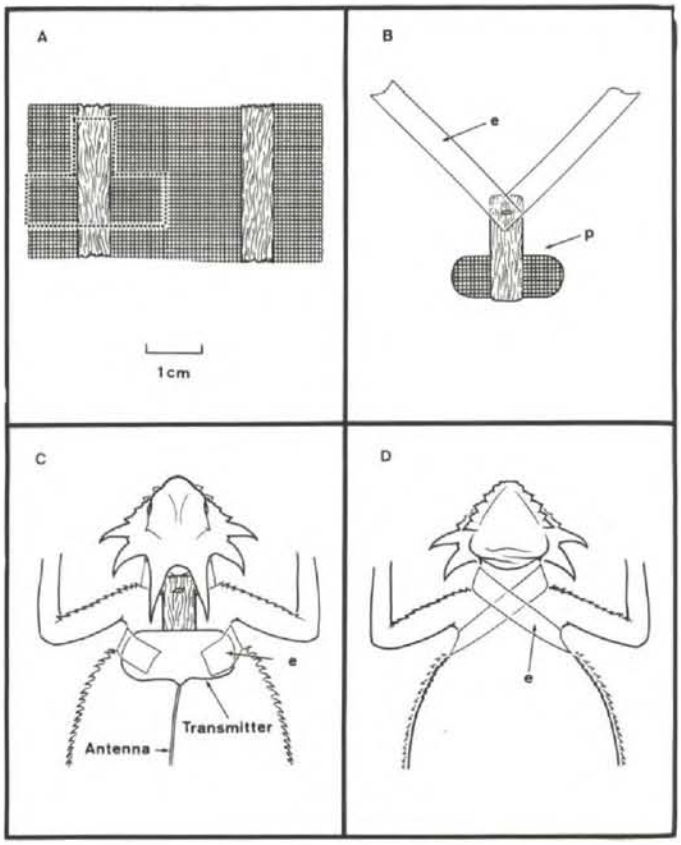

FIG. 1. Preparation and attachment of a backpack harness using pleating tape (p) and polyurethane elastic (e) to secure a transmitter to a horned lizard. See text for details.

"T" (Fig. 1B). After cutting, melt both ends of the woven strip and the perimeter of the mesh material with a soldering iron to prevent unraveling and to conform the mesh material to the shape of the transmitter. Harness straps are then made from strips of clear polyurethane elastic (Stretchrite™) measuring 10 cm by 0.5 cm; polyurethane elastic is thin and lightweight, and maintains elasticity at low humidity and high temperature. Fasten the straps, positioned at about 45°, to the vertical leg of the "T" with cyanoacrylic glue (Superglue™) and a stitch of thread (Fig. 1B). The backpack harness may now be affixed to the transmitter package with dental acrylic.

Position the backpack on the lizard's neck with the antenna pointing posteriorly (Figs. 1C and 1D). Pull a strap over the shoulder of one leg and through the axilla of the other leg, and fasten it to the top of the transmitter package with a drop of superglue. Fasten the second strap in the same manner, and glue the two straps together where they cross on the venter; this will keep the package from shifting (Fig. 1D). The straps must be pulled sufficiently tight so as to remain snug when the lizard deflates its body and adpresses its ribs following release. This attachment method allows the package to sit firmly on the back of the lizard and restricts movement of neither the head nor the legs.

Total mass of the telemetry backpack (< 4 g) is about 25% of the mass of the adult *P. mcallii* (mean = 15.8 g, range 11.0–25.0 g) that we fitted with transmitters; the backpack was comparable in mass to an egg clutch for this species, about 27% of total body mass (Pianka and Parker 1975). Newly captured adults were fitted with transmitters and held in captivity for 5 to 10 d to allow them to become accustomed to the backpack in the absence of predators. In captivity the lizards resumed feeding immediately after attachment of the transmitters; in the field, released lizards also resumed normal activities (eating, mating, constructing burrows, etc.). Individuals were recaptured every 2–4 months to exchange batteries and to take body measurements without the transmitter.

Forty-five individual *P. mcallii* were outfitted in this manner from April 1990 through July 1992, for a total of 7944 lizard-days and 1172 resightings. Most individuals carried their backpacks until killed by predators or until we removed the backpack at the end of the study. All lizards in the study were permanently marked with colored beads (Fisher and Muth 1989), enabling us to differentiate "escaped" from newly-captured individuals. Few individuals slipped out of their harnesses, but the backpack was shed when the straps failed in three cases. In two of these cases, the glue joint failed; a strap broke on one backpack harness. Evidence from two other losses indicates predator assistance (puncture holes and tears in straps and acrylic).

This method of attachment can be used on other species of horned lizards as well as on species with less specialized body forms.

Acknowledgments.—We thank Victor Horchar and Tracey Weiss for assistance in the field. Barbara Kermeen (AVM) took things in stride and provided technical advice when we arrived at her office with lizards in hand. The California Department of Fish and Game provided funding (FG9268) and the University of California's Boyd Deep Canyon Desert Research Center provided logistic support.

HERPETOLOGICAL HUSBANDRY

A Simple Method of Mite Control

Lizards play host to a broad range of ectoparasites. In a group of San Esteban chuckwallas *(Sauromalus varius)* located at the Arizona Sonora Desert Museum, mites of the species *Hirstiella pyriformis* and *H. trombidiformes* were found to be prevalent ectoparasites. The chuckwallas were housed indoors in 76 x 76 x 40 cm wooden cages with screen fronts and windows on the sides. An incandescent heat light and 20-watt fluorescent fixtures equipped with both blacklight and Chroma 50 (GE) tubes were attached to the ceilings of the cages. Mites and their egg sacs were commonly found in the corners of the cages, adjacent to and under light fixtures, along the crevices created by the closed cage doors, and external to the cages along the stand/cage juncture as well as on the lizards. These mites migrate to lay their eggs and then to search for a host.

Historically mites have been battled on two fronts: eradication of mites on the lizard and in the cage. Topical application of such chemicals as Dri-Die (Farkas 1993; Loomis 1985), Wermectin (Farkas 1993), and alcohol require handling and restraint of the animal as well as careful application to avoid such delicate tissues as eyes and mucous membranes. Ivermectin, which may be topically applied or injected (Abrahams 1992; Nathan 1994), raises the additional risks of needle damage and improper dosages. All of these chemicals may be injurious or cause death to the animal if used improperly (Farkas 1993; Loomis 1985; Nathan 1994).

Mite control in cages is often attempted by the application of dilute bleach solutions (Nathan 1994), trichlorfon (Boyer and Boyer 1991), or Wermectin (Farkas 1993) sprays. These methods require removal of the animal and careful husbandry lest the animal, its food, or water come into contact with any of the residual chemicals. Vapona (Loomis 1985) and No-pest (Farkas 1993; Nathan 1994) strips have been placed in cages with the animals; the strips must be encapsuled to prevent animal contact and the water bowl must be removed (Farkas 1993; Loomis 1985; Nathan 1994).

With such stipulations regarding the current methods of mite control, new methods which neither require veterinary prescriptions, husbandry changes or large budgets, nor present acute toxic reactions or latent poisoning situations, need to be considered. I have developed a technique for physical removal of mites and their eggs which avoids these problems.

One-inch wide strips of masking tape were applied to the internal and external walls of the cages, usually at a horizontal orientation. Tape locations included adjacent to cage windows, doors, and along the upper cage walls and ceiling junctions out of reach of the lizards. Only the center of the tape was fixed to the cage.

TECHNIQUES

A Simple Aquatic Funnel Trap and its Application to Wetland Amphibian Monitoring

Techniques for monitoring adult amphibians at breeding sites are described by Scott and Woodward (1994) and Dodd and Scott (1994). Quantitative sampling techniques for larvae are reviewed by Shaffer et al. (1994). In these reviews, aquatic funnel trapping was bypassed as a method for monitoring adults but recommended as a tool for estimating species richness and relative abundance of larvae.

In unpublished studies, I used large, bulky, and expensive wire mesh funnel traps (e.g., minnow traps) to determine palustrine wetland use by adult *Pseudacris regilla*, *Taricha granulosa* and *Ambystoma gracile*, and stream use by larval *Dicamptodon tenebrosus*. I baited traps with plain or shrimp oil dipped salmon eggs (Pautski's Balls of Fire) in a perforated 35 mm film canister to increase the capture rate of amphibians. Calef (1973) used a trap made by fastening an insect screen funnel into a 3.5 liter (1 gallon) plastic jug to capture tadpoles of *Rana aurora*. Calef, however, provided no other details such as jug diameter or specific mode of application. Whitman (1974, cited in Riley and Bookhout 1990) used a plastic aquatic funnel trap to capture macroinvertebrates. Riley and Bookhout (1990) altered Whitman's trap to monitor invertebrate activity in the water column. The adapted trap is constructed by stapling top and bottom ends from two 2-L plastic beverage bottles together.

The absence of explicit design characteristics for amphibian funnel traps in the herpetological literature (Dodd and Scott 1994; Scott and Woodward 1994; Shaffer et al. 1994), my successful amphibian census experiences with minnow traps, and the publication of Riley and Bookhout's (1990) inexpensive and easily constructed invertebrate funnel trap prompted me to investigate the potential merits of Riley and Bookhout's trap in amphibian censusing. I describe here the details of trap materials and construction, with modifications that have enabled me to use it successfully for wetland amphibian censusing under diverse habitat conditions without adult and larval mortality.

Materials and Construction.—Each funnel trap set-up requires two clean, clear plastic, 2-L soda-pop bottles, three 0.32 cm (1/8 inch) diameter aluminum rivets with a 0.48 - 0.63 cm (3/16-1/4 inch) grip range, three 0.32 cm (1/8) inch) diameter aluminum washer plates, three plastic clothespins, and one 0.79 cm (5/16 inch) or slightly thicker stainless steel rod of length determined by water depths to be sampled.

Using a razor blade I cut an initial slit near the top of one bottle approximately 0.3 cm below the end of the neck taper within the bottle's midsection. I separate the top by continuing the cut with scissors around the bottle. I similarly cut the bottom from the second bottle with a cut 0.3 cm beyond the seam at the base but again within the midsection of the bottle. The top ends of both bottles are saved. Next I use a hot nail to burn four 0.32 cm holes into the larger section and into the clothespins. I burn one air/water exchange hole 0.3 cm below the bottle's taper within the midsection, and three rivet holes in a straight line at 4, 9, and 14 cm from the bottom along the opposite side. I also clip roughly 1/4 of the plastic from one handle of each clothespin and then burn a 0.32 cm hole into the center tip section of each unclipped end. I then rivet a clothespin through the handle to each hole in the bottles' midsection. Finally, I reverse the short tapered funnel end and slide it within the bottom of the main bottle forming a tight, escape-proof fit and overlapping lip for stapling (Fig. 1).

Applications.—I have attached up to three traps along one stainless steel rod to simultaneously measure captures in 2 m of water at several depths within the water column. In deep water I position traps vertically with funnel side down. This maintains the required air pocket within the top so captured amphibians don't suffocate. In shallow water I drive rods with attached traps diagonally in the water, again making certain to provide air pockets. Water-filled traps not fastened to rods sink and will kill captured amphibians. Although heavier than aluminum, I use stainless steel rods because they do not corrode and therefore, minimize water quality impacts. I also bait traps with 5-10 salmon eggs but have never tested trapping success between baited and unbaited traps, nor between shrimp and non shrimp oil dipped eggs.

I found my funnel trap set-up invaluable in determining spring arrival times of breeding *Ambystoma macrodactylum*, *Ambystoma gracile*, *Taricha granulosa*, *Rana aurora* and *Pseudacris regilla*. Leonard and Richter (1994) have successfully combined several months of aquatic funnel trapping with mark-recapture statistics to census adult *Ambystoma macrodactylum* populations in a small breeding pond. At some wetlands these aquatic funnel traps captured adult amphibians that were not previously detected by visual searches, dipnetting, or pitfall trapping.

Funnel traps also enabled me to describe the spatial and temporal microhabitat use by larval *Ambystoma gracile* and *Rana aurora* (Richter, in prep.). I have captured larvae using these traps with minimal habitat disturbance, by simultaneously trapping in yellow water-lily (*Nuphar polysepalum*), cattail (*Typha latifolia*), and soft rush (*Juncus effusus*) dominated emergent plant communities and in open water areas of varied depths, over 8-hour day, 8-hour night, and during 48-hour trapping periods without mortality. Karlstrom (pers. comm.) used these traps successfully in 1994 to

capture *Rana cascadae*, *Rana aurora*, and *Bufo boreas* tadpoles in his amphibian recolonization studies of Mt. St. Helens. He also captured *Rana catesbeiana* tadpoles, *Ambystoma gracile* neotenes, and *Rana aurora* sub-adults in other wetland studies.

To date capture data suggest that these baited funnel traps are excellent in attracting and capturing adult salamanders but may only incidentally capture adult frogs and toads. Moreover, these traps appear to capture larval salamanders, toads and frogs equally well. Although results are promising, additional testing is required to accurately interpret funnel capture data and provide supplementary ecological information about amphibians. Calef (1973), for example, calibrated capture success of traps against known numbers of *Rana aurora* tadpoles in enclosures to estimate populations of an entire lake. Eggers et al. (1982) determined the area of a trap's capture field by developing mathematical equations relating trap spacing to capture rate per trap. They then estimated abundance of fish by extrapolating catch data from the presumptive area fished by each trap to the entire survey area. Statistically rigorous studies should be performed to determine success in capturing amphibians of different taxa, sex, and size, and whether intra and inter-specific agonistic behavior and the presence of predators influence capture data. Likewise, the probability of capture varies between habitats, and must be determined prior to using funnel trap data for population estimation.

In summary, I find aquatic funnel trapping an under utilized but effective method for characterizing wetland breeding amphibian populations. Further, it offers significant potential for examining differential use of wetlands by adult and larval amphibians.

Acknowledgments.—I thank Bill Leonard for his ideas and suggestions for improving this manuscript and Heather Roughgarden for her field assistance and funnel trapping activities. I am also grateful to Fred Weinmann, USEPA Region 10, Rich Sumner, USEPA ERL-Corvallis, and Bill Sanville, USEPA ERL-Duluth, for providing research funds to carry out these studies.

The Use of RAPD Markers for Species Identification in Desmognathine Salamanders

Many salamander species are so morphologically similar that unequivocal assignment of species by physical analysis alone is virtually impossible for some specimens. When such similar species are sympatric, identification can be problematic, making species determination possible only by protein or DNA analysis in some cases (Larson and Chippindale 1993). This problem is frequently encountered with members of the genus *Desmognathus*. Four to five syntopic species of desmognathine salamanders can be found in some habitats, and identification of all individuals is not always possible on the basis of morphology. Identification can be particularly difficult with larvae and juveniles.

The purpose of this study was to determine whether randomly amplified polymorphic DNA (RAPD) markers could be found that were intraspecifically consistent and interspecifically distinct for desmognathine species, and therefore useful for species identification. RAPD markers have been used for the identification of morphologically indistinguishable strains and varieties of a wide range of organisms, including mice (Welsh et al. 1991), fungi (Goodwin and Annis 1991), bacteria (Akopaynz et al. 1992) and apples (Koller et al. 1993). The method is relatively inexpensive, and has proven both reliable and reproducible.

The use of RAPD markers generated by the polymerase chain reaction (PCR) offers certain unique advantages for this type of analysis. Unlike most DNA analysis techniques, RAPD does not require cloning, DNA sequence information, or the use of radioactive isotopes, and results can be obtained within a few hours of tissue collection. Because only minute quantities of DNA are necessary for RAPD analysis, it is possible to sample even small salamanders in a non-destructive fashion. In addition, as demonstrated here, RAPD markers do not exhibit developmental variation, and samples can be taken from embryos, larvae, or from any tissue source, such as tail or toe clippings. The ability to use such minute quantities of virtually any tissue source gives RAPD an advantage over allozyme analysis. Further, while allozyme analysis is limited by the number of available enzymes, the vast number of different primers available makes it possible to generate practically unlimited markers for the comparison of specimens with RAPD.

Materials and Methods.—Twenty-five *Desmognathus ochrophaeus* (five adults from each location and five embryos from a single location) were collected from two locations in Macon, Co. North Carolina (35°10'N, 83°13'W and 35°05'N, 83°35'W) and two locations in Garrett Co., Maryland (39°36'N, 79°07'W and 39°30'N, 79°28'W). Six adult *Desmognathus monticola* were collected from each of two locations, one in Macon Co., North Carolina (35°10'N, 83°13'W), and one in Garrett Co., Maryland (39°36'N, 79°07'W). Five adult *Desmognathus fuscus* were collected from each of two locations 30 km apart in Garrett Co., Maryland (39°36'N, 79°07'W and 39°30'N, 79°28'W). Six *Desmognathus quadramaculatus* were collected from a single site in Macon Co., North Carolina (35°10'N, 83°13'W). Five *Leurognathus marmoratus* were collected from each of two altitudinally distinct populations in Macon (35°00'N, 83°15'W, elevation 700 m) and Haywood 35°18'N, 82°50'W, elevation 1600 m) Counties, North Carolina. All specimens selected for this study could be unequivocally assigned to species by morphological examination. Specimens represented different size classes and (presumably) different age classes.

DNA isolations followed the protocol described by Gustincich et al. (1991). Tissue sources were varied and included liver, embryos, and the tips of tails. DNA amplification was carried out using the method described by Williams et al. (1990) with modifications. The concentration of input DNA was varied to determine the optimal concentration for each primer. The reaction mixes were divided into two components separated by a layer of paraffin wax (Aldrich Chemical Co.) to prevent initiation of the reaction prior to the start of thermal cycling. Taq polymerase was obtained from Promega, Inc. Primers were obtained from Operon Technologies, Inc. Primer sequences were as follows:

OPA-01 CAGGCCCTTC
OPA-02 TGCCGAGCTG
OPA-03 AGTCAGCCAC
OPA-04 AATCGGGCTG
OPA-05 AGGGGTCTTG
OPA-06 GGTCCCTGAC
OPA-07 GAAACGGGTG
OPA-08 GTGACGTAGG
OPA-09 GGGTAACGCC
OPA-10 GTGATCGCAG
OPA-11 CAATCGCCGT
OPA-12 TCGGCGATAG
OPA-13 CAGCACCCAC
OPA-14 TCTGTGCTGG
OPA-15 TTCCGAACCC

Reactions were conducted in an MJ Research, Inc. MiniCycler. Reactions were carried out at least two times for all samples with all primers to determine reproducibility of patterns. Amplification products were electrophoresed through 2% agarose gels.

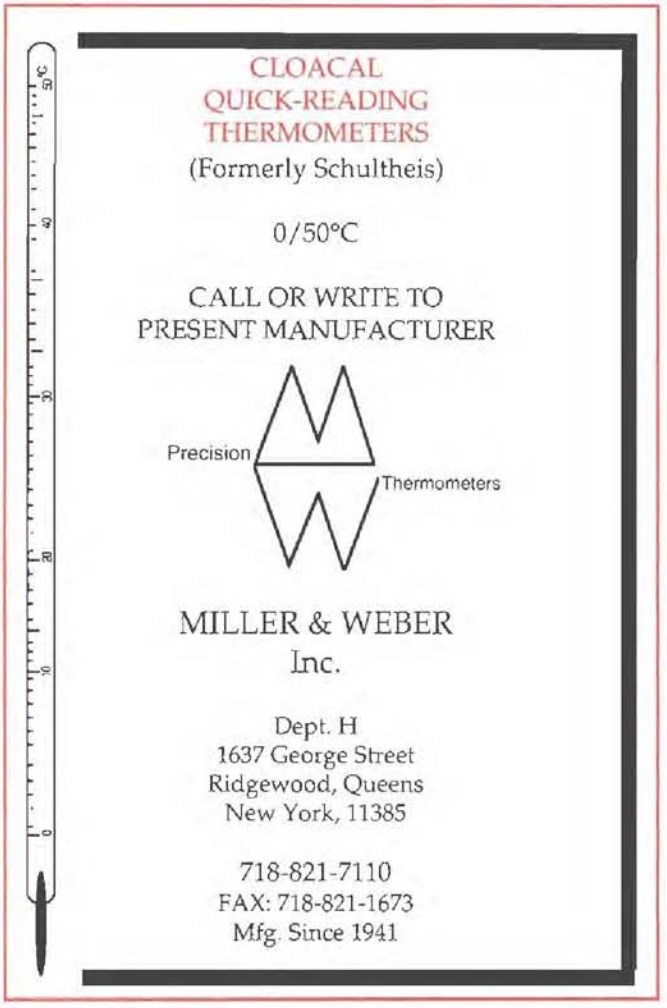
Results and Discussion.—Of the 15 primers used, six (OPA-01, OPA-02, OPA-04, OPA-06, OPA-10, and OPA-15) provided markers that could be useful in distinguishing some or all of the species investigated here. The other nine primers generated markers that were either so highly conserved that multiple species shared similar or identical markers, or so highly variable that markers were not consistent within individual species. Duplicate reactions indicated that markers were reproducible, with only minor variations, in all cases. The results shown are representative of all specimens examined.

For each of the six informative primers, markers typically were generated for every individual from a given collection site that were consistent with, and specific to, the species designation obtained by morphological examination. However, in some cases, consistent markers were not found for members of the same species obtained from different collection sites, or in the case of *D. ochrophaeus*, obtained from the same collection site. An example of this can be seen with the use of OPA-01 (Fig. 1). *Desmognathus fuscus* and *D. monticola* markers were consistent between collection sites, while *D. ochrophaeus* samples yielded markers that differed between collection sites and even within a single site. (For an example of the use of highly variable RAPD markers in the study of *D. ochrophaeus* populations see Masters and Forester, ms. in prep.).

Another example of intraspecifically consistent and interspecifically distinct markers for *D. fuscus* and *D. monticola* collected from two different sites, and for *D. quadramaculatus* and *L. marmoratus* collected from a single site, can be seen with the use of OPA-10 (Fig. 2). Markers generated from *D. ochrophaeus* samples with this primer differed between populations, and between individuals within populations (data not shown).

An example of markers that can be used for species identification of *D. ochrophaeus* specimens can be seen in Figure 3. Of the 15 primers used in this study, one (OPA-15) generated species-specific markers for all 25 *D. ochrophaeus* individuals examined (twenty adults and five embryos). The markers labelled A and B in Fig. 3 were found in all D. *ochrophaeus*, and the marker labelled A was unique to that species. *D. ochrophaeus* DNA samples isolated from tails, livers, and embryos all gave a consistent and characteristic pattern with OPA-15, indicating that varying tissue sources can be used for identification. Consistent and diagnostic markers also were obtained with this primer for *D. fuscus* and *D. monticola*. However, this primer did not generate markers that could reliably distinguish *D. quadramaculatus* and *L. marmoratus*. The markers obtained for each of 12 *L. marmoratus* specimens (six from each of two sites) were site specific, but not species specific. The markers generated from *L. marmoratus* samples collected at one site could be confused with the markers generated for *D. quadramaculatus* because of similar mobilities.

The use of RAPD is shown here to be a reliable method for species identification of salamanders in the genus *Desmognathus*, if proper care is taken. It was possible to generate RAPD markers that were consistent with the morphological identification of all the specimens examined in this study, and samples could be obtained nondestructively (tips of tails) and from different tissues (tail, larvae, and liver). Several caveats must be observed, however, when using this technique for species identification.



While species-specific markers generated with multiple primers were conserved between the two analyzed Maryland populations of *D. fuscus*, and for the Maryland and North Carolina populations of *D. monticola*, analyses of *D. ochrophaeus* and *L. marmoratus* from different populations indicate that markers are not necessarily conserved between populations of a particular species. There is no way to predict whether markers generated with a particular primer, and for a given species, will be conserved between, or even within, populations. Therefore, it is necessary to test primers with unambiguously identified specimens from those localities where morphologically unidentifiable specimens will be collected in order to identify consistent and distinctive markers for each species of interest.

The complexity of salamander genomes varies considerably from species to species, and the procedures described here were only carried out on desmognathine salamanders. Members of the genus *Desmognathus* have relatively less complex (smaller) genomes than do many species of salamanders (Sessions and Larson 1987), and it is possible that some species will present greater difficulties than those examined in this report. However, judicious choice of primers, adjustment of annealing temperatures, or an increase in the primer length, should make the technique applicable to any organism. Indeed, RAPD has been used successfully for the analysis of plant species with extremely complex genomes (Dweikat et al. 1993; Heun and Helentjaris 1993).

While a comprehensive discussion of the technique is beyond the scope of this note (see reviews by Hadrys et al. 1992, and Black 1993), several general concerns should be noted. The patterns obtained by RAPD are extremely sensitive to reaction conditions and care must be observed to ensure reproducibility. The temperature profile is particularly critical. MacPherson et al. (1993) obtained different RAPD patterns with identical samples and reaction conditions when thermal cyclers of different manufacture were used. In addition, the investigators found patterns to be sensitive to primer concentration, as did Muralidharan and Wakeland (1993). However, when moderately high DNA concentrations (greater than 10 ng) and sufficient primer concentrations (at least 0.2 micromolar) were used, MacPherson et al. concluded that all thermal cyclers examined were capable of reproducibility. Care must also be taken with the enzyme used. Schierwater and Ender (1993) have found that use of polymerase obtained from different sources (with regard to both manufacturer and organism) may lead to variation in RAPD markers. Anyone who wishes to produce useful RAPD profiles must standardize their reaction conditions with regard to all of these factors.

The considerable technical difficulties inherent to RAPD should not be underestimated. However, this method offers unique advantages over other available molecular techniques for species identification. For the identification of extremely small specimens, eggs, or larvae, the technique is likely to be particularly useful. Although the technique is described here only for the analysis of desmognathine salamanders, it seems probable that the technique should be applicable to virtually any species. I hope that this report will serve to encourage greater cooperation between field-oriented and lab-oriented biologists, and allow the use of recent technological advances to answer questions generated by observations in the field and, more specifically, to encourage exploration of the use of RAPDs in other salamander species.

Acknowledgments.—Thanks are extended to D. Forester for help with specimen collection and identification, and for many helpful comments on the manuscript. I would also like to thank A. Wilson for technical assistance, R. Bruce for assistance with specimen identification, and L. Mangurian for reviewing the manuscript. This work was supported in part by grants from the Towson State University Office of Sponsored Research and the Highlands Biological Station, Highlands, North Carolina.

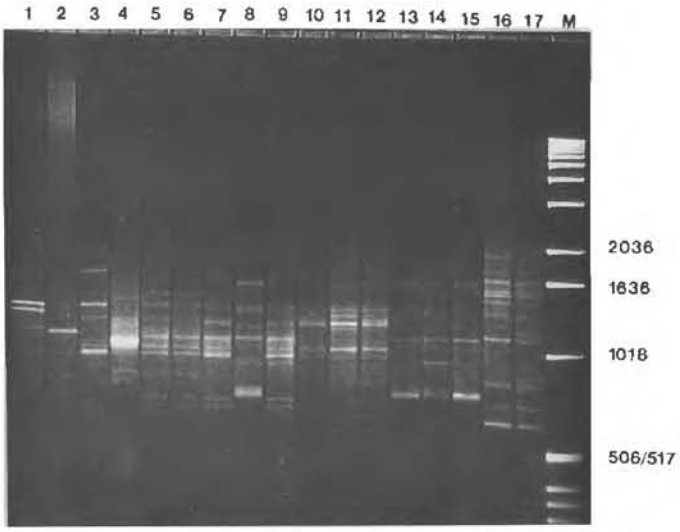


FIG. 1. RAPD products generated using OPA-01. Each lane represents a separate individual. Lanes 1 and 2, *D. ochrophaeus* from a single locality in Macon Co., North Carolina. Lane 3, *D. ochrophaeus* from a second locality in Macon Co., North Carolina. Lane 4, *D. ochrophaeus* from Garrett Co., Maryland. Lanes 5 and 6, *D. monticola* from a single locality in Garrett Co., Maryland. Lanes 7 and 9, *D. monticola* from a single locality in Macon Co., North Carolina. Lane 10, *D. fuscus* from Garrett Co., Maryland. Lanes 11 and 12, *D. fuscus* from a second locality in Garrett Co., Maryland. Lanes 8 and 13-15, *D. quadramaculatus* from a single locality in Macon Co., North Carolina. Lanes 16 and 17, *L. marmoratus* from a single locality in Macon Co., North Carolina. DNA samples were isolated from liver in all cases, except for lanes 1-3, where DNA was isolated from tails. Lane M contains DNA size standards. See text for discussion of RAPD products.

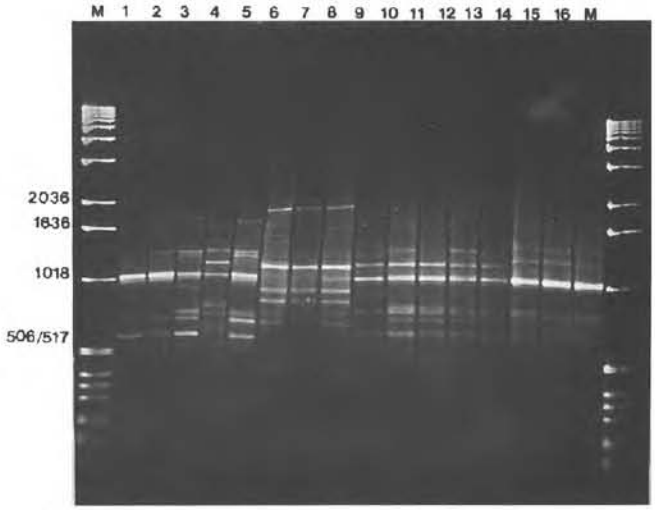

FIG. 2. RAPD products generated using OPA-10. Each lane represents a separate individual. Lanes 1 and 2, *D. monticola* from a single locality in Garrett Co., Maryland. Lanes 3 and 5, *D. monticola* from a single locality in Macon Co., North Carolina. Lane 6, *D. fuscus* from Garrett Co., Maryland. Lanes 7 and 8, *D. fuscus* from a second locality in Garrett Co., North Carolina. Lanes 4 and 9-13, *D. quadramaculatus* from a single locality in Macon Co., North Carolina. Lanes 14-16, *L. marmoratus* from a single locality in Macon Co., North Carolina. All DNA samples were isolated from liver. M lanes contain DNA size standards. See text for discussion of RAPD products.

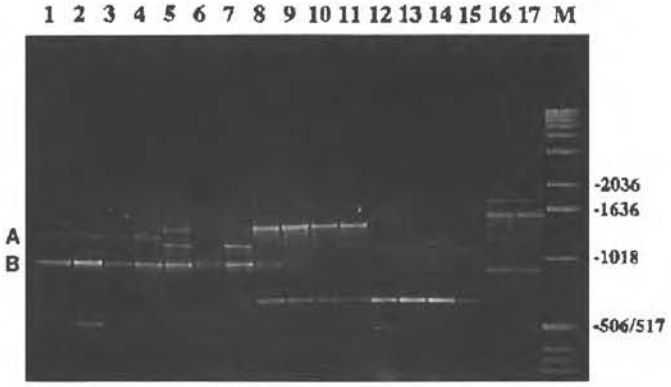

FIG. 3. RAPD markers generated with OPA-15. All lanes represent separate individuals. Lanes 1 and 2, *D. ochrophaeus* from a single locality in Macon Co., North Carolina. Lanes 3 and 4, *D. ochrophaeus* from a single locality in Garrett Co., Maryland. Lane 5, *D. fuscus* from Garrett Co., Maryland. Lanes 6 and 7, *D. fuscus* from a second locality in Garrett Co., Maryland. Lanes 8 and 9, *D. monticola* from a single locality in Garrett Co., Maryland. Lanes 10 and 11, *D. monticola* from a single locality in Macon Co., North Carolina. Lanes 12-14, *D. quadramaculatus* from a single locality in Macon Co., North Carolina. Lane 15, *L. marmoratus* from Macon Co., North Carolina. Lanes 16 and 17, *L. marmoratus* from a single locality in Haywood Co., North Carolina. DNA used in lanes 1 and 2 was isolated from embryos, all other samples were isolated from liver. Markers labelled A and B were found in all 25 *D. ochrophaeus* samples analyzed. See text for discussion of RAPD products.

HERPETOLOGICAL HUSBANDRY

Spawning of *Notophthalmus viridescens* and Rearing of Embryos Under Laboratory Conditions

The adult red spotted newt, *Notophthalmus viridescens*, has long served as the model for the study of appendage regeneration, and other body parts (see reviews by Sicard 1985 and Wallace 1981). A basic paradigm concerning epimorphic regeneration in the adult newt implies that the amputated limb retraces its embryonic development (Faber 1971; Liversage 1991). With the advent of molecular biology, the need for embryonic newt tissue to further test this paradigm is becoming acute. A major obstacle in this endeavor has been the inability of researchers to obtain or to produce and raise newt embryos in sufficient numbers. We outline, for the first time, a systematic means to produce as well as rear large numbers of embryos on a year round basis.

Spawning Chamber.—A glass aquarium (51 cm L x 27 cm W x 31 cm H) containing 25L of dechlorinated tap water (22°C, maintained by constant room temperature), a 5 cm layer of aquarium gravel, several rocks (which protrude out of the water) as well as a mixed variety of aquatic plants (e.g., *Sagittaria* sp. and *Elodea* sp.) housed the adult newts. Each chamber is covered with a fine metal mesh lid (not glass) above which is mounted a 33-watt General Electric "gro and sho bright stik" (model FBS25/GS) fluorescent light plugged into an adjustable timer. Spawning chambers are kept in a windowless room so that both the quantity and quality of light can be regulated closely. Ideally, each chamber should house 4 female and 2 male newts which are sexually mature. These newts can be kept in a spawning chamber indefinitely.

Natural Spawning.—According to Fankhauser (1967), animals caught in the wild during spring will spontaneously deposit eggs if housed in an aquarium containing a mass of aquatic plants. We have found that by cooling males and females 2–3 times a week to 5–10°C overnight, as well as over-feeding them with minced beef heart, *Daphnia* sp., and *Tubifex* sp., and gradually increasing the photocycle 15 min/day for 14 days tends to enhance the yield of embryos. A moderate supply of eggs (20–50 per animal) may be harvested over a period of approximately 3 days to 4 weeks.

Induced Spawning.—Large newts (>12 cm snout to tail tip) of both sexes (2N = 22, ZW = female, ZZ = male, Nace 1974) are selected for breeding. Best results are obtained when noticeably gravid females are chosen. Males with blackened distal hindlimb digital pads as well as blackened inner (medial) surfaces of their hindlimb (nuptial) pads are the most suitable for mating. In addition, prominent distension of the cloacal region resembling a cone, as well as the dorso-ventral broadening of the tail are other indicators of sexual maturity in both genders. Animals chosen for spawning are maintained in clear plastic tubs (35 cm L x 26 cm W x 15 cm H) containing dechlorinated tap water at 22°C. Newts should be well-fed on a varied diet, as described above, for at least two weeks. Water is changed daily. Following overfeeding, animals are placed at 4°C and left in complete darkness for periods varying from overnight to 5 days, whereupon, the animals are returned to room temperature (22°C) and placed in spawning chambers. Initially, animals are exposed to a 10h light:14h dark photocycle. The light portion of the photocycle is increased 15 min per day for 14 days. After the first 7 days of photoacclimation females are injected (primed) in the evening with 100 I.U. of human chorionic gonadotropin (HCG – Sigma, #CG-5; see Redshaw 1972). HCG is injected i.p. into a mildly anaesthetized (by immersion in 0.05% w/v MS 222 neutralized with $NaHCO_3$) female using a 30-gauge needle fitted to a 1.0 cc tuberculin syringe. The following morning, females are given a further 100 I.U. HCG. Should eggs not appear 7 days after the initial HCG treatment, further injections of 100 I.U. HCG may be given on a daily basis. Eggs may be harvested immediately following their deposition on the plant material. These matings typically result in more than 150 viable embryos per female over a period of several weeks to about two months, if the spawners are well fed and left as undisturbed as possible.

Larval and Eft Maintenance.—Egg clusters are recovered daily from the spawning chambers by removing the egg-laden plant sprigs and transferring them directly into aquaria (62 cm L x 31

FIG. 1. Scanning electron micrograph of a newt blastula fractured through the blastocoel revealing internal structure.

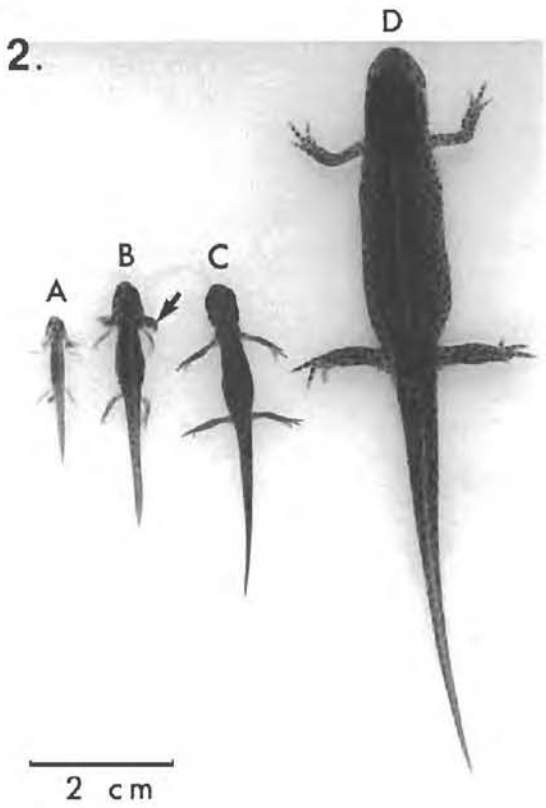

FIG. 2. Light micrograph showing the developmental progression of *Notophthalmus viridescens* from the larval brown eft stage to the mature adult. A. Growing brown eft. B. Mature brown eft with prominent gills (arrow). C. Red eft, lacking external gills as a result of metamorphosis I—transition from water (brown eft) to land (red eft). D. Mature gravid adult (female). Result of metamorphosis II—transition from land (red eft) back to water (adult).

cm W x 42 cm H) containing well established cultures of *Daphnia* sp. Eggs develop in aquaria filled with 22°C dechlorinated tap water and are exposed to a 12h light:12h dark photocycle. The resulting embryos are allowed to develop and are either collected by stage (Fig. 1) as needed, or allowed to mature. Once hatched, the free swimming larvae will begin to consume *Daphnia* sp. Larger brown efts are fed *Tubifex* sp. as well. Efts require live, moving food (Martin et al. 1973). When housed in this manner, handling and maintenance are reduced to a minimum. This limits stress to the animals. Furthermore, animals can eat ad libitum, which assists rapid growth. In addition, fungal contamination of newt larvae appears to be reduced when they are fed on *Daphnia* sp. obtained from cultures which are maintained in water containing algae. *Daphnia* need not be fed yeast. First metamorphosis occurs when brown efts (Fig. 2) prepare, physiologically and morphologically, to move from water to land. Once their external gills have been resorbed, efts become red (Fig. 2) and they are ready for the terrestrial phase. However, we have observed that red efts grow larger and more quickly when left in an aquatic habitat lacking a terrestrial component. Instead of providing land, several large sprigs of *Elodea* sp. should be floating at the surface of the water. Red efts are fed liberally on *Daphnia* sp. and *Tubifex* sp. When raised in this manner, efts thrive well due to a ready access to an abundant food supply; a reserve of which cannot be maintained easily in a terrestrial environment in the laboratory. To date, we have successfully produced in excess of 5000 *Notophthalmus viridescens* embryos in one year using the techniques outlined. We have spawned animals that have been kept in our lab for more than 3 years. Nevertheless, the greatest ease in spawning as well as the highest yields have been obtained from animals that have been brought in "fresh" from the wild between October and May. Our newts are purchased from Michael Tolley, Nashville, Tennessee, USA. In contrast, the most difficult period in obtaining a continuous supply of embryos is from June to September. Although females appear gravid during this period, most of the eggs they deposit are not fertilized. Moreover, we have found that these unfertilized eggs tend to be deposited singly instead of in clusters.

ANURA

LEPTODACTYLUS BUFONIUS (NCN). **REPRODUCTION.** *Leptodactylus bufonius* breeds in unpredictable habitats in arid Chacoan regions of Paraguay, Argentina, and Bolivia. Males construct nests in the mud at the edges of ponds and other low-lying depressions. They call from inside or close to the nests, and subsequent production of a foam nest occurs within the mud nest. Following oviposition, the top opening of the nest is closed off with mud. The eggs hatch within a few days, but the tadpoles remain within the closed mud nest until rains flood the nest and wash the tadpoles into the pond (Cei 1949. Acta Zool. Lilloana 8:105–110). The tadpoles are able to remain inside the nests for at least 46 days (Philibosian et al. 1974 Herpetologica 30:381–386) if rains do not cause the nests to open. The tadpoles are primarily ureotelic while in the foam, thus urea concentration remains below the lethal limit (Shoemaker and McClanahan 1973. Comp. Biochem. Physiol. 44A:1149–1156). Although nest construction has been described in the papers cited above, no description of nest capping (closing of the nest opening with mud), nor mention of which sex performs the behavior, has been reported. This note offers observations of three females engaged in nest-capping behavior.

Field observations were made on 5–6 December 1989, at a farm pond along Ruta 41, about 56 km NE of Joaquin V. Gonzalez, Salta Province, northern Argentina. Duration of the pond was extremely unpredictable, containing water at irregular intervals from early December through early March. The pond at the time of observation in early December was approximately 15 m X 30 m and had a maximum depth of 30 cm. From 1700–1800 h on 5 December I located and marked 12 mud nests from around the edge of the pond. All nests were cone-shaped and extended up to 5.5 cm above the ground (Fig. 1A). Distance from the edge of the water ranged from 0.51–13.8 m (mean = 3.8 m, SD = 3.68). Nest depth ranged from 8.7–13.5 cm (mean = 11.5 cm, SD = 1.35), and width of the nest opening ranged from 4.5–6.5 cm (mean = 5.4 cm, SD = 0.66).

I checked for anuran activity at the 12 nests beginning at 2330 h, 5 December. Males were found calling from inside three of the nests, and from the ground within 1 m of another two nests. Amplectant pairs were found inside four of the nests, in the process of producing foam nests. The remaining three nests had no frogs associated with them. I observed these 12 nests from 2330–0330 h. None of the five calling males attracted a female during the observation period. The following are observations on the four nests in which eggs were deposited.

Nest #1 (2.55 m from the edge of the pond). I first observed the amplectant pair in the mud nest at 2330 h. From this time until 0150 h both frogs were inside the nest, but by 0205 h both frogs had left the nest When I returned at 0220 h, one frog was capping the nest opening. The frog used its front feet to push mud from the ground, along the side, up to the top of the nest, working all around the sides of the nest. It continued this activity until I caught it at 0302 h, although the frog was still pushing mud up onto the top of the nest, the opening had been completely closed by the time I caught the frog. The individual was a female. No other frog was found within 10 m of the nest.

Nest #2 (13.8 m from the edge of the pond). A pair of frogs was observed in this nest at 2335 h. The pair was still inside the nest at 2435 h. At 2450 h one frog was found sitting 4.5 cm from the nest. The nest opening had not been capped. The frog remained in this position for another 2 h 40 min, at which point I caught it and identified it as a female. The nest remained open at the top. The earth surrounding the nest was so dry and hard that perhaps it was not possible for the female to cap the nest opening.

Nest #3 (51 cm from the edge of the pond). A pair of frogs was observed in this nest at 2340 h. They remained in the nest until at least 0140 h. When I returned at 0212 h one frog was pushing mud up along the sides of the nest, and a second frog was sitting 30 cm from the nest. The individual doing the capping was a female, the one sitting near the nest a male. When I returned at 0236 h and again at 0254 h the nest opening was completely closed, but the female was still pushing mud onto the top and the male was still sitting in the same position 30 cm from the nest. At 0254 h I disturbed the frogs and they both jumped into the water. When I returned at 0311 h the female was once again pushing mud onto the top of the nest, but the male was not found.

Nest #4 (90 cm from the edge of the pond). A pair of frogs was observed inside the mud nest at 2345 h. They were still inside the nest at 2445 h. When I checked the nest at 0145 h a frog was pushing wet mud up along the side of the nest, onto the top. No other individual was observed within 10 m of the nest. I checked

FIG. 1. Mud nest of *Leptodactylus bufonius*. A. Open nest, without foam and eggs inside. B. Capped-off nest. Note that the mud on the top and on the upper sides of the nest is wetter than the mud on the bottom of the nest and on the surrounding substrate.

this nest at 10–15 minute intervals, and each time found the individual still capping the nest, although the opening appeared to be closed by 0225 h. At 0240 h I caught the individual and identified it as a female.

Based on these observations, it seems that the female is the parent who remains and caps the nest, although males may remain nearby after oviposition. In all three instances where I observed the process of nest capping, the mud placed onto the nest top was considerably wetter than the mud on the ground (see Fig. 1B). Thus it seems likely that the female uses water from her bladder to moisten the mud in order to make it more sticky and easier to form into a protective cap.

Because capping behavior represents a considerable time investment (in the three instances observed the times were minimally 42–59 min) and presumably subjects the female to a greater risk of predation, the behavior is an important component of reproductive effort in the species. *Leptodactylus bufonius* would be a fascinating species for which to compare reproductive effort between the sexes: males expend considerable time and energy constructing the mud nest and calling to attract a mate, and females expend energy closing the nest, presumably for protection from desiccation and predators.

I thank Omar Pagaburo for field assistance and Raymond F. Laurant and the Miguel Lillo in Tucuman for logistical support. Carlos Videla and Ignacia Sarmiento kindly granted permission to work on their land. Rodolfo Ruibal read the manuscript and provided helpful comments.

RANA CAPITO SEVOSA (Dusky Gopher Frog). **SUBMERGED VOCALIZATION.** Several ranids, including *Rana palustris* (Christiansen and Bailey 1991. The Salamanders and Frogs of Iowa. Iowa Dept. Nat. Res. Nongame Tech. Ser. No. 3. 24 pp.), *R. areolata* (Barbour 1971. Amphibians and Reptiles of Kentucky. Univ. Press of Kentucky, Lexington. 334 pp.), *R. pipiens* and *R. sylvatica* (Pope 1944. Amphibians and Reptiles of the Chicago Area. Chicago Nat. Hist. Mus. Press, Chicago. 275 pp.) have been reported producing both airborne and submerged mating calls. We observed submerged dusky gopher frogs calling at breeding sites in Florida and Alabama.

On 29 January 1994, we heard muffled calls of gopher frogs at Holley Pond on Eglin Air Force Base (AFB), Okaloosa County, Florida (T1N, R25W, Sec. 28). The calls were audible at ca. 10 m. Two males were subsequently observed calling while sitting on the pond bottom on 31 January 1994. On 13 February 1994, several males were observed calling from the bottom of Salt Pond in Conecuh National Forest, Covington County, Alabama (T2N, R15E, Sec. 3). Submerged vocalization was also heard at an unnamed pond on Eglin AFB (T1N, R25W, Sec. 28) on 1 March 1994. We have heard dusky gopher frogs producing airborne calls at the Eglin ponds in previous years, and muted, presumably submerged calls at Salt Pond in 1991 and 1992.

Submerged vocalization is not confined to western Florida and southern Alabama. Gopher frogs have been heard calling under water in North Carolina (A. Braswell, pers. comm.), Georgia (J. Jensen, pers. obs.), and Mississippi (G. Johnson, pers. comm.). Calling from above or below the surface does not appear to be affected by air temperature, as we have heard both at air temperatures between 7.5 and 17°C. Males calling under water may be establishing territories, and/or attempting to attract females already in the pond. Submerged vocalization may also conserve energy and reduce exposure to predators that prey on more conspicuous surface-calling frogs.

Submerged calling has important implications for aural surveys of gopher frogs. Because submerged calls are only audible at 10 m or less, gopher frog presence or absence cannot be accurately determined when frogs are calling under water without listening at various points within or around the wetland basin. This is particularly pertinent when other species of frogs, such as *Pseudacris ornata*, are chorusing. In addition, because submerged calls are more difficult to discern than airborne calls, the numbers of calling males may be underestimated. Submerged calling may at least partially explain why Bailey (1990, *In* C. K. Dodd, Jr., et al., eds. Proc. Eighth Ann. Mtg. Gopher Tortoise Council. Florida Mus. Nat. Hist, Gainesville. 134 pp.) heard fewer males calling than had entered a breeding site encircled with a drift fence.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA, **JOHN G. PALIS**, RR 1, Box 258, Tell City, Indiana 47586, USA, and **MARK A. BAILEY**, Alabama Natural Heritage Program, Dept. of Conservation and Natural Resources, State Lands Division, 64 N. Union Street, Montgomery, Alabama 36130, USA.

RANA CATESBEIANA (Bullfrog). **DIET**. On 1 July 1992, four adult bullfrogs were collected by one of us (JB) from ponds on a reclaimed coal mining site in Randolph County, Missouri (T54N R15E Sec 22). Frogs were captured at night with the aid of a headlamp. The following animals were found in the bullfrogs' stomachs: two frogs had crayfish (*Orconectes virilis*, or *Cambarus diogenes*, ca. 120 mm), one frog had what was believed to be a prairie vole (*Microtus ochrogaster*, 120–130 mm) and the fourth bullfrog had eaten a young female mink (*Mustela vison*, ca. 180 mm). This adds to the published information on the diet of bullfrogs in Missouri (Johnson 1987, The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **JEFF BERINGER**, Missouri Department of Conservation, 1110 South College Ave., Columbia, Missouri 65201, USA, and **TOM R. JOHNSON**, Missouri Department of Conservation, P.O. Box 180, Jefferson City, Missouri 65102, USA.

SCAPHIOPUS INTERMONTANUS (Great Basin Spadefoot). **PRODUCTION OF ODOR**. Several groups of frogs, including some pelobatids, are known to produce specific odors that are similar to everyday smells, such as garlic, onions, or vanilla (Noble 1931. The Biology of the Amphibia. McGraw-Hill Co., New York. 577 pp.). The western spadefoot (*Scaphiopus hammondii*) is reported to smell like roasted peanuts when handled (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.), but this apparently has not been noted for *S. intermontanus*.

On the evening of 13 July 1994 we collected four *S. intermontanus*, each about 5.5 cm SVL, along a road between Oliver and Osoyoos, British Columbia (49°03'N, 119°28'W). While measuring and weighing the first, we noticed a peculiar odor which reminded us of peanuts. The next three spadefoots also produced this odor, as did another caught on 31 July 1994. This time the odor seemed to coincide with the extrusion of a cream-colored opaque substance from the parotoid glands. We found three small spadefoots on 16 August 1994, and three more on 7 September 1994 (each about 3 cm SVL); all could be induced to produce the peanut smell. The mucous-like secretion dried to a crust on the hands and produced a burning sensation

when accidentally rubbed in the collector's eye. Upon capture, some of the specimens dipped their heads, tilting their backs towards the collector's hand. Two of the spadefoots also regurgitated when held for an extended amount of time; one produced several larval lepidopterans and a beetle while the other only produced bubbles. We suggest that this group of behaviors enables spadefoots to discourage or distract predators. The specimens were handled for a few minutes before they produced the scent and secretion, so if spadefoots are caught and immediately placed in a container they might not feel sufficiently threatened to react in the manner described.

TESTUDINES

EMYDOIDEA BLANDINGII (Blanding's Turtle). **REPRODUCTION.** A radio-tagged female Blanding's turtle was observed nesting on 21 June 1993 in Crow-Hassan Park, Hassan Township, Hennepin Co. Minnesota (45°15'N). The turtle nested in a re-created prairie with sparse grass cover. The soil is sandy and well drained. Prior to being planted with prairie plant species in the mid 1970s, the site was used for row crops. The nest was monitored throughout the summer. When the nest was checked on 11 October 1993, it was undisturbed. When visited on 25 October, there was an exit hole. Upon excavating the nest, five hatched eggs were found along with three unhatched eggs. Thus five of the eggs took a minimum of 112 d from the time they were laid to the time the hatchlings emerged from the nest. The unhatched eggs were reburied. When the nest was dug up in March 1994, the three eggs had hatched and no hatchlings were present. As there was no exit hole, we presume the hatchlings emerged the previous fall sometime after 25 October 1993. The time from laying of these three eggs to emergence of hatchlings from the nest was therefore at least 126 d. Both emergence times are longer than the 104-day maximum reported in Ernst et al. (1994. Turtles of the United States and Canada. Smithonsian Inst. Press, Washington. 578 pp.). Temperatures were 1.7°C below normal and precipitation was 17.5 cm above normal during the incubation period at this site.

STERNOTHERUS MINOR (Loggerhead Musk Turtle). **FORAGING DEPTH.** On 20 October 1992 an adult male *S. minor* was encountered feeding on a crayfish (Astacoidea) underwater at a depth of 12.5 m. The observation was made in Catfish Hotel, a spring-fed sink hole at Manatee Springs State Park, Levy County, Florida. The sex of the turtle was determined based on its relative head size. After being observed for several seconds, the turtle abandoned the partially eaten crayfish and retreated under a log at 13 m depth. Dive depths of freshwater turtles have not been well documented. Most freshwater turtles are presumed to forage in shallow habitats where depth does not pose physical or physiological limits. This report suggests that *S. minor* forages at substantial depths when deep habitats are available.

Manuscript preparation was supported by contract DE-AC09-76SR00-819 between the U.S. Department of Energy and the University of Georgia.

LACERTILIA

ANISOLEPS GRILLI (NCN). **REPRODUCTION.** On 29 December 1992 we collected a gravid female *Anisoleps grilli* (SVL = 81.86 mm) at the Parque Municipal da Grota Funda (23°15'S; 46°45' W, 900–1400 m alt., 1600 mm rain/year), Municipality of Atibaia, São Paulo, Brazil. The specimen was brought to the lab and, on 8 January 1993, she laid seven white calcareous shelled eggs in a nest excavated between stones at the bottom of the terrarium. The clutch was incubated at ambient temperature (range 17–26° C) and photoperiod in wet vermiculite. Five eggs were adhered to each other. The two free eggs measured 15.5 x 8.9 and 15.5 x 9.1 mm. At the end of the incubation period they were coriaceous in aspect and had grown 57% in length and 62% in width. The mean incubation time lasted 233.8 days (SD = 6.242; N = 5); two eggs died. The mean SVL and weight of hatchlings was 29.4 mm (SD = 0.89; N = 5), and 0.575g (SD = 0.015; N = 4). One of the hatchlings had a malformation of the right eye and head symmetry. The climate at the collection site is seasonal with a hot/moist summer and a cold/dry winter, with frequent frosts in June/July. The hatching was coincident with the beginning of the hot/moist season. Voucher specimens are housed in the collection at Universidade Estadual de Campinas (ZUEC 1542, 1614–18).

AAG thanks the Fundação "O Boticario" and FAEP for financial support for studies in the area, CNPq (AAG) and CAPES (KGF) for providing our grants. We thank A. S. Abe and L. A. Fitzgerald for their helpful comments on the manuscript, and A. L. B. Montagno for her help with the English translation.

CARLIA (Scincidae). **TAIL WAVING AND PREY PIRACY.** *Carlia fusca* (Brown Four Fingered Lizard) was observed to wave its tail while moving through leaf litter (O'Shea 1993. Herpetol. Rev. 24:3). Tail waving has been recorded in the pygopodid genera *Aprasia* and *Ophidiocephalus*, and a number of geckos in Australia (Greer 1989. The Biology and Evolution of Australian Lizards. Surrey Beatty and Sons Pty Limited, Chipping Norton, N.S.W., 264 pp.). Most of these animals have only been observed to wave the tail when disturbed. A number of authors reported tail waving to be widespread within *Carlia* (Horner 1991. Skinks of the Northern Territory. NT Museum; Wilson and Knowles 1988. Australia's Reptiles: A Photographic Reference to the Terrestrial Reptiles of Australia. Collins Publ., Sydney, 447 pp.), and *C. munda, C. rufilatus*, and *C. gracilis* have been observed to display in this manner in the Darwin, NT, region. Most species of *Carlia* are sexually dichromatic, as in many Australian agamid species, and therefore may be visually cued (S. Wilson, pers. comm.). However, tail waving has been observed in animals which are alone, in the vicinity of conspecifics, stationary, and foraging. The behavior does not appear to be sex or season specific. Therefore, if tail waving is a visual cue in *Carlia*, it is perhaps used in a manner which differs from that observed in agamids.

In October 1993, at a field site 60 km S of Darwin, NT, Australia, I observed a trail of green ants (*Oecotsylla smaragolia*) on the ground, travelling in a northward direction. They occasionally were transporting insect prey. Waiting 5 cm from the ant trail

were 1 male and 2 female adult *C. munda*, about 1 m apart. As the ants moved their insect prey along the line a lizard would dash over and pluck it from an ant, move about 30 cm from the ant trail and consume the prey. Piracy of prey items from the ants by *C. munda* was observed on all four days I was at this site. On one occasion a fight developed between the two females when one animal attempted to swap positions. Piracy of prey from ants was observed at another field site on a single day (pers. obs.) and at other sites (M. Guinea, pers. comm.). Tail waving was observed on many occasions and did not appear related to prey piracy.

CNEMIDOPHORUS GULARIS GULARIS (Texas Spotted Whiptail). **MAXIMUM SIZE.** The maximum size for *Cnemidophorus g. gularis* given by Conant and Collins (1991. A Field Guide to the Reptiles and Amphibians of Eastern and Central North America, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, xviii + 450 pp.) is SVL 3 1/2 in. (90 mm) and TL 11 in. (279 mm). The Tulane University Museum of Natural History contains a male specimen TU 22914 from 3.5 mi (5.6 km) north of Shamrock, Wheeler County, Texas collected by Robert R. Hollander on 14 May1987 which measures 105 mm (3 7/8 in.) SVL and 296 mm (1 13/16 in.) TL. The postantebrachial scales of the specimen appear somewhat larger than the usual postantebrachials of the race and a count of 97 granular scales near mid body where the ventral scute rows are widest is somewhat higher than the 93 previously reported by Conant and Collins (*op. cit.*). Somewhat farther forward the granular scute count is at least 112.

John W. Wright kindly verified the identity of the specimen.

GAMBELIA SILA (Blunt-nosed Leopard Lizard). **PREDATION.** Territoriality exhibited by male *Gambelia sila* (Montanucci 1965. Herpetologica 21:270–283; Tollestrup 1983. Z. Tierphyscol. 62:307–320) may expose these lizards to higher rates of predation than if they were secretive. Territoriality may also expose adult *G. sila* to some avian predators that might not be able to catch these lizards if they were hidden in vegetation. On the Elkhorn Plain in San Luis Obispo County, California, adult *G. sila* are conspicuous because they often bask on sparsely vegetated mounds of giant kangaroo rats (*Dipodomys ingens*; Germano and Williams, unpubl. data). Predators known to take *G. sila* include the San Joaquin coachwhip (*Masticophis flagellum ruddocki*), gopher snake (*Pituophis melanoleucus*), loggerhead shrike (*Lanius ludovicianus*), American kestrel (*Falco sparverius*), burrowing owl (*Athene cunicularia*), and roadrunner (*Geococcyx californianus*), and other snakes, birds, and mammals are suspected of being predators (Montanucci 1965. Herpetologica 21:270–283; Tollestrup 1979. Unpubl. Ph.D. diss., Univ. California, Berkeley). Here we report the observation of predation of *G. sila* by a bird previously not known to eat these lizards.

On 17 June 1994, we observed an act of predation on a *Gambelia sila* while we were censusing the perimeter of one of our plots on the Elkhorn Plain, California (Germano and Williams 1994. Northwestern Nat. 75:11–19). As we walked the perimeter to find marked lizards, we spotted a medium-sized male *G. sila* (estimated 100 mm SVL) on a kangaroo rat mound at about 1130 h (PDT). We approached the male with our pole and noose and were about 4 m from the lizard when we saw from the corner of our eyes movement and a large shadow coming from behind us. An instant later, we saw a prairie falcon (*Falco mexicanus*) catch the lizard in its talons, bank quickly to our right, and fly back by us. The falcon flew about 2 m off the ground for approximately 10 m until it was able to gain altitude. It continued flying with the lizard in its talons to the southwest towards the nearby Panorama Hills. This is the first recorded observation of predation of *G. sila* by a prairie falcon.

VARANUS GRISEUS (Desert Monitor Lizard). **REPRODUCTION.** Data on clutch size for monitor lizards from Middle Asia in general, and Kazakhstan in particular, have rarely been reported. On 21 June 1989 a road-killed female *Varanus griseus*, TL = 105 cm (47 cm SVL + 58 cm tail) was found near Sjutkent settlement, South Kazakhstan Region, Republic of Kazakhstan (67°40'E, 41°50'N). Dissection revealed 24 soft-shelled eggs (13 in the left oviduct, 11 in the right), eight of which were damaged. The eggs had an average size of 48.0 x 26.9 mm (46.0–52.0 mm x 26.0–28.0 mm, N = 16) and a mean mass of 20.4 g (N = 16).

The largest clutch size previously known for Middle Asian desert monitors (23 eggs) was recorded in a female of 99 cm TL (44 cm SVL + 55 cm tail) from the Surchan-Darja Region of Uzbekistan on 8 June 1949 (Bogdanov 1960. The Fauna of Uzbekistan, vol. 1 [in Russian]. Academy of Sciences of Uzbekistan, Tashkent. 115 pp.).

Boris Gubin (Institute of Zoology of the National Academy of Sciences, Kazakhstan) helped to measure the lizard.

SERPENTES

CORONELLA GIRONDICA (Southern Smooth Snake). **PREY SIZE.** *Coronella girondica* is a small colubrid with a total length usually < 70 cm. It is nocturnal and secretive, which probably accounts for it being one of the least known snakes in France (Saint Girons 1989. *In* J. Castanet and R. Guyetant (eds.), Atlas de Repartition des Amphibiens et Reptiles de France. Soc. Herp. Fr. p. 153). The snake's diet consists primarily of small lizards and occasionally small mammals. The following reptiles have been documented in the diet of *C. girondica*: *Hemidactylus turcicus, Tarentola mauritanica, Anguis fragilis, Chalcides bedriagai, C. chalcides, Acanthodactylus erythrurus, Psammodromus algirus, P. hispanicus, Podarcis bocagei, P. hispanica, P. muralis*, and *P. sicula* (Vericard and Escarre 1976. Mediterranea, Alicante 1:5–32).

On 5 August 1994, in the "Causse du Larzac," Millau, Aveyron Prov. France, we found a male *Coronella girondica* (SVL = 465 mm, mass = 40 g) feeding on an adult *Lacerta viridis*. The snake had already swallowed the head and body of the prey up to the point of the cloaca. Thus, the maximum circumference of the prey had passed the articulation of the snake's quadrates with the mandibles. When captured, the snake immediately regurgitated the prey. The lizard was still alive and regained full consciousness after 5 minutes. The total length of the *L. viridis* was 312 mm

(118 mm SVL + 194 mm tail length) and it weighed 30.5 g. The prey: snake mass ratio was therefore 0.76. This is an exceptionally high value for colubrids as Pough and Groves (1983. Amer. Zool. 23:443–445) reported maximum prey: snake mass ratios of 0.18 for a non-viper and 0.36 for a viper. This observation indicates that *C. girondica*, like its congener *C. austriaca*, is apparently able to feed on relatively large prey.

Submitted by **ROBERT JOORIS**, Laboratory of Ecology, State University Ghent, K.L. Ledeganckstraat 35, B-9200 Ghent, Belgium.

CROTALUS MOLOSSUS MOLOSSUS (Blacktail Rattlesnake). **MAXIMUM LENGTH.** On 23 August 1994, a male *Crotalus molossus molossus* was found entering a dead agave plant occupied by a radio telemetered female at our study site 2.5 mi. northwest of Portal, Cochise County, Arizona. Under isoflurane inhalation anesthesia, its measurements were 1330 mm (52.4 in.) total body length (TBL) (1241 mm SVL + 89 mm TL) and 1011 g body mass. Sex was confirmed by probing and the snake was released at the capture site the same day. Slides showing it extended next to a meter rule are on file at MVZ. Maximum TBL measured by Gloyd (1940. The Rattlesnakes, Genera *Sistrurus* and *Crotalus*, Chicago Academy of Sciences, Chicago, Illinois, vii + 266 pp) of 1250 mm for *C. m. molossus* was a male from Brewster County, Texas. Klauber (1972. Rattlesnakes, University of California Press, Berkeley and Los Angeles, California, 1533 pp.) indicated a maximum length of 1257 mm (49.5 in.). Shaw and Campbell (1974. Snakes of the American West, Alfred A. Knopf, New York, 332 pp.) give maximum length as 4.25 ft (51 in., 1295 mm) and Tennant (1984. Snakes of Texas, Texas Monthly Press, Inc., Austin, Texas, 561 pp.) referred to a specimen reported to be 52 in. (1321 mm) TBL from Kerr County, Texas.

Submitted by **DAVID L. HARDY, SR.**, 3905 Old Sabino Canyon Road, Tucson, Arizona 85715, USA, and **HARRY W. GREENE**, Museum of Vertebrate Zoology, University of California, Berkeley, California, 94720, USA.

EPICRATES CENCHRIA CENCHRIA (Brazilian Rainbow Boa). **MALE COMBAT.** The various studies, reviews, and discussions of male combat in snakes do not show that the boine *Epicrates cenchria* exhibits male combat (Carpenter 1986. Smithsonian Herp. Infor. Serv. 69:1–18; Ross and Marzec 1990. The Reproductive Husbandry of Pythons and Boas, Institute for Herpetological Research, Stanford, California, 270 pp.; Shine 1994. Copeia 1994:326–346). In this report, male combat is documented for the first time in *E. c. cenchria*. The following observations were made on three (2M:1F) captive specimens maintained in Toledo, Ohio (USA). These individuals (plus two other adult females) were maintained in a wooden enclosure (2.44 x 1.22 x 1.22 m) equipped with a plexiglass front and incandescent lighting. Air temperature was ca. 28°C. Substrate heat was supplied in the form of a heat pad (30–31°C). Water was provided ad libitum in a Rubbermaid dishpan container. On 9 January 1993, at 0955 h, it was observed that male 2 (SVL = 106 cm) and female 1 (SVL = 130 cm) were copulating; they remained in coitus until 1900 h (duration of coitus was at least 9 h). During this period, male 1 (SVL = 136 cm) did not interfere with the activities of the copulating pair. At 1915 h male 1 was observed next to the pair, which had remained in close physical contact, and began moving on top of male 2 in a jerky and erratic manner. He was then observed to tail-search the female's lower body and tail in what appeared to be attempts to attain a pre-coital posture. At this time male 2 began to move in a slow manner. Both males then moved out ca. 35 cm from this grouping, moving parallel to each other (ca. 12 cm apart). The males met side-to-side and then abruptly began to entwine from midbody to nape.

Within seconds they exhibited a vertical stance (at least one-third of their anterior trunk) that lasted several seconds, then both fell to the floor and quickly separated, going to the same side of the enclosure but did not interact with each another. The female was on the opposite side at this time, and was not approached by either male. Observations were terminated at this point, and a winner could not be determined. Male 1 was 30 cm larger in SVL (28.3% difference) then male 2. Although mass was not determined, male 1 had greater mass than male 2.

The following day, 10 January, at 1630 h, male 1 was observed copulating in the water container with the female, and during this time male 2 remained at the opposite side of the enclosure on the heat pad and did not change position the entire day. Observations were made on the trio and the other two females over the next several days. Although combat was not witnessed again, on several occasions male 1 would raise his head and anterior trunk in the presence of male 2. Further, male 1 was observed to push male 2 across the enclosure floor; he did not exhibit pushing behavior toward the three females. Based on these observations and the fact that male 1 was both longer and heavier, these acts were concluded to be indicators of dominance.

Male combat exhibited by *E. cenchria* was similar to combat behavior described in other boids (Barker et al. 1979. Copeia 1979:466–477; Ross and Marzec, *op. cit.*), particularly its West Indian congeners, such as *Epicrates inornatus* (Huff 1978. Int. Zoo Ybk. 18:96–97) and *E. angulifer* (Tolson 1983. *In* D. L. Marcellini (ed.), Sixth Annual Reptile Symposium, pp. 285-293, Zoological Consortium, Inc., Thurmont, Maryland). Tolson (*op. cit.*) reported body (coil) shoving between male *E. angulifer* that seems similar to *E. cenchria* reported here. Further, like in *E. angulifer*, dominance could not be established conclusively in *E. cenchria*. Because combat was brief, it could not be determined if pelvic spurs were used, especially since they are small in *E. cenchria*. Further, release of musk (Huff, *op. cit.*) was not detected and biting was not observed in *E. cenchria*.

We thank Trooper Walsh for his time in discussing with us male agonistic behavior in captive *E. cenchria* maintained at the National Zoo.

Submitted by **GORDON W. SCHUETT**, Department of Life Sciences, Arizona State University West, P.O. Box 37100, Phoenix, Arizona 85069-7100, USA, and **SCOTT P. SCHUETT**, 1820 Bigelow Street, Toledo, Ohio 43613, USA.

LAMPROPELTIS GETULA HOLBROOKI (Speckled Kingsnake). **OOPHAGY**. Anecdotal observations of *Lampropeltis getula* as a predator of turtle eggs have been previously reported. Wright and Bishop (1915. Snakes, Vol. II, Proc. Acad. Nat. Sci. Philadelphia, pp. 107–192) reported the eggs of the Florida cooter, *Pseudemys floridana* and *Kinosternon* sp. from *L. getula* from the Okefenokee Swamp, Georgia. Brown (1979. Brimleyana. 1:113–124) also reported turtle eggs from two *L. getula*. More recently, Knight and Loraine (1986. Brimleyana. 12:1–4) list the eggs of the family Kinosternidae, as well as *Chelydra* and possibly *Terrapene carolina* as prey items of *L. getula*. Here we report the first observation of predation by *L. getula* on the eggs of the yellow-blotched map turtle, *Graptemys flavimaculata*, a threat-

ened emydid turtle endemic to the Pascagoula River drainage system in Mississippi.

On 6 July 1994, a female *L. getula holbrooki* was observed feeding on the eggs of *G. flavimaculata* between 1245 and 1310 h CMT. The snake measured 119.3 cm SVL (135.1 cm TL) and weighed 750 g after regurgitation of eggs. The snake was observed digging a concentric hole 30 cm in diameter and 6 cm deep on a sandbar along the east bank of the west Pascagoula River near Vancleave, Mississippi. The substrate consisted of loose leaves and sand deposited on the sandbar during periods of high water. The snake moved its body in such a fashion to push the substrate outward toward the margin of the concentric hole. The head and anterior portion of the body were located in the turtle nest cavity during the 25 min duration before the snake was removed from the hole. After removal, one egg remained in the nest cavity. The color and flexibility of the egg shell indicated it was probably deposited earlier that morning. An additional 12 ruptured eggs were later found regurgitated in the snake bag in which the snake was kept. Six of the eggs were regurgitated approximately 20 min after capture, and the remaining six 3 days later. Clutches of *G. flavimaculata* range in size from 3–9 (mean = 4.9) (R. Brauman, unpubl.) and therefore the 12 eggs probably represent predation by this snake on more than one clutch. Only one other *L. getula holbrooki* has been captured on a sandbar in the study area, and therefore the impact of predation by this species on *G. flavimaculata* nests is not known.

We thank Dr. Robert Jones and the Mississippi Department of Wildlife, Fisheries and Parks for their support of a larger study of the reproductive biology and nesting ecology of *G. flavimaculata* during which this observation was made.

Submitted by **ROBERT J. BRAUMAN** and **RICCARDO A. FIORILLO**, Department of Biological Sciences, Southeastern Louisiana University, Hammond, Louisiana 70402, USA.

MASTICOPHIS TAENIATUS TAENIATUS (Desert Striped Whipsnake). **ELEVATION RECORD**. The highest elevation reported for *Masticophis t. taeniatus* is 9360 ft (2851 m), based on MVZ 64131 collected on Rodgers Peak, Panamint Mts., Inyo Co., California (Papenfuss 1986. *In* C. A. Hall, Jr., and D. J. Young, eds., Natural History of the White-Inyo Range, Eastern California and Western Nevada and High Altitude Physiology: University of California, White Mountain Research Symposium, pp. 129–136. White Mtn. Res. Sta., Bishop, California; Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. 2nd ed., Houghton Mifflin Co., Boston, Massachusetts. 336 pp.). On 22 July 1994 a specimen of this species (body length 90 cm) was found on a southwestern slope at an elevation of 10,100 ft (3077 m) at Schulman Grove, White Mountains, Inyo Co., California (Inyo National Forest, T6S, R35E, Sec. 31; ca. 10 map mi. E of Bishop). The snake was active at 1130 h in an area dominated by Great Basin sagebrush (*Artemisia tridentata*) at the foot of a forest of bristlecone pine (*Pinus longaeva*). Specimen identification was confirmed by R. W. Hansen based on photographic vouchers. This record extends the elevational distribution by 700 ft (213 m).

Submitted by **ANTON H.P. STUMPEL**, Department of Animal Ecology, Institute for Forestry and Nature Research (IBN-DLO), Postbus 23, 6700 AA Wageningen, The Netherlands.

REGINA GRAHAMI (Graham's Crayfish Snake). **REPRODUCTION**. On 19 August 1993, Colorado River Municipal Water District (CRMWD) personnel set galvanized minnow traps for Concho water snakes (*Nerodia harteri paucimaculata*) in the drying pools of Elm Creek, Runnels County, Texas. The Elm Creek location (5.1 km N of Ballinger; 20.3 river km from the Colorado River) is a permanent monitoring site for *N. harteri*, and a perennial tributary of the Colorado River. On 20 August, between 0930 and 0945 h, a total of four snakes were captured (2 adult (male and female) *Nerodia erythrogaster transversa*; 1 adult female *N. harteri* with 6 embryos, and 1 adult female *Regina grahami* with 6+ embryos). The *R. grahami* was retained and brought back to the CRMWD Field Laboratory for observation.

At 0730 h on 3 September 1993, there were no neonate *R. grahami* in the vivarium, but by 1630 h the female (SVL 731 mm, tail 153 mm, mass 248 g) gave birth to 10 neonates and one infertile mass. A review of the literature indicates wide variation in the number of young per litter; however, the majority of reports range between 10 and 15 (Anderson 1942. Bull. Chicago Acad. Sci. 6(11):203–222; Beyer 1898. Am. Nat. 32:17–24; Branson 1904. Kansas Sci. Bull. 2(13):353–430; Conant and Bridges 1942. What Snake Is That? D. Appleton-Century. New York. 163 pp.; Clark 1949. J. Tennessee Acad. Sci. 24:244–261; Hudson 1942. Univ. Nebraska Conserv. Bull. 24. 126 pp.; Kofron 1979. Herpetologica 35:44–50; Seigel 1992. J. Herpetol. 26:32–37; Schmidt and Davis 1941. Field Book of Snakes of the United States and Canada. G. P. Putnam's Sons. New York. 365 pp.; Strecker 1926. Baylor Univ. Mus. Contri. 4:3–11). Wright and Wright (1957. Handbook of Snakes of the United States and Canada. Comstock Publ. Assoc., Cornell Univ. Press, Ithaca, N.Y., xviii + 1103 pp.) recorded six as the minimum number and 25 as the maximum number of young per litter. Hall (1969. Am. Midl. Nat. 18.156–163) reported a mean of 15 young per litter. Other reports ranged from 3 to 39 eggs, embryos, and/or neonates (Anderson 1965. The Reptiles of Missouri. Univ. Missouri Press. 330 pp.; Hall, *op. cit.*; Kennedy 1964. Texas J. Sci. 16:210–215; Kofron and Dixon 1980. Southwest. Nat. 25:107–109; Miner 1959. Herpetologica 15:234; Ramsey 1954. Herpetologica 10:188).

Of the 10 neonates born in our lab, 7 were females and 3 were males. Hall (*op. cit.*) reported a sex ratio of 1:1 for both adults and young. His method for determining the sex for neonates was by examining individuals born in captivity and by sexing unborn snakes from preserved specimens. Our methodology followed that of Seigel (*op. cit.*). But Hall (*op. cit.*) also stated the sex ratio of offspring was skewed in favor of females, and there was evidence of sexual dimorphism among neonates, with males larger than females in body length but not body mass. Our data support Hall's (*op. cit.*) findings in that regard. Measurements of the 3 neonate males were: TL range = 285–294 mm, mean = 290.7 mm, SD = 4.0; mass range = 5.3–5.7 g, mean = 5.5 g, SD = 0.2; neonate females: TL range = 273–278 mm, mean = 276.4 mm, SD = 4.0; mass range = 5.3–5.9 g, mean = 5.5 g, SD = 0.2; overall litter measurements were: SVL range = 225–238 mm, mean = 229 mm, SD = 5.0; tail length range = 48–56 mm, mean = 51.7 mm, SD = 2.4; mass range = 5.3–5.9 g, mean = 5.5 g, SD = 0.2. After parturition the adult female weighed 158.5 g. The total litter mass (excluding the infertile mass) was 55.3 g and the relative clutch mass (RCM = ratio of total litter mass to postpartum female mass + total litter mass) was 0.259. This compares to a RCM of 0.300 for *Nerodia rhombifer* (Plummer 1992. Copeia 1992:1096–1098.) and 0.295 for 22 species of viviparous colubrids (Seigel and Fitch,

1984. Oecologia (Berl.) 61:293–301). All the neonates sloughed immediately after birth. Hall (*op. cit.*) found well preserved spermatozoa in males captured as early as 9 April and as late as 1 October, while Kofron (1979, *op. cit.*) reported females ovulated from late April through the third week of June. Assuming a 3-month period of gestation (Betz 1963. Copeia 1963:692–697), ovulation of this *R. grahami* probably occurred in early June.

During the past seven years, we have captured, measured, weighed, sexed, and released five *R. grahami* within the Elm Creek watershed: three snakes at this site; one 27.4 stream km upstream on Mud Creek, an intermittent tributary; and one on the northwestern shore of Lake Winters, in Runnels County. Tinkle and Knopf (1964. Herpetologica 20:42–47) collected a single *R. grahami* (Texas Tech 2908) at Ballinger, Texas and noted this record as evidence for a breeding population of this species well into western Texas. The rareness of this species in west and west-central Texas is probably attributed to this being the western periphery of its range, xeric conditions, and possibly food resource limitations. On 6 September 1993, the adult *R. grahami* and her litter were photographed and released at the original capture site.

We thank the Colorado River Municipal Water District for funding and facilities. Collections were made under the authority of the Texas Parks & Wildlife Department Scientific Permit No. SPR-790-208 to CRMWD. James R. Dixon reviewed an earlier version of this manuscript.

Submitted by **OKLA W. THORNTON, JR.**, and **JERRY R. SMITH**, Colorado River Municipal Water District, HCR 82, Box 4B, Leaday, Texas 76851, USA.

SEMINATRIX PYGAEA (Black Swamp Snake) **SIZE.** The record total length (SVL + tail length) for *Seminatrix pygaea* given in Conant and Collins (1991. Field Guide to Reptiles and Amphibians, Houghton Mifflin Company, Boston, Massachusetts, 450 pp.) is 47.0 cm based on a specimen described by Palmer and Paul (1963. Herpetologica 19:219–221). Their specimen was a female with an incomplete tail, having only 18 subcaudals. The record size given for *S. pygaea* in Ernst and Barbour (1989. Snakes of Eastern North America. George Mason University Press, Fairfax, Virginia) was erroneously printed as 65.4 cm total length, but should have read 46.5 cm (Carl Ernst, pers. comm.).

Here we report a gravid female *S. pygaea* (SREL specimen #3422) with a total length of 55.5 cm (48.5 cm SVL + 9.0 cm tail; mass = 68.4 g), exceeding the previous record by 8.5 cm. The female's length through subcaudal 18 was 51.2 cm.

This female and another gravid female *S. pygaea* (SREL specimen #3423) with a total length of 44.4 cm (37.0 cm SVL + 7.4 cm tail; mass = 43.0 g) were regurgitated simultaneously by a *Lampropeltis getula* (common kingsnake; 91.6 cm SVL, 12.7 cm tail) captured on 2 May 1994 at Ellenton Bay on the Savannah River Site near Aiken, South Carolina. The kingsnake was released at the capture site.

We thank Roger Conant for providing the source of the original record and Mark Mills for preserving the *Seminatrix* specimens. J. Whitfield Gibbons and Vincent J. Burke made helpful comments on the manuscript. Research support and manuscript preparation were provided by contract DE-AC09-765ROO-819 between the University of Georgia and United States Department of Energy.

Submitted by **CHARLES A. KEAN** and **TRACEY D. TUBERVILLE**, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in volume 26, number 1.

CAUDATA

AMBYSTOMA CINGULATUM (Flatwoods Salamander). USA: FLORIDA: Holmes Co: Sec. 9, T5N, R14W, 8.8 air km NNE Bonifay. 24 February 1993. John G. Palis. UF 95951; Okaloosa Co: Sec. 17, T2S, R25W, 9 air km ENE Navarre. 18 January 1993. John G. Palis and Kelly J. Irwin. UF 95950; Walton Co: Sec. 16, T1N, R17W, 3 air km N Bruce. 28 February 1993. John G. Palis. UF 95952. All verified by Paul E. Moler. New county records filling gap in range (Moler 1992, Rare and Endangered Biota of Florida, vol. 3, Amphibians and Reptiles. Univ. Press Florida, Gainesville, 291 pp.).

Submitted by **JOHN G. PALIS**, Rural Route 1, Box 258, Tell City, Indiana 47586, USA.

AMBYSTOMA MACULATUM (Spotted Salamander). MASSACHUSETTS: Dukes Co: Martha's Vineyard, Edgartown. 19 November 1994. Arnold Brown and Vernon Laux. Verified by Jose Rosado. MCZ A-116268. Found runover in a parking lot. Despite a plethora of exciting stories and putative sight records, I had to "...await an actual specimen" from this island for two decades (Lazell 1976, This Broken Archipelago: Cape Cod and the Islands, Amphibians and Reptiles. New York Times Book Co., p. 56). The location, ca. 300 m south of the only probable breeding pond in the vicinity, and the size—49 mm SVL—hint at a record-late, very large, dispersing metamorph. I am indebted to Ilan Keith for salvaging the specimen.

Submitted by **JAMES LAZELL**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835, USA.

GYRINOPHILUS PALLEUCUS (Tennessee Cave Salamander). USA: TENNESSEE: Warren Co: small spring feeding Collins River, ca. 0.25 km upstream Rt. 127 crossing. 20 February 1992. B. T. Miller. Middle Tennessee State University (MTSU 154C, on permanent loan to National Museum of Natural History). Verified by A. Wynn. Postmetamorphic adult specimen. In contrast to the other reports of naturally metamorphosed *G. palleucus*, this individual was robust and in good health at time of capture. County record decreasing the suspected hiatus in distribution between populations occurring in the inner central basin of Tennessee (Rutherford and Wilson counties) and those in the southern Eastern Highland Rim (Miller and Walther 1994, Herpetol. Rev. 25:73; Redmond 1985, A Biogeographic Study of Amphibians in Tennessee, Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.; Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

NOTOPHTHALMUS PERSTRIATUS (Striped Newt). USA: GEORGIA: Baker Co: Joseph W. Jones Ecological Research Center: ca. 0.4 km N Mimsville and E of County Road 1630 (31°17'7"N, 78°31'44"W). 7 March 1994. S. Smith, L. V. LaClaire, R. N. Smith, and J. Palis. Verified by Roy McDiarmid. USNM 335058, 335059. Two adult males collected in a small

cypress limesink depression pond contiguous with the longleaf pine/wiregrass uplands. New county record, extends range in Georgia west of the Flint River, ca. 115 km from nearest county record (Mecham 1967, Cat. Am. Amphib. Rept. 38.1–38.2).

Submitted by **LINDA V. LACLAIRE**, U.S. Fish and Wildlife Service, 6578 Dogwood View Parkway, Jackson, Mississippi 39213, USA, **ROBERT N. SMITH** and **SCOTT SMITH**, Joseph W. Jones Ecological Research Center, Route 2, Box 2324, Newton, Georgia 31770, USA, and **JOHN PALIS**, Rural Route 1, Box 258, Tell City, Indiana 47586, USA.

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). USA: KANSAS: Linn Co: Marais des Cygnes Wildlife Area, NW 1/4 Sec. 27, T20S, R24E. 17 April 1994. Kelly J. Irwin. Verified by Joseph T. Collins. KU 222266 (eft). First voucher from Linn County in 44 years, confirming the record by Gloyd (1932, Pap. Michigan Acad. Sci. Arts Letters 125:389–409) for east-central Kansas. Found in association with one adult each of *Carphophis vermis* and *Diadophis punctatus* under a limestone rock on a southeast facing hillside in mature oak-hickory forest. A subsequent visit to the area on 22–23 April 1994 produced two more efts and four adults [1 male (KU 222262), 3 females] in breeding condition; these represent the second report of a breeding population (Gloyd 1932, *op. cit.*) in the Marais des Cygnes River valley of Kansas as mapped by Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin, Boston, Massachusetts, 450 pp.).

Submitted by **KELLY J. IRWIN**, 2218 West 2nd Street, Topeka, Kansas 66606, USA.

ANURA

BUFO ACHALENSIS (Sapito de Pampa de Achala). ARGENTINA: CORDOBA: Department Rio Cuarto, 19 km NW Alpa Corral (32°42'S, 64°42'W) on rocky place in summit ("pampa de altura") of Sierra de Comechingones (Cerro de Oro site). 28 February 1994. Luciano Javier Avila and José Waldemar Priotto. Verified by Ricardo A. Martori. Herpetological collection of Zoologia de Vertebrados, Departamento de Ciencias Naturales, Universidad Nacional de Rió Cuarto, Argentina (ZV-UNRC 2982 to 2987, 3195). Extends range ca. 120 km from Pampa de Achala and Cerro Los Gigantes populations (Cei 1972, Acta. Zool. Lill. 29:233–246) and confirms unvouchered published reports at "Comechingones" (Cei 1980, Monit. Zool. Ital., Mon. 2, Florencia, 609 pp.); cited also at La Carolina, Sierra de San Luis, 150 km W. [Giambelluca 1991, Bol. Asoc. Herp. Arg. 7(1):21–22].

Submitted by **LUCIANO JAVIER AVILA** and **JOSÉ WALDEMAR PRIOTTO**, Departmento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Est. Post. Nro. 9, C. P. 5800, Rio Cuarto (Córdoba), Argentina.

CERATOPHRYS CALCARATA (Horned Frog). VENEZUELA: ESTADO FALCON: Municipio Silva, Parque Nacional Morrocoy, Cerro Chichiriviche, Sector El Silencio, 280 m elev. 5 July 1989. Jorge Naveda and José Ochoa. Verified by Pedro Vernet. Colección de Anfibios y Reptiles, Instituto de Geografía, Universidad de Los Andes (ULABG) 3931. Easternmost record for the species (La Marca 1992, Cuadernos Geográficos 9:1–197).

Submitted by **ENRIQUE LA MARCA**, Universidad de Los Andes, Facultad de Ciencias Forestales, Instituto de Geografía y Conservación de Recursos Naturales, Apartado Postal 116, Mérida 5101-A, Venezuela, and **JORGE NAVEDA**, INPARQUES, Dirección Parques Nacionales, Apartado 76471, Caracas 1062-A, Venezuela.

CHIASMOCLEIS VENTRIMACULATA (NCN). BOLIVIA: COCHABAMBA: Provincia Chapare, 6.5 km N Chipiriri, 260 m, 16°45'S, 65°15'W. 15 February 1970. Thomas H. Fritts. Verified by William E. Duellman. KU 136316. First record for the country; nearest record published is Cuzco Amazónico, Madre de Dios, Perú, 12°35'S, 69°05'W (Duellman and Salas 1991, Univ. Kansas Mus. Nat. Hist. Occ. Pap. 143:1–13), ca. 600 km NW (airline). This is the sixth species in the family Microhylidae known from Bolivia (De la Riva 1990, Boll. Mus. reg. Sci. nat. Torino 8:261–319).

Submitted by **IGNACIO DE LA RIVA**, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA.

ELEUTHERODACTYLUS ANOLIREX (Robber Frog). VENEZUELA: ESTADO TACHIRA: Municipio Junín, Betania, 2300 m elev. 7 August 1980. Alfredo Paolillo. Museo de Historia Natural La Salle (MHNLS) 8370–8372; 14 August 1980. Alfredo Paolillo. MHNLS 8336–8337, 8340–8341, 8359–8360. All verified by John D. Lynch. First record for Venezuela; species was previously known from a few localities in the Departamento Norte de Santander, Cordillera Oriental, Colombia (Lynch 1983, Advances in Herpetology and Evolutionary Biology. Pp. 52–57). Extends species range ca. 65 km NE from type locality, making this the northernmost record for the taxon.

Submitted by **ENRIQUE LA MARCA**, Universidad de Los Andes, Facultad de Ciencias Forestales, Instituto de Geografía y Conservación de Recursos Naturales, Apartado Postal 116, Mérida 5101-A, Venezuela.

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: FLORIDA: Okaloosa Co: Eglin Air Force Base, 0.2 km E Range Road 259 and 1 km N U.S. Rt. 98 (T2S, R25W, NE 1/4 Sec. 17). 29 November 1994. J. B. Jensen. Verified by Paul Moler. Florida Museum of Natural History (UF 95352). Captured within the ecotone between mesic pine flatwoods and a shrub-dominated dome swamp. The locality is ca. 0.5 km from the nearest residential area. New county record for this introduced species (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA, and **JOHN G. PALIS**, Rural Route 1, Box 258, Tell City, Indiana 47586, USA.

HYLA BROMELIACIA (Treefrog). MÉXICO: CHIAPAS: Centro Piscícola "La pesca," Municipio Coapilla (17°07'49"N, 93°10'00"W), elev. 1650 m. 5 March–5 May 1994. T. Acero, J. Cruz, L. de la Cruz, A. Domínguez, R. Hernádez, M. Martínez, E. Pérez, and V. Rodas. Herpetological Collection, Intituto de Biología, Universidad Nacional Autónoma de México (IBH 08642–08649, 8 specimens) and Museo de Zoología de Chiapas (MZICACH 68–79, 12 specimens). Specimens were found on bromeliads in a pine-oak forest. First record for México; extends range ca 250 km NW along Sierra del Norte de Chiapas. Previous northernmost record was Sierra de los Cuchumatanes, Guatemala (Stuart 1943, Occ. Papers Mus. Zool. Univ. Michigan 471:1–28).

Submitted by **MATIAS MARTINEZ-CORONEL**, Museo Zoológico, Escuela do Biología, ICACH, Apartado Postal 57, Tuxtla Gutiérrez, Chiapas, México, **AURELIO RAMIREZ-BAUTISTA**, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Apartado Postal 70-

153, 04510 México Distrito Federal, México, and **ROBERTO VIDAL-LOPEZ**, Museo Zoológico, Escuela de Biología, ICACH, Apartado Postal 57, Tuxtla Gutiérrez, Chiapas, México.

HYLA GRATIOSA (Barking Treefrog). USA: TENNESSEE: Carroll Co: Milan Army Ammunition Plant, 0.40 km S Rt. 104 on MAAP road paralleling Lavinia Atwood Road, 35°54'15"N, 88°40'03"W. 6 June 1994. B. T. Miller. Middle Tennessee State University (MTSU 80A); Rt. 104, ca. 1.4 km W jct. Lavinia Atwood Road on side of MAAP security building (35°54'24"N, 88°39'57"W). 28 June 1994. B. T. Miller. Both verified by A. Floyd Scott. New county record that decreases suspected distributional hiatus in western Tennessee (Redmond 1985, A Biogeographic Study of Amphibians in Tennessee, Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.; Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA, and **DAVID L. CAMPBELL**, Director of Stewardship, The Nature Conservancy, 2002 Richard Jones Road, Suite 304-C, Nashville, Tennessee 37215, USA.

HYLA RANICEPS (NCN). ARGENTINA: PROVINCE OF BUENOS AIRES: Delta of Paraná River (34°09'S, 58°31'W). 3 March 1984. Néstor G. Basso. Verified by J. D. Williams. Museo de La Plata (MLP.A. 909). First record for province and the southernmost record for the species [Gallardo 1964, Neotropica 10 (31):23–28; Cei 1980, Monitore. zool. ital. (NS) Monogr. 2. 609 pp.].

Submitted by **NÉSTOR G. BASSO**, Instituto de Limnología "Dr. Raúl A. Ringuelet," Casilla de Correo 712, 1900 La Plata, Argentina.

ISCHNOCNEMA QUIXENSIS (NCN). BRAZIL: AMAZONAS: Municipality of Eirunepé, Penedo, right bank of Jurua River (70°45'W, 6°50'S). 29 August 1991. Claude Gascon. Verified by James P. Bogart. Instituto Nacional de Pesquisas da Amazônia (INPA 2394, 2471). First record for Brazil. Closest known recorded locality for this species is Madre de Dios, Peru [Rodriguez et. al. 1993, Pub. Mus. Hist. Nat. UNMSM (A) 45:1–22]. Other localities where this species was collected in Amazonas are: Municipality of Eirunepé, Condor, left bank of Jurua River (70°51'W, 6°45'S). 18 September 1991. INPA 2629, 2673–76, 2689, 2732, 2816–17, 2928, 3000, 3009; Municipality of Itamarati, Barro Vermelho, left bank of Jurua River (68°46'W, 6°28'S). 18 October 1991. INPA 3131, 3138, 3144, 3187, 3243, 3266, 3274, 3293, 3333, 3337, 3421, 3459, 3475, 3515–16; Municipality of Itamarati, Altammira, right bank of Jurua River (68°54'W, 6°35'S). 16 November 1991. INPA 5040, 5230; Municipality of Jurua, Vai-Quem-Quer, right bank of Jurua River (66°01'W, 3°19'S). 2 May 1992. INPA 4822, 4846, 4982, 4987, 4990, 5273, 5299; JMunicipality of Jurua, Vira-Volta, left bank of Jurua River (66°14'W, 3°17'S). 28 May 1992. INPA 5613, 5805; ACRE: Municipality of Cruzeiro do Sul, Nova Vida, right bank of Jurua River (72°49'W, 8°22'S). 13 March 1992. INPA 4599, 4617, 4650; Municipality of Cruzeiro do Sul, Sobral, left bank of Jurua River (72°49'W, 8°22'S). 8 March 1992. INPA 4420, 4440, 4455, 4457, 4532, 4539, 4552, 4559–60, 4566, 4644, 4679, 4690–91; Municipality of Cruzeiro do Sul, Porongaba, right bank of Jurua River (72°47'W, 8°40'S). 18 February 1992. INPA 4254, 4396.

Submitted by **CLAUDE GASCON**, Ecologia/INPA, CP 478, 69011-970 Manaus, Amazonas, Brazil.

ODONTOPHRYNUS ACHALENSIS (Escuercito de Pampa de Achala). ARGENTINA: CORDOBA: Department Rio Cuarto, 19 km NW Alpa Corral (32°42'S, 64°42'W) on rocky place in summit ("pampa de altura") of Sierra de Comechingones (Cerro de Oro site). 28 February 1994. Luciano Javier Avila and José Waldemar Priotto. Verified by Ricardo A. Martori. Herpetological collection of Zoologia de Vertebrados, Departamento de ciencias Naturales, Universidad Nacional de Rio Cuarto, Argentina (ZV-UNRC 2988 to 2993, 3196). Extends range ca. 120 km from population on Pampa de Achala, Department Calamuchita. [Di Tada et al. 1984, Hist. Nat. 4(17):149–155].

Submitted by **LUCIANO JAVIER AVILA** and **JOSÉ WALDEMAR PRIOTTO**, Departmento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Est. Post. Nro. 9, C. P. 5800, Rio Cuarto (Córdoba), Argentina.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog, Rana Platanera). PUERTO RICO: Trujillo Alto: Cooperativa de la Vivienda, Avenida Periferal, Ciudad Universitaria. 9 March 1995. Neftalí Rios López. Verified by William E. Duellman. KU 222212–15. First record for the eastern part of Puerto Rico; extends range ca. 100 km to the west. Previous records were limited to the northwestern part of the Island (Isabela-Quebradilla area) where the introduction occurred in the 1950s (Rivero 1978, Los Anfibios y Reptiles de Puerto Rico. Editorial Universitaria, U. P. R., San Juan. 152 pp.; Schwartz and Henderson 1991, Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. 720 pp.; Thomas and Joglar, The Herpetology of Puerto Rico, Past, Present and Future. Ann. New York Acad. Sci., *in press*). Four adults were captured— two breeding males at border of non-permanent pond and a non-breeding male and a female perched over tubes of cyclone fence bordering a basketball court. It is possible that this frog is established in Río Piedras and other areas in the San Juan

metropolitan area. Although the origin of the northeastern population is unknown, the most probable source is the population in northwestern Puerto Rico observed on 29 May 1992 at Barrio Guaniquilla, Aguada (R. Joglar, pers. obser.). It is possible that the species has expanded its range and is now more widely distributed in the Island.

Submitted by **RAFAEL L. JOGLAR** and **NEFTALÍ RIOS LÓPEZ**, Universidad de Puerto Rico, Recinto de Río Piedras, Departamento de Biología, Apartado 23360, San Juan, Puerto Rico 00931-3360.

PHYLLOMEDUSA PALLIATA (NCN). BRAZIL: ACRE: Municipality of Cruzeiro do Sul, Nova Vida, right bank of Jurua River, (72°49'W, 8°22'S). 21 March 1992. Claude Gascon. Verified by James P. Bogart. Instituto Nacional de Pesquisas da Amazônia (INPA 4751, 4759). First record for Brazil; closest known recorded locality for this species is Madre de Dios, Peru (Rodriguez et. al. 1993, Pub. Mus. Hist. Nat. UNMSM (A) 45:1–22). Another locality where this species was collected is: ACRE: Municipality of Cruzeiro do Sul, Porongaba, right bank of Jurua River (72°47'W, 8°40'W). 16 February 1992. INPA 4195–6, 4285.

Submitted by **CLAUDE GASCON**, Ecologia/INPA, CP 478, 69011-970 Manaus, Amazonas, Brazil.

PHYZELAPHRYNE MIRIAMAE (NCN). BRAZIL: AMAZONAS: Municipality of Eirunepé, Condor, left bank of Jurua River (70°51'W, 6°45'S). 25 September 1991. Claude Gascon. Verified by W. Ron Heyer. Instituto Nacional de Pesquisas da Amazônia (INPA 2726, 2747). New record for Brazil; extends known distribution of this species more than 500 km west of Madeira River, Brazil (Heyer 1977, Papéis Avulsos de Zoologia 31:141–162). Other localities where this species was collected in Amazonas are: Municipality of Itamarati, Barro Vermelho, left bank of Jurua River (68°46'W, 6°28'S). 30 October 1991. INPA 3432, 3440; Municipality of Itamarati, Altammira, right bank of Jurua River (68°54'W, 6°28'S). 30 October 1991. INPA 3432, 3440; Municipality of Itamarati, Altammira, right bank of Jurua River (68°54'W, 6°35'S). 8 November 1991. INPA 3543; Municipality of Jurua, Vira-Volta, left bank of Jurua River (66°14'W, 3°17'S). 31 May 1992. INPA 5637.

Submitted by **CLAUDE GASCON**, Ecologia/INPA, CP 478, 69011-970 Manaus, Amazonas, Brazil.

PLEURODEMA KRIEGI (NCN). ARGENTINA: CORDOBA: Department Rio Cuarto, 19 km NW Alpa Corral (32°42'S, 64°42'W) on rocky place in summit ("pampa de altura") of Sierra de Comechingones (Cerro de Oro site). 28 February 1994. Luciano Javier Avila and José Waldemar Priotto. Verified by Ricardo A. Martori. Herpetological collection of Zoologia de Vertebrados, Departamento de ciencias Naturales, Universidad Nacional de Rio Cuarto, Argentina (ZV-UNRC 2981). Extends range ca. 100 km from southernmost population cited near Cerro Champaquí (site Tabaquillo), Department Calamuchita. [Barrio 1977, Physis 37(93):311–331].

Submitted by **LUCIANO JAVIER AVILA** and **JOSÉ WALDEMAR PRIOTTO**, Departmento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Est. Post. Nro. 9, C. P. 5800, Rio Cuarto (Córdoba), Argentina.

RANA CAPITO (Gopher Frog). USA: GEORGIA: Chattahoochee Co: Ft. Benning Military Reservation, ca. 200 m W Box Springs Road, 5.2 km N Shamanski Road. (89°39'08"N, 32°28'05"W). 17 February 1994. J. B. Jensen. Verified by Roy McDiarmid. USNM 335109, 335110. Eleven egg masses were observed attached to emergent vegetation in small, flooded borrow pit and a small portion of one mass was collected. Tadpoles were reared to the point of transformation to aid in positive identification. All survivors, excluding the preserved vouchers, were released to the pond of origin. New county record (Altig and Lohoefener 1983, Cat. Am. Amphib. Rept. 324.1–324.4).

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA, and **LINDA V. LaCLAIRE**, United States Fish and Wildlife Service, 6578 Dogwood View Parkway, Jackson, Mississippi 39213, USA.

SCAPHIOPUS HOLBROOKII HURTERII (Hurter's Spadefoot). USA: ARKANSAS: Baxter Co: 1.6 km W jct. Ark. Rts. 341–201 (on 341 ca. 3.2 km NW Norfork). 12 April 1991. Emily B. Langevin, Jessica Langevin and Nicholas Langevin. Verified (based on bony hump between eyes) by James M. Walker and Stanley E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 17587). One specimen collected 2100 h on road during light rain following a heavy rain. First record for county; located in a mapped hiatus in north-central part of state bordering Missouri (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.); indicates probable continuous distribution of species from eastern to western Arkansas.

Submitted by **JAMES M. WALKER** and **EMILY B. LANGEVIN**, Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA.

TESTUDINES

CHELYDRA SERPENTINA (Snapping Turtle). USA: COLORADO: Adams Co: Barr Lake, Barr Lake State Park. Date not recorded. Collected by state park staff. Verified by Richard L. Holland. UCM color slides 95–97. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, 131 pp.).

Submitted by **ROSANNE HUMPHREY**, **DAVID CHISZAR**, and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). Kentucky: Caldwell Co: W edge Dawson Springs off Rt. 62 on W bank of Tradewater River. 24 July 1994. T. W. Taggart, K. J. Irwin, S. L. Collins and J. T. Collins. Verified by Travis W. Taggart. KU 222235 (found dead; shell only). New county record (John MacGregor 1986, unpubl. maps). Specimen taken under 1994 Kentucky Scientific Collecting Permit issued to author.

Submitted by **JOSEPH T. COLLINS**, Natural History Museum, University of Kansas, Lawrence, Kansas 66045, USA.

STERNOTHERUS CARINATUS (Razorback Musk Turtle). USA: ALABAMA: Mobil Co: Escatawpa River, 0.5 km upstream from U. S. Rt. 98 bridge (30°51' 45"N, 88°22'59"W). 5 October 1994. E. L. Blankenship. Auburn University (AUM photo collection PL103 and P104). 16 October 1994. M. Bailey and K. Schnuelle. AUM 33725. Verified by C. Guyer. New state record (Mount 1984, Vertebrate Wildlife of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 44 pp.). May represent a recent upstream expansion from the Mississippi portion of the drainage since surveys in the 1970s failed to detect this species in Alabama (R. Mount and G. Folkerts, pers. comm.).

Submitted by **EMMETT L. BLANKENSHIP**, P.O. Box 236, Shorter, Alabama 36075, USA, **MARK A. BAILEY**, Alabama Natural Heritage Program, 64 North Union Street, Montgomery, Alabama 36130, USA, and **KAREN SCHNUELLE** and **BRIAN HAUGE**, Department of Zoology and Wildlife Science, Auburn University, Alabama 36849, USA.

TRACHEMYS SCRIPTA SCRIPTA (Yellowbelly Slider). USA: NEW MEXICO: Socorro Co: Bosque del Apache National Wildlife Refuge, Unit 24E, 4 km SSW of refuge headquarters. 5 October 1994. J. N. Stuart. Verified by Michael E. Seidel. University of New Mexico Museum of Southwestern Biology (MSB 58206; melanistic male). First record of this non-native subspecies for New Mexico, but may not indicate establishment of *T. scripta scripta* in the Rio Grande drainage. *T. scripta elegans*, however, is introduced and apparently established in this New Mexico river. Prelimenary data suggest that *T. s. elegans* and native *T. gaigeae* are hybridizing at Bosque del Apache NWR (Seidel, pers. comm.; Stuart [*in press*], Bull. Maryland Herpetol. Soc.); the presence of *T. s. scripta* therefore may further compromise persistence of pure *T. gaigeae* at the refuge. Collected under U. S. Fish and Wildlife Service Special Use Permit No. 73599.

Submitted by **JAMES N. STUART**, National Biological Service, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131-1091, USA.

LACERTILIA

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: Nassau Co: Anderson's Chevron Station at jct. of I-95 and S.R. A1A/200 in Hero. 4 September 1994. Todd Campbell. Verified by A. C. Echternacht. UFMNH 95568. Two adult females (one collected) and one hatchling observed in a small patch of yaupon holly (*Ilex vomitoria*) shrubs. New county record; extends range ca. 30 km N of previous Jacksonville (Florida) record (Lee 1985, Copeia 1985:182–194). The owner has observed brown anoles for the last three years, but the station regularly sells potted citrus and ornamental plants from South Florida. It is not clear whether these individuals represent a persistent, reproducing population or a regular influx of propagules from nursery vegetation. None was found in adjacent developments. Duval Co: Jacksonville Beach, K-Mart at jct. of U.S. A1A and S.R. 202. 4 September 1994. Todd Campbell. Verified by A. C. Echternacht. UFMNH 95566–95567 (adult male and adult female). Represents second published Duval County locality, ca. 16 km E of Jacksonville record (Lee, *op. cit.*). Ten adults and 15 juveniles observed basking in landscaping shrubs and on the curb. All lizards found within 30 m of K-Mart Garden Center; none found in adjacent developments. This is very likely an established breeding population.

Submitted by **TODD S. CAMPBELL** and **JOSHUA T. HAMMONTREE**, Department of Zoology, University of Tennessee, M313 Walters Life Sciences Building, Knoxville, Tennessee 37996-0810, USA.

ANOLIS SAGREI (Brown Anole). USA: GEORGIA: Lowndes Co: Valdosta, Best Western King of the Road Motel, I-75 at U.S. Rt. 84. First record for Georgia. This site has been searched intensively at least once a year since June of 1983 in connection with another project. Brown anoles were first observed on 18 July 1987 when 2 adult males, 1 adult female, several hatchlings, and hatched eggs were seen on the east side of the motel across the drive from the office. An intensive search revealed no others in the vicinity. By 24 July 1988, adult males, females, and juveniles were found on the ground and walls around the entire motel, and the lizards have been observed at the locality every year through 1994. A single adult male (University of Tennessee Vertebrate Zoology Collection No. 5436) was obtained by Echternacht on 30 May 1992 to validate the locality (Georgia Department of Natural Resources Scientific Collecting Permit 29-No. 000088 issued 11 May 1992). Verified by Julian C. Lee.

Submitted by **A. C. ECHTERNACHT, M. A. WILSON, E. J. MICHAUD**, and **DAN M. MACDONALD**, Department of Zoology, University of Tennessee, Knoxville, Tennessee 37996-0810, USA.

ANOLIS SAGREI (Brown Anole). USA: GEORGIA: Camden Co: Georgia Welcome Center on I-95, ca. 2 km N of the Florida-Georgia border. 4 September 1994. Todd Campbell. Verified by A. C. Echternacht. University of Georgia Museum of Natural History (UGAMNH 24852–24853). Captured two adult males and observed two females in dense yaupon holly and other landscaping shrubs. New county record; extends range ca. 46 km N of Jacksonville (Florida) record (Lee 1985, Copeia 1985:182–194). It is not clear if this is an established breeding population or represents recent propagules from landscaping plants obtained from Florida. Glynn Co: Brunswick, Mountasia Fantasy Golf Course at Brunswick Mall. 5 September 1994. Todd Campbell. Verified by A. C. Echternacht. UGAMNH 25854–25855. Two adult males captured, 12 more males and two females observed within shrubs and tropical plants among an artificial landscape of molded concrete and flowing water. New county record; extends range ca. 100 km N of Jacksonville (Florida) record (Lee, *op. cit.*). This is very likely an established population. The owners indicated these lizards have been present since the establishment of the course three years ago. Glynn Co: St. Simons Island, Ace Garden Center on Demere Road between Sea Island Drive and Retreat Road. 5 September 1994. Todd Campbell. Verified by A. C. Echternacht. UGAMNH 24851. One small female captured and one adult female observed near greenhouse and outdoor nursery; extends range ca. 100 km N of Jacksonville (Florida) record (Lee, *op. cit.*). May represent recent propagules from Florida nursery vegetation. Lowndes Co: Georgia Welcome Center on I-75, ca. 5 km N of Florida-Georgia border. 22 August 1994. Todd Campbell and Joshua Hammontree. Verified by A. C. Echternacht. UGAMNH 5432. One adult female collected and one individual of undetermined sex observed in landscape shrubs on the west side of the main building. Represents the second record for this species in Lowndes County, ca. 30 km S of original Valdosta (Georgia) record (Echternacht et. al. 1995, Herpetol. Rev. 26:107). These are likely recent propagules from Florida nursery vegetation. Cook Co: Adel, Howard Johnson Hotel on Rt. 37 at I-75. 22 August 1994. Todd Campbell and Joshua Hammontree. Verified by A. C. Echternacht. UGAMNH 25857–25858. Two adult males collected and four other individuals (unknown sex) observed. New county record; extends range ca. 34 km N of the Valdosta (Georgia) record (Echternacht et. al., *op. cit.*). May represent a small but established breeding population. Tift Co: Tifton, Ramada Inn on Rt. 82/319 at I-75. 22 August 1994. Todd Campbell and Joshua Hammontree. Verified by A. C. Echternacht. UGAMNH 25859. Young male collected, adult male observed in landscape shrubs around main building of the hotel. New county record; northernmost record for this species, extending its range ca. 70 km N of Valdosta (Georgia) record (Echternacht et. al., *op. cit.*). This was the only individual observed, and likely represents a recent propagule.

Submitted by **TODD S. CAMPBELL** and **JOSHUA T. HAMMONTREE**, Department of Zoology, University of Tennessee, M313 Walters Life Sciences Building, Knoxville, Tennessee 37996-0810, USA.

ANOLIS SAGREI (Brown Anole). USA: TEXAS: Nueces Co: Corpus Christi, South Padre Island Drive and Woodlawn Drive, 27°41'57"N, 97°21'13"W. 11 March 1995. P. J. Krusling. Verified by J. Davis. Cincinnati Museum of Natural History (CMNH 4206). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **PAUL J. KRUSLING** and **JOHN W. FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA, and **JODI PATTERSON,** University of Outreach, Texas A&M University at Corpus Christi, 6300 Ocean Drive, Corpus Christi, Texas 78412, USA.

Below is a corrected version of a note previously published in Herpetol. Rev. 25(4):164.

BASILISCUS BASILISCUS BARBOURI (Basilisk). VENEZUELA: ESTADO MÉRIDA: Distrito Campo Elías: Ejido, La Quebrada, sector Saladito, inmediaciones del Instituto Universitario Tecnológico de Ejido, 1200 m. 13 September 1993. Tulio Enrique Salazar Ruíz. Verified by Pascual J. Soriano M. Colección de Anfibios y Reptiles, Núcleo de Biogeografía de Montaña, Instituto de Geografía y Conservación de Recursos Naturales de la Universidad de Los Andes (ULABG 3426). The subspecies was first reported for the Venezuelan Andes, without indication of museum numbers, from "Estado Mérida: Río Chama," and "Estado Táchira: Palmira, Rio Tarbes" (Torbes?), by Donoso-Barros [1968, Caribbean J. Sci. 8(3–4):113]. ULABG voucher specimen is the first documented record for the Venezuelan Andes, extending the range ca. 400 km SE of the type locality. It is a female bearing pale throat markings that differ from those exhibited by Sierra de Perijá female specimens reported by La Marca as *Basiliscus basiliscus* (1987, Herpetol. Rev. 18:57; and 1987, 37a. Conv. Anual AsoVAC, noviembre 1987:267). Sierra de Perijá specimens have been identified either as *Basiliscus basiliscus basiliscus* by Donoso-Barros (*op. cit.*) or as *Basiliscus basiliscus barbouri* by Viloria and Calchi (1993 Biollania 9:42). Throat markings should be investigated as a potential diagnostic character for the subspecies, since most keys, like those of Peters and Donoso-Barros (1970 Bull. U.S. Natl. Mus. 297) and Gorzula (1978 Serie Boletín Técnico M.A.R.N.R., DG 11 A/BT/01/78) rely solely on male crest differences. One of us (JJGM) observed another specimen (not collected, but documented with color photograph taken on 26 August 1991 and filed in ULABG under number 3427) at Río Albarraegas, sector Belensate, 1400 m, Distrito Libertador, Estado Mérida. Several other observed specimens indicate that the subspecies is distributed along the Albarregas River at 1100 to 1600 m. from sector Belensate to the Urbanización Los Curos in the city of Mérida.

We thank Tulio Enrique Salazar Ruíz for collecting and donating the specimen to ULABG. Search partially funded by grant CDCHT C-564-92A of the Universidad de Los Andes, Mérida.

Submitted by **ENRIQUE LA MARCA**, Instituto de Geografía y Conservación de Recursos Naturales, Universidad de Los Andes, Apartado 116, Mérida 5101-A, Venezuela, and **JUAN JOSÉ GARCIA MILANO**, Laboratorio de Invertebrados de Los Andes, Urbanización Humboldt, Bloque 5, Edificio 02, Apartamento 0102, Mérida 5101, Venezuela.

ELGARIA KINGII (Madrean Alligator Lizard). MÉXICO: JALISCO: Autlán, Reserva de la Biósfera Sierra de Manantlán, on Rincón de Manantlán, in pine forest, elev. 1500 m. 21 June 1988. Luis I. Iñiguez-Dávalos. Verified by Fernando Mendoza Quijano. Museo de Zoología, Fac. de Ciencias, UNAM (MZFC 6003). Extends range of the species 98 km to the south (Webb 1970, Cat. Amer. Amph. Rept. 97.1–97.4); Cuautitlán, Reserva de la Biósfera Sierra de Manantlán, Cuzalapa, 4 km N El Durazno, in pine forest, elev. 880 m. 23 July 1988. Luis I. Iñiguez-Davalos. Colección Zoológica Laboratorio Natural Las Joyas (LNLJ 111). Extends range of the species 108 km to the south (Webb, *op. cit.*). COLIMA: Minatitlán, Reserva de la Biósfera Sierra de Manantlán, Km 2.2 to El Terrero, Minatilán, Colima, in tropical deciduous forest, elev. 1090 m. 20 November 1993. Alicia Loeza-Corichi. Colección Zoológica Laboratorio Natural Las Joyas (MZFC 6813). New state record for Colima; previously recorded from northern Jalisco (Webb, *op. cit.*).

Submitted by **ALICIA LOEZA-CORICHI,** Laboratorio Natural Las Joyas, Universidad de Guadalajara, México, and **OSCAR FLORES-VILLELA**, Museo de Zoología, Fac. de Ciencias, UNAM, Apartado Postal 70-399, México Distrito Federal 04510, México.

EUMECES LATICEPS (Broadhead Skink). USA: KANSAS: Linn Co: Marais des Cygnes National Wildlife Refuge, NW 1/4 Sec. 20, T21S, R25E. 16 April 1994. Kelly J. Irwin, Suzanne L. Collins, and Joseph T. Collins. Verified by John Simmons. KU 222264. Adult male specimen; corroborates the county record originally mapped by Collins (1982, Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356), which was based upon a record (Anderson 1950, Herpetologica 6:53) that had since been lost and was deleted from the range map in Collins (1993, Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 13:1–397).

Submitted by **KELLY J. IRWIN**, 2218 West 2nd Street, Topeka, Kansas 66606, USA.

OPHISAURUS ATTENUATUS (Western Slender Glass Lizard) KANSAS: Kiowa Co: Anchor D Ranch, Sec. 2, T30S, R16W. 30 May 1994. Garrett Jantz. KU Color Slide 11132. Verified by Travis W. Taggart. New county record; most southwesterly record in the state (Collins 1993, Amphibians and Reptiles in Kansas. Third Ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 13:1–397).

Submitted by **JOSEPH T. COLLINS**, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA.

XANTUSIA H. HENSHAWI (Granite Night Lizard). USA: CALIFORNIA: Riverside Co: Perris Valley, 2 km ENE jct. Perris Boulevard and Nandina Avenue, Sec. 33, T3S, R3W (33°52'N, 117°12'W). 30 January and 22 February 1995. Michael D. Wilcox, Stephen J. Myers, and Kent R. Beaman. Verified by Robert L. Bezy. Specimens were photographed and released on site. LACM voucher photograph PC1315. New location for the species in California; extends northern limit of range westward ca. 29 km (Lee 1976, Cat. Amer. Amphib. Rept. 189.1–189.2). In 1992 *X. h. henshawi* was also found at Double Butte, Riverside County (Sec. 19, T5S, R2W; 33°43'N, 117°08'W), ca. 18 km SE of the Perris Valley location. The species has also been observed at the NE end of the Bernasconi Hills, 7 km E of the Perris Valley location (D. Goodward, pers. comm.). These are the only known occurrences in Southern California away from the Peninsular Ranges.

Submitted by **MICHAEL D. WILCOX, STEPHEN J. MYERS**, and **KENT R. BEAMAN**, Tierra Madre Consultants, 1159 Iowa Avenue, Suite E, Riverside, California 92507, and **ROBERT L. McKERNAN**, San Bernardino County Museum, 2024 Orange Tree Lane, Redlands, California 92374, USA.

SERPENTES

CHERSODROMUS LIEBMANNI (Liebmann's Earth Runner). MÉXICO: OAXACA: municipality of Santa María Pápalo, Peña Verde, 1800 m elev. 28 February 1994. Luis Canseco Márquez. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 06842), female. Verified by Fernando Mendoza Quijano. First record for the state and a southern range extension of 118 km (airline) from Cuautlapan, Veracruz (Smith and Taylor 1945, Bull. U.S. Natl. Mus. 194:188). All specimens previously reported from Veracruz had a yellowish crossband behind parietal scales [Smith and Braestrup 1963, Herpetologica 18(4):233–240; Pérez-Higareda and Smith 1991, Inst. Biol. UNAM, México, 122 pp.] but the crossband is red on this specimen. This species was known previously only from the state of Veracruz [Smith 1943, Proc. U.S. Natl. Mus. 93(3169):343–504].

Submitted by **LUIS CANSECO-MAQUEZ** and **OSCAR FLORES-VILLELA**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (UNAM), Apartado Postal 70–399, México Distrito Federal 04510, México.

DRYMARCHON CORAIS MELANURUS (Palancacoate). VENEZUELA: ESTADO MÉRIDA: near San Rafael de Tabay, Hacienda El Progreso, ca. 9.5 km airline NE city of Mérida, 1800 m elev. 20 July 1986. María Martín and Pascual Soriano. Verified by María Martín. LAMPROPELTIS CALLIGASTER (Prairie Kingsnake). KENTUCKY: Christian Co: 5.6 mi S Dawson Springs on Ky. Rt. 109. 24 July 1994. S. L. Collins and J. T. Collins. Verified by Kelly J. Irwin. KU 222227 (DOR). Although not a county record, discovery extends range north into Western Coal Fields Province (Meade 1991, J. Tennessee Acad. Sci. 66:175–182). Specimen taken under 1994 Kentucky Scientific Collecting Permit issued to author.

Submitted by **JOSEPH T. COLLINS**, Natural History Museum, University of Kansas, Lawrence, Kansas 66045, USA.

LAMPROPELTIS GETULA HOLBROOKI (Speckled Kingsnake). IOWA: Appanoose Co: Wells Township, NE 1/4 Sec. 12, T67N, R16W. 2 October 1994. E. Tice. Verified by Joseph T. Collins. KU Color Slide 11169. New county record; Iowa endangered species that had not been verified in state for several years.

Submitted by **JEFFREY B. LECLERE**, 878 Galtier Street, St. Paul, Minnesota 55117, USA.

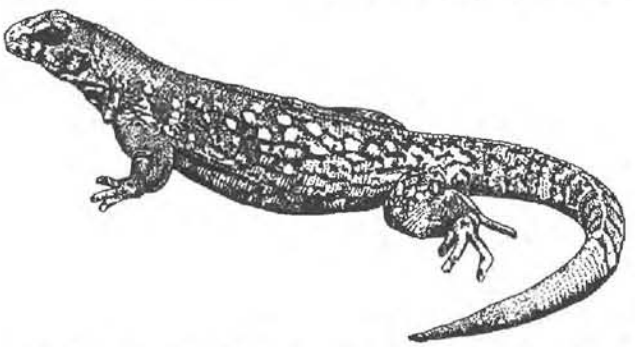
LAMPROPELTIS TRIANGULUM GENTILIS (Central Plains Milk Snake). USA: TEXAS: Sherman Co: 17.7 km S Texhoma. 21 November 1972. Collector unknown. Verified by Richard L. Holland. UCM 57038. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Press, College Station. 434 pp.). With nine (of nineteen) red rings on body split dorsally and twelve ventrally, allocation of the northern Texas panhandle population (Blair et al. 1994, Bull. Maryland Herp. Soc. 30:1–3) to this subspecies, instead of to *L. t. celaenops*, is supported.

Submitted by **KURT SCHAEFER**, Department of Biology, Panhandle State University, Goodwell, Oklahoma 73939, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

LEPTOTYPHLOPS DULCIS DISSECTUS (New Mexico Blind Snake). USA: OKLAHOMA: Texas Co: Goodwell. 15 May 1968. D. Jackson. Verified by Richard L. Holland. UCM 57036. First county record (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press, Norman, 370 pp.). An anomalous individual. The dorsals are numerous (229), as expected in the subspecies (Smith and Chiszar 1993, Bull. Maryland Herp. Soc. 29:143), and dorsals 5–8 are broader than the following scales, but the anterior supralabial is not split on either side, and no occipital is split. Its characters are intermediate relative to both subspecies, but it is from well within the range of *L. dulcis dissectus*.

Submitted by **KURT SCHAEFER**, Department of Biology, Panhandle State University, Goodwell, Oklahoma 73939, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). MÉXICO: PUEBLA: Municipality of Puebla, Puebla City (19°02'N, 98°12'W), 2150 m elev. 10 April 1993. Collected by Paul Davies. Escuela de Biología, Universidad Autónoma de Puebla (EBUAP-930033). Another specimen collected by Ana María Horán (EBUAP-930088). Both specimens verified by Fernando Mendoza Quijano. First records for the state and range extension of 105 km (airline) E from Morelos (Dixon and Hendricks 1979, Zool. Verhandelingen 173:1–39), 190 km (airline) N from Cuicatlán, Oaxaca (Mendoza-Quijano and Rendón-Rojas 1994, Herpetol. Rev. 25:34), and 220 km (airline) west from Playa Mocambo, Veracruz (Mendoza-Quijano et al. 1993, Herpetol. Rev. 24:110). These records suggest a continous distribution of this leptothyphlopid from coast to coast between the parallels 19°10'N and 17°26'N, involving the states of Guerrero, Morelos, Puebla, Oaxaca, and Veracruz. We believe this distribution might have been facilitated through accidental human transportation.



Submitted by **HECTOR ELIOSA LEON, LUIS CANSECO MARQUEZ**, and **GONZALO YANEZ GOMEZ**, Laboratorio do Herpetología, Escuela de Biología, Universidad Autónoma de Puebla, 4 sur 104, CP. 72000, Puebla, Estado de Puebla, México.

THAMNOPHIS ORDINOIDES (Northwestern Garter Snake). USA: WASHINGTON: Kittitas Co: between Cle Elum and South Cle Elum along Yakima River, SE 1/4 Sec. 27, T20N, R15E. 21 April 1994. D. M. Darda and W. P. Leonard. Verified by Murray L. Johnson. Central Washington University Museum, Ellensburg (CWU 279). Extends range ca. 24 km E of the only other county record (Nussbaum et. al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press. 332 pp.). Sympatric at this locality with *Thamnophis elegans vagrans* and *T. sirtalis fitchi*. The few records for this taxon from E of Cascade Mountains in Washington and Oregon suggest that emigration from W limited to the immediate vicinity of relatively low mountain passes and along Columbia River Gorge.

Submitted by **WILLIAM P. LEONARD**, Washington Natural Heritage Program, Department of Natural Resources, P.O. Box 47016, Olympia, Washington 98504-7016, USA, and **DAVID M. DARDA**, Department of Biological Sciences, Central Washington University, Ellensburg, Washington 98926, USA.

THAMNOPHIS SAURITUS (Eastern Ribbon Snake). KENTUCKY: Caldwell Co: W edge Dawson Springs off Rt. 62 on W bank of Tradewater River. 24 July 1994. T. W. Taggart, K. J. Irwin, S. L. Collins and J. T. Collins. Verified by Kelly J. Irwin. KU 222229 (juvenile). New county record (Meade 1991, J. Tennessee Acad. Sci. 66:175–182). Specimen taken under 1994 Kentucky Scientific Collecting Permit issued to author.

Submitted by **JOSEPH T. COLLINS**, Natural History Museum, University of Kansas, Lawrence, Kansas 66045, USA.

Dipsosaurus dorsalis (Desert Iguana). USA: Arizona: Pima Co. Illustration by Chuck Smith.

BOOK REVIEWS

Liste des reptiles actuels du monde. I. Chelonii, by Patrick David. 1994. Dumerilia (Publication de l'Association des Amis du Laboratoire des Reptiles et Amphibiens du Muséum national d'Histoire naturelle de Paris) 1:7–127.

Before reviewing the article of interest, an introduction is in order for *Dumerilia* (named in honor of André-Marie-Constant Duméril), a new herpetological journal published by the Laboratory of Reptiles and Amphibians at the Paris Museum of Natural History (AALRAM). *Dumerilia* joins the ranks of other relatively new herpetological journals including *Chelonian Conservation and Biology*, *Herpetological Conservation*, the *Russian Journal of Herpetology*, *Herpetological Natural History* and others. The introduction of so many journals is undoubtedly a reflection of renewed interest in the field of herpetology and the increased need for both specialized journals and more outlets for publication of a burgeoning literature. The scope of *Dumerilia* is broad given the editors' intent to publish "the results of original researches dealing with all aspects of the study of Amphibia and Reptilia, from biology to zoogeography, including systematics, evolution, conservation, or even pure nomenclatural problems." For the time being, only papers submitted by the staff of AALRAM, or colleagues using the collections will be considered for publication.

Dumerilia has an unusual, perhaps unique, review policy. Comments from reviewers are divided into two categories: objective, those dealing with factual errors of omission or commission; and subjective, those based on differences of opinion between the reviewers and the author(s). Objective criticisms must be addressed before acceptance of the manuscript for publication. Subjective criticisms are published in an appendix following the article with the names of consenting reviewer(s). This provides a "point-counterpoint" perspective with the publication of each article. Given the controversy of the traditional anonymous peer review process employed by scientific journals (Pisani 1994; Wilson and McCranie 1993), the policy of *Dumerilia* is an interesting departure from the norm.

The work of Patrick David (1994. Liste de reptiles actuels du monde I. Chelonii) is the first part of an anticipated series in *Dumerilia* listing all presently valid taxa of living reptiles down to the level of subspecies. Scientific names are followed by common names in both French and English as well as pertinent references for each taxon. Six-hundred and ninety-two citations are given making the article a useful reference on the taxonomy and systematics of turtles. Extinct taxa are not listed, even if the extinction was recent. The cut-off date for references was June 15, 1993. David recognizes 273 species in his compilation, the highest number yet reported in comparable modern checklists (Table 1). The inflated number represents not only the recent flux in systematics and taxonomy of turtles but also the various perspectives of the authors and their rules of compilation. For example, differences in the number of families are largely attributable to disagreement over whether the Emydinae and the Batagurinae are subfamilies or families (Gaffney and Meylan 1988). However, King and Burke (1989) recognize batagurines and emydines as subfamilies of the Emydidae, but separate the Staurotypidae from the Kinosternidae following Bickham and Carr (1983).

There are many previous compilations of the world's turtles including books by Pritchard (1979), Obst (1988), and Ernst and Barbour (1989). Beyond the books, with their color photographs and detailed text, are several other modern publications that are best described as annotated checklists of turtle species including Wermuth and Mertens (1977), King and Burke (1989), and Iverson (1992). By now the list of Wermuth and Mertens (1977) is rather dated from the standpoint of turtle systematics and taxonomy, but it is still a useful reference for partial synonymies. That leaves the checklists of King and Burke (1989) and Iverson (1992) as the main competitors with David (1994). So what sets the work of David apart from the previous compilations of the worldUs turtles? In an effort to answer that question, I compared the lists using a variety of attributes (Table 1). Aside from a more recent compilation of the literature, the work of David has common names in both English and French. Other than that it has little more to offer than previous lists. The most useful list, in my opinion, is Iverson (1992) since it has almost everything that all the other lists have. Iverson also provides distribution maps and phylogenies, and I have found the former to be very useful. If you can only afford one checklist of turtles, buy Iverson's. If you need more, David's list would be a useful addition to your library.

A Veterinary Guide to the Parasites of Reptiles, Volume 1 Protozoa, by Susan M. Barnard and Steve J. Upton. 1994. Krieger Publishing Company, Malabar, Florida.154 pp. Hardcover. US $26.50. ISBN 0-89464-832-2.

This book, the first in a series on parasites in reptiles, is directed toward individuals with a prior knowledge of these parasites. Fifty-six figures are provided, but of this number, only thirteen are micrographs. For the flagellates, only *Giardia* is represented photographically; for the amoebas, only *Entameba*. The *Apicomplexa* are better served with micrographs of a *Haemogregarina*, *Caryospora*, *Cryptosporidium*, two of *Eimeria*, and one of *Pythonella* and *Sarcocystis*. Ciliophora are represented by *Balantidium* and *Nyctotherus*. Line diagrams are included for some other genera. In general, the micrographs, diagrams, and descriptions would not be adequate for identification of the protistan parasites if one were not familiar with them.

The parasites are grouped phylogenetically rather than by site of infection which might have been a more functional means. Summaries of phylum level features are given but in some instances would not be of diagnostic value to someone with a light microscope (e.g., apical complex structures, evident with an electron microscope). Subphylum and ordinal characters are given as are those of representative species from reptiles. For each species, a description of major features is given and for most, a line diagram is provided. The identity of the hosts, the location in the hosts, and the nature of the life cycle (direct, indirect, etc.), are recorded. The mode of transmission is provided, as are a brief statement of symptoms and the method of diagnosis and treatment. Unfortunately, quite often the treatment is "none required" or, worse, "none reported." Occasionally, advice is given on how to avoid the parasites (as for *Leptomonas*). The approach in some cases is a bit oversimplified and even odd. For example, *Kinetoplastida* from intestines of reptiles are relegated to the genus *Leptomonas* when in fact some are *Herpetomonas* (Dollahon and Janovy 1971). Of course this has little bearing on treatment. Also, why did the authors include *Tritrichomonas muris* from a rodent in their line drawings?

Coverage of Microspora and Myxozoa is very sparse (1–2 paragraphs each) both concluding with no treatment in reptiles being recorded. Coverage is provided for Sarcomastigophora (flagellates and amoebas), and Apicomplexa, as well as a chapter on organisms of uncertain nature. Oddly, there are no micrographs or diagrams of the lizard malarias, only life cycles.

In addition, there is a chapter on laboratory procedures and how to do microscopy. Xylene on lenses is not a good idea, however. Procedures for collecting, preserving, and examining fecal samples are provided. Staining procedures are given for intestinal protozoans and procedures for preparing blood smears (no procedures are given for stains except the name in this case) and tissue impressions.

Appendix I is a list of parasiticides used in treatment of protozoan infection. Given are the organism, the therapeutic approach, the dosage used in mg/kg, a reference mode of administration and comments. Appendix II supplies information on where to acquire chemicals, etc. Appendix III is a summary of hosts/parasites mentioned in the text.

There is a glossary of terms to provide definitions of terms in the text, such as enanation, a state of starvation. A reference section follows.

If you have not had training in recognizing parasitic protists this book will not provide an effective mechanism for so doing. Additional micrographs would be helpful along with an organization based on site of infection rather than taxonomy.

PUBLICATIONS RECEIVED

Manual y Claves Ilustradas de los Anfibios y Reptiles de la Región de Chamela, Jalisco, México, by Aurelio Ramírez-Bautista. 1994. Instituto de Biología, Universidade Nacional Autónoma de México. Cuadernos del Instituto de Biología 23. 127 pp., 78 photographs (74 in color on 16 plates). Softcover. In Spanish. ISBN 968-36-3897-X. US $25.00 plus $4.00 for air-mail shipment and handling. Available from Instituto de Biología, UNAM Cordinacion de Bibliotecas, A.P. 70-233, 04510 México, D.F. Tel. 622-56-89, or from the author: Aurelio Ramírez-Bautista, Instituto de Biología, Departamento de Zoología, A.P. 70-153, 04510 México, D.F.

This handbook describes the herpetofauna of the Chamela Biological Station, a 1600-ha preserve in the southwestern portion of the state of Jalisco, México. This area receives moderate but strongly seasonal rainfall (>700 mm annual average) and is characterized by tropical deciduous forest. The region harbors 19 amphibians and 63 reptiles (including five species of marine turtles and one sea snake). Spanish common names are provided for many species. Individual species accounts provide descriptions (morphology, coloration, etc.) and briefly summarize information concerning habitats, habits, and general distribution.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Techniques, Natural History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles or Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Natural History Notes or Geographic Distribution manuscripts; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, New Jersey Field Office, The Nature Conservancy, 200 Pottersville Road, Chester, New Jersey 07930, USA (tel. 908-879-7262).

Herpetological Review is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Karen Toepfer, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 600		$300
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 600	$150

For back orders only: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA (fax 314-977-3658).

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1995 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $25; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $30 for one year. All members receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $17. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $15; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Karen L. Toepfer, SSAR Treasurer, P.O. Box 626, Hays, Kansas 67601–0626, USA. Telephone: (913) 623-4258; Fax: (913) 625-8890; e-mail: aren@ksuvm.ksu.edu or aren@ksuvm.bitnet.

HERPETOLOGICAL REVIEW (ISSN: 0018-084X) is published quarterly in March, June, September and December by the Society for the Study of Amphibians and Reptiles at 303 West 39th St., Hays, KS 67601-1518. Application to mail at 2nd Class Postage rates is pending at Hays, Kansas with additional entry offices. **POSTMASTER:** Send address changes to *HERPETOLOGICAL REVIEW*, P.O. Box 626, Hays, KS 67601-0626.

Future Annual Meetings

1995 — Appalachian State University, Boone, North Carolina, USA, 8–13 August (R. Wayne Van Devender, Chair).
1996 — University of Kansas, Lawrence, Kansas, USA, 24–29 July (William E. Duellman, Chair).
1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July.

SSAR BUSINESS

Index to Catalogue of American Amphibians and Reptiles

A complete index of all published accounts of the *Catalogue* (up to 1994) is now available in two parts:

Index to Accounts 1 – 400 (64 pages) $5.00

Index to Accounts 401 – 600 (32 pages) $5.00

Shipping and handling charge $1.00 for each. Make checks payable to "SSAR."

Send orders to: *Robert D. Aldridge, Department of Biology, 3507 Laclede, Saint Louis University, St. Louis, Missouri 63103, USA. Fax (314) 977-3117.*

SSAR Translations Project

This project was initiated to make available to SSAR members accurate translations of foreign language research articles. Since SSAR does not budget money for the translation of articles, we must rely on contributions from members. If you have an article that has been translated, please send a copy of the translation and original (if available) to the translations editor. At present we have a few people who have offered their expertise in translating submitted articles and we are always interested in hearing from any others who might be interested in helping as needed.

Currently, we have in excess of 200 articles available through the Translations Project. In addition, we have, in previous issues, listed articles available from the National Translations Center (NTC) and the National Museum of Natural History (SHIS). For articles from NTC write to: *John Crerar Library, 35 West 33rd Street, Chicago, Illinois 60616, USA.* For articles from SHIS write to: *SHIS Division of Reptiles and Amphibians, National Museum of Natural History, Washington, D.C. 20560, USA.*

For copies of SSAR translations send your requests to: *R. W. Krohmer, Translations Project Editor, Science Department, Saint Xavier University, 3700 West 103rd Street, Chicago, Illinois 60655, USA.*

Please include $1.00 for postage plus 10 cents per page to cover copying costs (the number of pages of the original and translation are in parentheses). Please make check or money order (in U.S. currency) payable to "R. W. Krohmer, Editor; SSAR Translations Project."

Previous titles have appeared in *Herpetological Review* 10(3):82–83, 1979; 13(4):111–112, 1982; 16(1):2–3, 1985; 17(2):33–34, 1986; and 22(2):35–37, 1991. New titles will be published in *Herpetological Review* as they become available.

New Submissions 1994

BEHRMANN, H-J. 1981. Care and reproduction of *Varanus t. timorensis* (Reptilia: Sauria: Varanidae). Salamandra. 17(3/4):198–201. translation (2 pages), original (2 pages).

Erection of the penes, 7. Embryonic development, 8. Phylogenetic considerations on the penes, 9. Summary. translation (19 pages), no original available.

BOUR, R. 1978. The living turtles of Masagascar (Malagasy Republic): A systematic list and description of two new subspecies (Reptilia: Testudines). Bull. Soc. Et. sci. Anjouan, nouvelles serie. 10:141–154. translation (11 pages), original (8 pages).

GASC, J. P. 1970. The different patterns of innervation of the iliocostalis muscle in snakes. Bulletin du Association des Anatomistes, 5th Congress (Sofia). 145:168–175. translation (3 pages), original (4 pages).

GUIBE. J. 1949. Revision of the genus *Langaha* (Ophidia): Sexual dimorphism and its taxonomic consequences. Memoires de l'Institut Scientifique de Madagascar, Serie A. 3(2):147–155. translation (5 pages), original (8 pages).

About our Cover

Dendrobates azureus, the blue poison frog, was described by Marinus D. Hoogmoed in 1969 (Zool. Meded., Leiden 44:134). It is known only from the vicinity of the type locality, on the western slope of Vier Gebroeders Mountain, Surinam.

The family Dendrobatidae contains about 168 species allocated to eight genera (*Aromobates*, 1 sp.; *Colostethus*, 87 spp.; *Dendrobates*, 26 spp.; *Epipedobates*, 26 spp.; *Mannophryne*, 8 spp.; *Minyobates*, 9 spp.; *Nephelobates*, 6 spp.; and *Phyllobates*, 5 spp.), whose collective distribution is from Nicaragua to the Amazon Basin of Bolivia and to the Guianas and southeastern Brazil (Frost, D. R. 1995. Dendrobatidae. *In* Amphibian Species of the World. Version 2/95. Electronic manuscript maintained under the auspices of The Herpetologists' League).

The "arrow-poison" or "dart-poison" frogs have long attracted the interest of both the scientific and herpetocultural communities owing to their often-brilliant coloration, the highly toxic skin secretions of some species, and their diversity. Jerry G. Walls' recent popular book (*Jewels of the Rainforest: Poison Frogs of the Family Dendrobatidae*, TFH Publications, Neptune, New Jersey. 288 pp.) mirrors this interest.The most recent taxonomic treatments are those by Myers (1987. Pap. Avul. Zool., São Paulo 36:301–306), Myers et al. (1991. Am. Mus. Novit. 3002:1–33), and La Marca (1992. Cat. Taxon. Biogeog. Bibliog. Ranas Venezuela, Cuad. Geograf., Univ. Los Andes, No. 9; 1994. Publ. Assoc. Amigos Doñana, No. 4, 75 pp.; and 1994. An. Invest. 1991, Univ. Los Andes: 39–41). However, as is the case with many groups of tropical amphibians, new species continue to be discovered and taxonomic arrangements are dynamic, particularly with respect to assignments of species to genera.

Recent research by John W. Daly and colleagues has provided evidence for dietary uptake of skin toxins. Also confirmed is the relationship between consumption of particular groups of forest-floor arthropods and production of specific classes of toxic alkaloids. [See Current Research, p. 68 this issue, for details.] This work helps explain the observations of zoo personnel and herpetoculturists that dendrobatid frogs maintained in captivity for long periods tend to lose their toxicity.

The cover photo was taken by herpetologist **David G. Barker**, a Texan with broad interests in herpetology and herpetoculture. He is co-author (with Tracy J. Barker) of *Pythons of the World, Volume I, Australia*, which features many of his photographs. He took this photo at the National Aquarium in Baltimore, using a Pentax LX camera, Vivitar 90mm f2.5 lens, and Kodachrome 64 film, at 1/75th sec. at f22. Separation and imaging by **Jim Bridges**, Herpeto Inc., Hollywood, Florida, USA.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
1995 ANNUAL MEETING

Dates: 8–13 August 1995
Place: Appalachian State University, Boone, North Carolina, USA

Keynote Address: "TERRITORIAL BEHAVIOR: TESTING THE ASSUMPTIONS," by Judy Stamps (University of California, Davis).

Symposium: "EASTERN RATTLESNAKES: BIOLOGY AND CONSERVATION OF *CROTALUS HORRIDUS* AND *CROTALUS ADAMANTEUS*." *Organizers*: William S. Brown (Skidmore College, Saratoga Springs, New York, USA) and Walt Timmerman (Helena, Montana, USA). *Participants for session on Timber Ratilesnake*: W. S. Brown, B. W. Bowen, A. -M.Clark, L. M. Bushar, H. K. Reinert, D. E. Keyler, B. L. Oldfield, R. Stechert, A. Breisch, S. H. Harwig, S. Smith, W. H. Martin, E. Possardt, T. Tyning, R. T. Zappalorti, D. Wynn, A. H. Savitzky, B. A. Savitzky, G. Rocco, J. B. Sealy, A. Soha, J. T. Taylor, A. C. Smith, Jr., K. Michell, R. R. Rupert, Jr., D. F. Fraser, J. Congdon. *Participants for session on Eastern Diamondback Rattlesnake*: W. Timmerman, W. Auffenberg, W. H. Martin, D. B. Means, G. Dalrymple, P. Kain, S. Telford, J. W. Gibbons, R. Mount, L. Jones.

Symposium: "EVOLUTIONARY PATTERNS OF AMPHIBIAN DEVELOPMENT." *Organizer:* Stephen M. Deban (University of California, Berkeley, USA). *Participants*: S. M. Deban, J. C. O'Reilly, S. B. Marks, C. S. Rose, D. Meinhardt.

Regional Societies Conference: "REGIONAL HERPETOLOGICAL SOCIETIES: PROGRAMS AND PROJECTS." *Organizer*: Martin J. Rosenberg. See page 64 of this issue for details.

Workshop: "HERP PHOTOGRAPHY." *Organizers*: David Dennis and J. Eric Juterbock.

President's Travelogue Slide Shows: Profusely-illustrated lectures of exotic herps and habitats. "Amphibians and Reptiles of the Lowland Maya Area," by Julian C. Lee; "The Herpetofauna of the Southern African Arid Zone," by Aaron M. Bauer; and "Amphibians and Reptiles of Australia: After the World Congress," by R. Wayne Van Devender.

Multimedia Presentations: "Herps of the West" and "Amphibians of the Appalachians" by David Dennis and J. Eric Juterbock; "Herpetological Namesakes" by Kraig Adler, David Dennis, and J. Eric Juterbock.

Oral and Poster Sessions: Several concurrent sessions each day.

Student Paper Awards: Seibert Prizes to be awarded to the two best student-presented papers at the meeting ($250 first prize, $150 second prize).

Student Travel Grants: Ten awards of $200 each will be given. For details see March 1995 issue (page 1).

"The Great Reprint Scavenge" (for students only!). Professionals are asked to clear unwanted duplicate reprints out of their offices (and receive free raffle tickets as a "thank you").

Social Activities: Welcoming Social, the SSAR Annual Auction, Barbecue Dinner, Graduate Student Social, local tours.

Field Trips: Grandfather Mountain, Linville Gorge Wilderness Area, night trips for salamander watching, and others.

Live Exhibit: Featuring herps of the region. Sponsored by the North Carolina Herpetological Society and Appalachian State University. Animals available for viewing and photography.

Costs and Accommodations: Registration $75 student, $110 regular; $50 spouse. After 15 April 1995, registration fees will be $115, $145, and $50, respectively. Lodging at Broyhill Inn (meeting location) will be $40 (single occupancy) or $46 (double occupancy) per day. Dormitory room rates are $15 (single) or $10 (double) per day plus $8 for linen. Approximately 100 additional rooms are reserved at several local motels for $49–$70 per day. Note that Boone, North Carolina is a popular summer resort area; reservations should be made well in advance.

Further Details: See December 1994 issue of *Herpetological Review* (pages 133–135). Meeting Announcement/Call for Papers was mailed to all North American members of SSAR in January 1995; it is also available on request from *Dr. Robert Wayne Van Devender, Department of Biology, Appalachian State University, Boone, North Carolina 28608, USA (telephone 704-262-2665; fax 704-262-2127; e-mail vandevenderr@appstate.edu).* Address questions about meeting sites, rooms, registration, etc., to *Richard Hudson, Office of Conferences and Institutes, University Hall (telephone 704-262-3045; fax 704-262-4992; e-mail hudsonre@appstate.edu).*

NEWSNOTES

Announcing *AmphibianDecline*

AmphibianDecline is an Internet forum established to facilitate the exchange of information on the biology and conservation of declining amphibians. Topics of discussion might include information on the status of particular species or populations as well as research findings on how disease, UV radiation, population genetics, acid precipitation, pesticides, non-native species, etc., are affecting amphibian populations. discussions about potential causes of decline and techniques for conducting surveys or measuring relevant factors are also encouraged.

Subscribers to the forum will receive all E-mail sent to *AmphibianDecline* and may also send messages which will automatically be distributed to other *AmphibianDecline* subscribers.

If you have E-mail access to the Internet, you can subscribe to *AmphibianDecline*. To subscribe, send a message to listproc@ucdavis.edu. The subject should be Subscribe and the message needs to be:

Subscribe AmphibianDecline Firstname Lastname

Use your own first and last name. Do not include anything else in the message. You will receive confirmation that your subscription has been received as well as information on how to send messages to *AmphibianDecline* and how to end a subscription. For additional information or comments, contact: *Gary M. Fellers, Research Biologist, National Biological Survey, Point Reyes National Seashore, Point Reyes, California 94956, USA. Tel. 415-663-8522; e-mail: gmfellers@ucdavis.edu.*

ISSCA Announces Reduced Student Rate

The International Society for the Study and Conservation of Amphibians (ISSCA) was founded in 1988 in Paris, France. The aims of ISSCA are to contribute (1) to the study and knowledge of amphibians (batrachology), (2) to the conservation of amphibians and to that of their environment, (3) to the establishment, reinforcement, and facilitation of bonds between batrachologists, and (4) to the promotion of batrachology as an independent scientific discipline.

Four times a year, ISSCA publishes the journal *Alytes*, which features original, peer-reviewed papers in English, French, or Spanish in any discipline dealing with amphibians. A "Guide for Authors" can be obtained from either of the addresses listed below or from a recent issue of the Journal.

The regular rate for a 1995 subscription to *Alytes* and membership in ISSCA (which includes a news bulletin, *Circalytes*) is $54.00 for individuals and $108.00 for institutions. Beginning this year, students may subscribe to *Alytes* and hold membership in ISSCA for half price ($27.00). Payment may be sent in U.S. dollars (make check payable to "ISSCA") to Mark L. Wygoda, ISSCA Deputy Treasurer, P.O. Box 92000, McNeese State University, Lake Charles, Louisiana 70609, USA. Payment in French francs (270 FF regular rate; 135 FF student rate; 540 FF institutional rate) may be sent to ISSCA, Laboratoire des Reptiles et Amphibiens, Museum national d'Histoire naturelle, 25 rue Cuvier, 75005, Paris, France.

Herpetology Combined Museum Collections Database

The Department of Herpetology, California Academy of Sciences is host to the *Herpetology Combined Museum Collections Database*. At present, the entire herpetological holdings of the following institutions are on-line and accessible: California Academy of Sciences (CAS), Carnegie Museum (CM), Louisiana State University (LSUMZ), Texas Natural History Collection (THNC), University of California, Berkeley (MVZ), University of Texas, Arlington (UTA), Smithsonian (USNM), and the Peabody Museum, Yale (YPM). In addition, the database includes the Caudata and Gymnophiona holdings of Harvard University (MCZ).

Data are limited to numbers of specimens held in each institution by genus and/or species; i.e., who has what and how many. The HCMC Database is accessible by (1) searching gopherspace via Veronica using the keyword "herpetology," (2) by accessing the CAS gopher directly: %gopher gopher.calacademy.org; or (3) via World Wide Web: http://www.calacademy.org.

Institutions wishing to add their data to the HCMCD should contact: *Jens Vindum, California Academy of Sciences; e-mail: jvindum@calacademy.org or José Rosado, Museum of Comparative Zoology; e-mail: jrosado@mcz.harvard.edu.*

Submitted by: *Robert C. Drewes, Curator & Chairman, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA. e-mail: casherp@mercury.sfsu.edu.*

Texas Natural History Collections Databases

The Texas Natural History collections (TNHC), a division of Texas Memorial Museum of the University of Texas at Austin, is pleased to announce availability of collections databases and collections-related files:

http:/www.utexas.edu/depts/tnhc/.www
gopher://gopher.utexas.edu:3003/11/pub/tnhc
(or follow gopher menus: Texas; University of Texas Austin; Colleges and Departments; College of Natural Sciences; Texas Natural History Collections)

WAIS-indexed databases from the ichthyology and herpetology collections are searchable. We are also pleased to provide related collaborative projects through the same location. The Business Office of the American Society of Ichthyologists and Herpetologists (ASIH), now based at TNHC, provides (WWW & Gopher) an updated membership directory, meeting announcements, and general information about the society. Finally, the University of Texas Biodiversity Resources and Collections (UT-BRAC) collaborative project (WWW & Gopher) provides links to other natural history and biodiversity resources at UT Austin.

Please contact us should you experience any difficulties accessing these files, or with your comments and questions. *Dean A. Hendrickson, Curator of Ichthyology (e-mail: deanhend@mail.utexas.edu; tel. 512-471-9774; fax 512-471-9775); David C. Cannatella, Curator of Herpetology (e-mail: catfish@mail.utexas.edu); or Carol K. Malcolm, Collections Manager for Ichthyology and Herpetology (e-mail: cmalcolm@utxvms.cc.utexas.edu).*

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due on 15 October 1995, with notification by 1 December 1995. Grantees are expected to complete their Academy visit by 15 September 1996. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

Call for Student Proposals

The J. Larry Landers Student Research Award is presented annually to the best student research project concerning the biology of the gopher tortoise, *Gopherus polyphemus*, or any aspects of its sandhill community. This would include vegetation management practices and burrow commensals. Recent awards have averaged $400. Students interested in applying should submit a concise description of their project with a detailed budget (no more than four pages, double spaced) and a brief curriculum vita to *Bob Herrington, Research Advisory Committee, Department of Biology, Georgia Southwestern College, Americus, Georgia 31709, USA.* Deadline for receipt of proposal to be considered for the 1995 award is 31 August 1995.

Murphy Retires from Dallas Zoo

James B. Murphy, Curator of the Department of Herpetology at the Dallas Zoo, will retire as of 1 June 1995. His new address after this date will be: *National Zoo, c/o Herpetology Department, 3000 Connecticut Avenue, N.W., Washington, D.C. 20008, USA.*

Dallas Zoo Rattlesnakes Available

The Dallas Zoo is willing to donate a laboratory colony of amelanistic western diamondback rattlesnakes (*Crotalus atrox*) with anomalous variable scalation to a researcher interested in continuing a study of phenotypic variation of scutellation in this taxon. Two publications have resulted from data obtained from this group of snakes which includes virtually "scaleless" individuals (Murphy et al. 1987, Herpetologica 43:292–300; McCrady et al. 1994, Zoo Biology 13:95–106). Send proposal to: *Fred LaRue, Deputy Director of Animal Operations, Dallas Zoo, 621 East Clarendon Drive, Dallas, Texas 75203, USA.*

Amphibians and Pest Control

With the current interest in diversification in farming, and a progressive move to more environmentally-friendly organic farming systems, the Ministry of Agriculture in Britain has commissioned a review of the current state of knowledge on the role that amphibians play in the control of invertebrate pest species, with particular reference to organic farm systems. I am currently working on this project along with Pim Arntzen at the University of Bangor, Wales, United Kingdom.

Although popular accounts exist of examples of amphibians as biological control agents, many of these are out of date and probably do not reflect the current state of affairs. We are interested in getting a range of views on the following issues:

1. Incidences where a decline in amphibian numbers has resulted in pest/insect outbreaks and/or an increase in pesticide use.
2. Any examples of organic agriculture in which amphibians have been especially encouraged for their function in pest control.
3. Evidence of the persistence of amphibian populations in association with farm ponds, ditches, etc., or agricultural environments in general.
4. Any other thoughts on the role amphibians may play as controllers of invertebrate numbers.

To be incorporated in the present survey, information must be received by 15 July 1995. Please reply to John Wilkinson c/o Pim Arntzen on BSS181@Bangor.ac.uk, or in writing to: *John W. Wilkinson, School of Biological Sciences, Brambell Building, University of Bangor, Gwynedd LL57 2UW, United Kingdom.*

Bullfrog Harvest Information Needed

The Ontario Ministry of Natural Resources is currently trying to build a case to end the commercial and recreational harvesting of American bullfrogs (*Rana catesbeiana*) in the province. Consequently, information is needed to support this change. Study results from the northeastern U.S. or midwestern states would be especially useful. Any recent information that you can provide that relates to bullfrog conservation, management, or population declines would be very helpful. Please send information to: *Kevin Lamacraft, Information Officer, Brockville Area Office, P.O. Box 605, 10 Oxford Avenue, Brockville, Ontario, Canada, K6V 5Y8. Tel. (613) 498-9625 or e-mail: SOrchard@RBML01.RBCM.GOV.BC.CA.*

DAPTF Bullfrog Introduction Questionnaire

Investigations into amphibian declines sometimes indicate that introduced species are involved. Many amphibian workers are concerned that bullfrog introductions are responsible for severe damage to native faunas, especially other amphibian species. Although bullfrogs have already been introduced to many countries, and hence much damage may already have been done, new ranching operations or introductions are still being considered in areas outside this species' natural range. New bullfrog farming ventures are still initiated because of the appeal of financial return for a small investment. However, we know of no such operation which has been commercially successful.

Mike Lannoo, the Declining Amphibian Populations Task Force (DAPTF) Coordinator for the U.S., has recently been invited to join the Invasive Species Specialist Group of the Species Survival Commission, as an advisor on amphibian matters. The DAPTF has alerted this Specialist Group to the problems posed by bullfrogs becoming established outside of the natural range, with the result that the ISSG has proposed aiming recommendations at governmental levels. In order to provide a sound basis for these recommendations the DAPTF wishes to collate information on bullfrog introductions to establish the true magnitude of the problem. We need and welcome your contributions. We would like to know:

1. Sites/countries of bullfrog introductions (if possible distinguishing between direct introductions, escapes from farms/ranches, and incidental introductions via fish stocking).
2. Information on the impacts on native fauna.
3. Information on known eradication measures—successes or failures.
4. Whether any known bullfrog farms/ranches have been economically viable.
5. Any other comments that may be of importance.

In order to draw up firm conclusions, we would be grateful if literature could be cited in your response. Alternatively, if you can pass on personal observations, then a note of your professional status (e.g., wildlife manager, professional ecologist, etc.) would add weight to any conclusions drawn. In addition, please supply your address and phone number for any necessary follow-up inquiries. Please send information to: *Michael Lannoo, Muncie Center for Medical Education, Rm. 209 Maria Bingham, Ball State University, Muncie, Indiana 47306-0230, USA; e-mail: 00mjlannoo@bsuvc.bsu.edu.*

Addendum to Wilfred T. Neill Bibliography

In 1993 we published a biographical sketch and bibliography of Wilfred T. Neill (Liner et al. 1993. Smithsonian Herp. Infor. Serv. 95:1–24). At that time we felt reasonably sure that all publications of this prolific author were covered but this was not the case. Recently, a publication that we overlooked was brought to our attention by C. Kenneth Dodd, Jr., to whom we are grateful. The citation is: Neill, W. T. 1964. Road log, pp. 7–10 *In:* W. Auffenberg, W. T. Neill, T. H. Patton, and S. D. Webb. Guidebook 1964 Field Trip in Central Florida. Soc. Vert. Paleo. Ann. Meeting. Sponsored by the University of Florida and the Florida Geological Survey, Gainesville, Florida. 15 November 1964. 52 pp.

Ernest A. Liner, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA, and *David L. Auth, Department of Herpetology, Florida Museum of Natural History, Museum Road, University of Florida, Gainesville, Florida 32611-2035, USA.*

Transfer of Sensitive Information

The National Biological Service is formulating a policy on protecting sensitive location data (e.g., breeding sites for endangered amphibians). To develop a policy that suits the needs of all vulnerable taxa will require input from many persons. If you know of a situation where ad lib information transfer could damage a wild population or taxon, send a one paragraph description of the circumstances to: *Dr. David H. Ellis, Endangered Species Research Branch, Patuxent Environmental Science Center, 11510 American Holly Drive, Laurel, Maryland 20708-4019, USA.*

MEETINGS

Meetings Calendar

15-19 June 1995—Annual Meeting of the American Society of Ichthyologists and The Herpetologists' League. University of Alberta, Edmonton, Alberta, Canada. Contact Dr. Joseph S. Nelson, Department of Biological Sciences, University of Alberta, Edmonton, Canada T6G ZE9. Tel. (403) 492-4741. Fax (403) 492-9234.

23–25 June 1995—International Gecko Society Symposium. Palm Mountain Resort, Palm Springs, California. Contact IGS Symposium, P.O. Box 370423, San Diego, California 92137-0423, USA.

6–10 July 1995—International Congress of Chelonian Conservation. Tortoise Village, Gonfaron, France. Contact: Secretariat, SOPTOM, B.p. 24, 83590 Gonfaron, France. Tel. (33) 94 78 26 41. Fax (33) 94 78 24 27.

8–13 August 1995—Annual Meeting of the Society for the Study of Amphibians and Reptiles. Appalachian State University, Boone, North Carolina, USA. *Refer to meeting announcement on page 58 of this issue for contact numbers and detailed information.*

25–30 August 1995—2nd International Asian Herpetological Meeting. Ashgabat, Turkmenistan. Contact: Theodore J. Papenfuss, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA. *Refer to meeting announcement below.*

26–29 October 1995—2nd Annual Conference of the Association of Reptile and Amphibian Veterinarians (ARAV), Sacramento, California, USA. *Refer to meeting announcement below for further details.*

Mid-April 1996—2nd International Conference on the Biology and Conservation of the South Asian Amphibians and Reptiles, University of Peradeniya, Sri Lanka. Deadline for receipt of abstracts 30 August 1995. Contact: Anslem de Silva, Conference Director, Faculty of Medicine, University of Peradeniya, Sri Lanka. Tel. 94-08-88130. Fax 94-08-32572.

Second International Asian Herpetological Meeting

The Asiatic Herpetological Research Society, Institute of Zoology, Academy of Sciences of Turkmenistan, and Nikolsky's Herpetological Society under the Russian Academy of Sciences will hold the Second International Asian Herpetological Meeting in Ashgabat, Turkmenistan from 6 to 10 September 1995.

Ashgabat is the captial of Turkmenistan. It is situated between the foothills of the Kopet-Dagh Mountains and the Kara-Kum desert. This area is of great herpetological interest. About 80 species of amphibians and reptiles including the Desert Monitor (*Varanus griseus*) and Central Asian Cobra (*Naja oxiana*) occur in the vicinity of Ashgabat. Excursions will be arranged to visit natural habitats and cultural sites in this country.

Persons interested in attending the meeting should contact any of the following individuals to register or to obtain additional information:

Dr. Sc. Sakhat M. Shammakov, Institute of Zoology, Academy of Sciences of Turkmenistan, 744000 Ashgabat, Azady Street 59, Turkmenistan. Tel. (363-2) 25-37-91; fax (363-2) 25-37-91 or (363-2) 29-04-92.

Dr. Theodore J. Papenfuss, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA. Tel. (510) 642-3567; fax (510) 643-8238; e-mail: asiaherp@uclink2.berkeley.edu.

Dr. Sc. Natalia B. Ananjeva, Department of Herpetology, Zoological Institute, Russian Academy of Sciences, 199034 St. Petersburg, Russia. Tel. (812) 218-07-11 or 218-03-11; fax (812) 219-29-41; e-mail: anb@zisp.spb.su.

2nd Annual ARAV Conference

The Association of Reptile and Amphibian Veterinarians (ARAV) will hold its second annual conference 26–29 October 1995 at the Radisson Hotel in Sacramento, California. Herpetoculturists, professional herpetologists, veterinarians, and students are invited to attend. Workshops on basic and advanced herptile medicine and surgery, as well as presentations on herp husbandry, reproduction, conservation, medicine, surgery, and research will be included in the three day event.

For conference registration or ARAV membership information contact: *Wilbur Amand, VMD, P.O. Box 605, 1 Smithbridge Road, Chester Heights, Pennsylvania 19017, USA. Fax (215) 387-2165.*

III Congreso Latinoamericano de Ecología

The 3rd Latin American Congress of Ecology will be held at the Universidad de Los Andes, Mérida, Venezuela, from 22–28 October 1995. Deadline for receipt of abstracts is 30 July 1995. Fees are US $100 (regular) and US $70 (students).

For more information, please contact *Dr. Jaime E. Péfaur, Executive Secretary, III CLAE, Fax (58) 74 401286; e-mail CLAE@ula.ve.*

1995 ASC Annual Meeting at UC Berkeley

The 1995 ASC Annual Meeting will be hosted jointly by the University of California, Berkeley and the California Academy of Sciences on 30 June – 2 July. The meeting will feature a workshop on "Natural History Collections on the Information Superhighway." Partnerships among systematics collections of various kinds, and state and federal agencies will be the topic of another session.

Representatives of NSF, the National Biological Service, and EPA have been invited to talk about government partnerships and information superhighway issues. Speakers will address efforts to create a National Biodiversity Information Infrastructure or Center for Biodiversity Information, and the role of systematics databases therein. A representative of Conabio, México's biodiversity center, has also been invited.

For registration and hote information, contact: *ASC, 730 11th Street, NW, Second Floor, Washington, D.C. 20001-4521; Tel. (202) 347-2850; fax (202) 347-0072.*

Herpetological Review Now On-line

A pre-publication listing of the contents of each issue of *HR* is now available from several on-line sources. Postings should occur approximately one month before the publication of the next issue. This service should be helpful to herpetologists in countries where mail delivery is unpredictable, as well as providing pre-publication information to other interested persons. *HR*'s on-line contents listing is available from the following:

Herp-Net — direct dial to 215-464-3562 (300–2400bps 8-N-1) or 215-698-1905 (9600, 14.4kbs) 24 hours per day. Select "Herp. Review" menu item.

Via **Usenet** newsgroup, "sci.bio.herp" (use any newsreader available on your network account), look for the posting "Herpetological Review Contents."

The Herpetology World Wide Web at Harvard, maintained by Michael Eisen, can be accessed at:

http://xtal200.harvard.edu:8000/herp

Then select the menu item "Current Contents of Herp Journals."

Via the **HERP-L** distribution list available to any Internet address. To subscribe send email to listproc@xtal200.harvard.edu with the phrase "subscribe HERP-L <your name>" in the body of the message.

On the commercial **CompuServe** Information Service in their Animal Forum [Go Petstwo] reptile/amphibian library section 6. Search by keyword "SSAR." On **America Online**, under "pet" section, search reptile files.

This service is made possible by Mark Miller and the Herpetology On-Line Network. Miller can be reached by FAX at 215-464-3561 or Internet email: mmiller@tjuvm.tju.edu.

REGIONAL SOCIETIES

Regional Herp Society Conference at SSAR Annual Meeting

The annual SSAR meeting this August will feature a Regional Herpetological Society Conference consisting of eight presentations. The conference, designed to share ideas, programs, and projects relating to regional herpetological societies, is scheduled for Thursday, 10 August, from 0845 to 1500 hours. All individuals attending the SSAR meeting are invited to attend any or all of the papers. The program appears below:

Welcome and Introductions
"Producing a High Quality Regional Herpetological Society Newsletter, with or without a Computer," by J. C. Beane and B. Bartholomew.
"Mid-Ohio Herpetological Society's 'Counselor's Corner,'" by S. Highley.
"Public Involvement in the Protection of Endangered Reptiles in Ontario," by B. Johnson, D. Martin, and B. Porchuk.
"Tax-Exempt Status for Herpetological Societies: Is it Worth the Hassle?" by M. Kikta.
"Contributions Which Non-academic Herpetologists Can Make to the Scientific Study of Declining Amphibian Populations," by S. Moody.
"Regional Herpetological Societies and the Science Olympiad," by G. W. Renwick and M. J. Rosenberg.
"Marketing Herpetology," by J. H. Schoenfelder.
"North Carolina Herpetological Society: Educational and Research Endeavors," by A. Somers.
"Educational Programs of the Long Island Herpetological Society," by P. R. Warny, Jr.
Open Forum: "Regional Herpetological Societies—Where Do We Go from Here?"

A display of regional herpetological society newsletters representing about 75 regional societies will be available for viewing throughout the SSAR meeting. For further information about this conference, contact the Regional Society Liaison (see inside back cover).

NOAH Journal Revived

The *Journal of the Northern Ohio Association of Herpetologists* is a semi-technical publication. Articles are of general interest to the amateur and professional herpetologist and herpetoculturist. Suitable articles for publication in the *Journal* range from original research to notes on captive husbandry or summary manuscripts on a specific topic within herpetology. After a several year leave of absence, the *Journal* is again being published by NOAH. Currently, efforts are being made to produce a semi-annual publication. Titles in the current issue include: "A review of temperature-dependent sex determination in reptiles," by Mark S. Wilson; "Over de soorten zeilhagedissen van het geslact *Hydrosaurus* (About the sail lizard species of the genus *Hydrosaurus*)," by Gerard Visser and Judith van der Koore (translated by Bert Langerwerf); "*Heterodon* and other not-so-harmless 'harmless' snakes," by Mark T. Witwer; "The reptiles of the Dalby District and adjacent parts of the Darling Downs (Queensland)," by Raymond Hoser and John Scanlen.

For more inforamtion on J. NOAH, contact *Gregory J. Watkins-Colwell, Editor, 2323 N. Knoll, Beavercreek, Ohio 45431, USA (e-mail: GJWC@aol.com).* For more information on membership in NOAH, write to: *NOAH, Department of Biology, Case Western Reserve University, Cleveland, Ohio 44106, USA.*

Texas Herpetological Society Grants-in-Herpetology

Amount: Requests should not exceed $500.

Who May Apply: Priority one: Non-professional herpetologists, including non-students, amateurs, public school undergraduates, and college undergraduates. Priority two: Professionals, graduate students, and wildlife biologists.

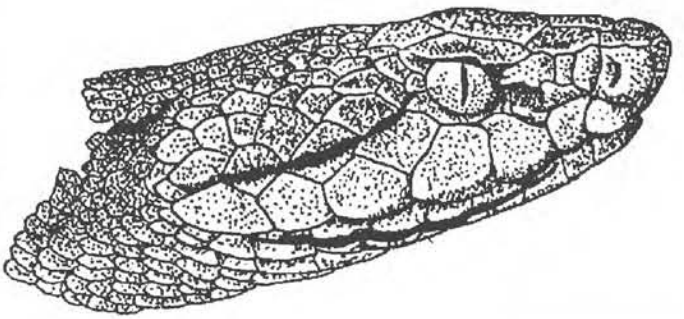
Projects: All research projects dealing with Texas reptiles and amphibians, native or introduced, and dealing with conservation, natural history, distribution, evolution, systematics, ecology, behavior, physiology, or husbandry.

Proposal Format:

1. Typed, double-spaced, on one side of bond paper.

2. Cover page: Should include a) title; b) amount requested; c) project term; d) name and address of principal investigator(s); e) occupation.

3. Body: a) Clearly state the objectives; b) justify based on previous research or a lack thereof; c) define the relationship between the disposition of funds and the expected results; d) define the qualifications of all investigators in the project; and e) include a letter of agreement from each consultant. The body should not exceed 2500 words.



4. Budget: Budget items should be listed and justified. Funds requested can not be used for salaries.

5. Literature Citations: literature citations in the body should be referenced.

Report: In the event an award is made, a report as to the results and deposition of funds must be submitted to the Secretary/Treasurer within six months of the completion date stated in the proposal. A final report is required following the completion of the project.

Entry: An original and four copies of the proposal should be submitted to the Secretary/Treasurer prior to 1 January 1996. The number of awards made will depend on the number of requests and the amounts requested. The awards will be announced on 15 March 1996.

Send proposals to: *David Haynes, Sec./Treas., Texas Herpetological Society, 1810 W. Mulberry, San Antonio, Texas 78201, USA.*

Agkistrodon c. contortrix (Southern Copperhead). USA: South Carolina: Jasper Co. Illustration by Chuck Smith.

OBITUARY

In Remembrance of C. J. McCoy

C. J. (Jack) McCoy passed from this life on 7 July 1993 (see Herpetologica 50:379–382 for traditional obituary), yet through our recollections he lives on; our memories, in a sense, and his influence upon us, provide him immortality. The following collection of anecdotes from friends and colleagues embodies Jack as we knew him. Ranging from personal to field experience, each submission we received has been edited and presented accordingly.

Living in close quarters, sometimes under adverse conditions, exposes character; in a herpetologist it often unleashes a competitive spirit with, in Jack's case, tolerance and humor often in evidence:

"In June 1985, Ellen Censky, Paul Freed, Jack, and I went to Belize. We split up into two field teams; it was suggested that I be given a handicap since Ellen was my field partner. Jack and Paul returned with a couple of lizards. Ellen and I brought back *Sphenomorphus cherriei*, *Micrurus diastema*, *Drymarchon corais*, and a large *Bolitoglossa dofleini*, a new record for the country. We accepted bragging rights for the day's collections, brought out the 6 foot *Drymarchon*, and draped it across our shoulders for Jack's trophy picture. I first saw that photograph as a special label on a bottle of wine given to my wife on her 40th birthday. When confronted by the photo, supposedly taken in Australia of me and a lady herpetologist, all I could say was 'I don't remember any lady herpetologist in Australia.' One can imagine the discussion that followed; we were in a room filled with herpetologists. Jack, as he often did, got the last laugh." (Ray E. Ashton, Jr.)

"In 1964, P. Maslin, C. Carpenter, D. Tinkle, O. Cuellar, B. Clarke, Jack, and I went to the islands in the Sea of Cortez. On that trip I learned of Jack's abilities as swimmer, diver, lizard chaser, and humorist. Aboard ship Jack supplemented our diet from the sea; he and Orlando often skin dived for groupers on the fringes of the islands. Jack often swam with no clothes on. As a result, he developed a good tan, took on the appearance of a Mexican, and often sang like one, especially after a few beers." (James R. Dixon)

"During a field trip in Virginia, meal preparation was a group effort. Three days into the week Jack fixed a large pot of spaghetti. We all ate heartily, and there were few leftovers (or so we thought). The next morning there was more spaghetti in the pot than we had before supper; it seemed to multiply on its own. For the next three days Jack taught us that one could always eat spaghetti, even at breakfast!" (Joe and Wendy Mitchell)

"Jack was nearly always reserved in reaction and comment. At Reelfoot Lake, he, Dick Vogt, and I set out across the main southern basin of the lake. Dick ran the motor on the Carnegie's boat at full throttle, appropriate in most big lakes, but this lake is replete with barely submerged stumps and other snags. As the boat gathered speed, the prop would hit a stump and come flying out of the water with a whine. Jack simply frowned at Dick. Dick finally responded with 'Well, what do you want us to do—take a leisurely tour of the lake or get there and catch turtles?' The motor continued to function and survived nearly a dozen similar insults; Jack displayed only a few mildly 'ruffled feathers.'" (Michael A. Ewert)

With many of us, we suspect, the persona presented at work is a mere reflection of our true persona. With Jack, however, one noted little change between home, work, or play. One such example was suggested by Alvin Braswell.

Photograph courtesy R. B. Bury.

"In 1982, John Cooper and I arrived at Cape Hatteras the day Jack and Patsy McCoy were leaving (their fishing trip had not been too successful). As we arrived, two fishermen were dragging hugh bluefish across the road in front of the motel. Cooper and I grabbed our rods, and headed for the beach—following the drag marks in the sand. I had hardly gotten my bait into the water when a gentle bite turned into a tug-of-war that must have lasted 10 minutes. As I hoisted the bluefish out of the surf, I commented to Cooper that this quick catch was going to tear Jack up. Just then we saw Jack (carrying two large bluefish) and Patsy coming toward us. While he and Patsy had stopped to talk with some fishermen, 3 fifteen-pound chopper blues scooted up the beach right at their feet! My quick catch, coupled with the beach assault, would have driven many fishermen into a frenzied kicking of sand and shouting of profanity, but Jack handled it in the calm, rational manner that was typical of his approach to life. He always derived as much joy from the fish that others caught as he did from his own."

Straight-forward in his approach to inter-personal relationships, Jack became close personal friend, mentor, and confidant to many of us. Several examples of his sensitivity, patience, and ability to cooperate under trying circumstances were provided among the tributes we received. In addition to the excerpts provided below, we received contributions expressing similar sentiments from R. Bruce Bury, Roger Conant, and Hobart M. Smith; space limitations preclude our including them all.

"Jack was both a vigorous and prominent scientist, and a compassionate human being. When a museum curator felt entitled to my entire dissertation collection, even though he had provided no previous material assistance, I told him that my collection would go to Carnegie Museum. It specialized in herps from the region, and Jack had offered to reimburse me for the collection;

reimbursement was critical—I needed to pay my dissertation typist. The curator threatened to reject my dissertation unless Jack withdrew his offer. Jack withdrew his offer accordingly, then called to say that he would purchase the collection six months after my dissertation was approved. The curator was appeased, my needs, and the needs of the Carnegie, were met. All accomplished with neither confrontation nor humiliation! Jack found the means to solve problems diplomatically, yet effectively." (Dave Morafka).

"Jack was truly dedicated, and his influence will be felt for some time. In addition to his curatorial duties, he dedicated a lot of effort to the herpetological societies. He was a gentle soul, always willing to help others. Recently, when David Auth and I worked with Jack on a biography and bibliography of Wilfred T. Neill, I could tell he was delighted, in his quiet and unassuming way, whenever he located a reference or tidbit on Neill that we had not yet found. It was a pleasure to be skunked by Jack!" (Ernie Liner).

"A calming voice, a steady presence. Our friendship was fueled by shared friends and museum and societal business. Conversations, often as not, were over the phone or asides during committee meetings. These shared moments are remembered because of their helpfulness, but more fondly remembered are the all too infrequent field and social ones—an exchange of verbal barbs as we put on our boots to search for *Clemmys muhlenbergii* in an Erie Co., Pennsylvania, bog; sipping a pint in the Rutherford College pub and watching the frenzied and competitive interactions of colleagues and friends; and other flashes of conviviality as our professional paths brought us together and led us apart." (George R. Zug).

"I knew Jack as a person possessing honesty and integrity. He was never afraid to express his feelings or to admit his own shortcomings; he could be extremely blunt, but he was never malicious. I could always trust Jack for as direct and lucid an explanation of any situation as was possible. Jack was truly my mentor; whatever successes I achieve are due in large measure to his steady encouragement. Jack knew very well of the condition that would cause his death, and he faced it with dignity and quiet courage. He lived life fully to the very end, and that is the legacy I carry with me." (Andy Price).

"Jack was an easy person to work with; he was an ideal collaborator always pulling his share, or more. Distance was never a problem; Jack was a great correspondent and always responded in a timely fashion. He was also the consummate editor, often sending manuscripts back with more marginalia than text. He admitted to having a 'heavy hand,' but his recommendations always made significant improvements in quality and presentation." (Jeff Lovich).

"I admired his efforts at training people from other countries. Interaction with specialists is not as readily available abroad as it is here. I also remember Jack's sense of humor; it was so subtle that it was often some time after a conversation had concluded that one realized a response had been 'tongue in cheek.' His humor supplemented his willingness to support training, his kindness, and his patience." (Carl Gans).

"Jack was born in Texas, grew up in Oklahoma, and spent over half his life trying to get out of Pittsburgh. Once while I was a postdoc at Carnegie and preparing to make plane reservations for a field trip to Mexico he suggested I '...make the reservation Miami-Cozumel-Pittsburgh...I'll drive you to the airport.' It was late February, cold and dreary in Pittsburgh. We drove to Florida, stopped at Little Talbot Island State Park, bought a sack of fresh oysters, raked up a bushel of clams, bought a bottle of Tequila, and sat on the beach, fished, ate, and talked for two days—in warm weather." (Richard C. Vogt).

"In addition to his endless patience, his wonderful sense of humor, and his willingness to help others, Jack was an accomplished scientist in and out of the field of herpetology. I remember having lunch with him once at a small restaurant. He bit into a fish sandwich and, with joyous rapture, rattled off the scientific name of the fish he was eating! 'Are you serious?' I asked. 'How can you tell what it is just by biting into it.' His hearty laugh told me that the fish wasn't the only one who got 'caught.'" (Paul Freed).

"Jack supported the efforts of many an aspiring herpetologist; our relationship began in 1960, and continued throughout the development of my career. His support and advice guided me through a stint in the Peace Corps and a four-year term with the U.S. Navy (in Spain). While I was overseas, Jack answered my questions—often delivered twice weekly by post—and kept me "in touch" with the world, herpetological and otherwise. When I returned to the U.S., he guided me to my first professional position. Later he would edit manuscripts, write letters of recommendation, support grant applications, and provide meals and lodging at his home. I knew him well, considered him my best friend, yet never got the chance to know him well enough. In agreement with many of those who contributed to this tribute, I, too, shall feel the loss for many years to come." (Stephen D. Busack).

"You gotta be tough to be a herpetologist,' 'Patience is a virtue,' 'No teasa da curator'—the three rules in the Section of Amphibians and Reptiles, Carnegie Museum of Natural History. Jack was my teacher, my boss, my mentor; most of all, he was my friend. It will not be easy for me to get used to the idea that Jack is gone and that a source of profound advice and direction will no longer be there. We'll all miss you, Jack." (Ellen J. Censky).

SSAR World Wide Web Page

SSAR has expanded its presence in cyberspace. In addition to the on-line postings for *Herp. Review* mentioned elsewhere in this issue, SSAR has begun a World Wide Web Page. Set your browser to

http://falcon.cc.ukans.edu/~gpisani/SSAR.html

and check us out. The site still is under construction, but more useful things are being added weekly. FORMER OFFICERS, EDITORS, COMMITTEE MEMBERS: please review the file "SSAR Officers and Editors" to check that your data are up-to-date. This file will be used eventually in a history of the Society. Send changes to George Pisani (gpisani@falcon.cc.ukans.edu).

LEGISLATION & CONSERVATION

Call for information on the status of amphibians and reptiles: This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information especially on the State and Province level. Please send pertinent information to the Section Editor.

USA: Department of the Interior: The U.S. Fish and Wildlife Service was petitioned on 15 September 1994 by the Biodiversity Legal Foundation (P.O. Box 18237, Boulder, Colorado 80308-1327, USA, tel. 303-442-3037) to list the Amargosa toad (*Bufo nelsoni*) as Endangered. The Amargosa toad is endemic to the Oasis Valley in Nye County, Nevada. According to BLF's petition, toads are known from only nine sites. The toads are dependent on springs within the valley. Grazing, exotic catfish, off-road vehicles, the battle for water rights, and a human population that has increased from 300 to 1800 in 30 years are included as threats. The USFWS currently lists *B. nelsoni* as C1 (Federal Register, Vol. 59, No. 219, 15 Nov 1994).

The USFWS has 90 days from the date of the petition was filed to rule whether the petition is valid, followed by one year to rule on the proposed listing. Those with comments should address them to: *Ms. Sherry Barrett, USFWS, 4600 Kietzke Lane, Bldg. C, Reno, Nevada 89502, USA. Submitted by: Ronald W. Marlow, 1634 Serenada Ave., Las Vegas, Nevada 89109-2509, USA.*

USA: Department of the Interior: The USFWS has issued a final rule listing the goliath frog (*Conraua goliath*) as Threatened. This huge amphibian is narrowly distributed in Central Africa and is vulnerable to commercial collection and to other problems (Federal Register, Vol. 59, No. 235, 8 December 1994).

USA: Department of the Interior: The USFWS has issued a final rule listing the arroyo southwestern toad (*Bufo microscaphus californicus*) as Endangered. The arroyo toad occurs exclusively in streams in southern California and northwestern Baja California, México. The arroyo toad has been extirpated from an estimated 75% of its former range. Threats to the survival of the species include habitat degradation, predation, and small population sizes (Federal Register, Vol. 59, No. 241, 16 December 1994).

USA: The Humane Society of the U.S. A report entitled, "Live Freshwater Turtle and Tortoise Trade in the United States" is available free. Ask for the report on official university, non-profit, or herp organization stationary. Write to: *Teresa Telecky, HSUS, 2100 "L" Street NW, Washington, D.C. 20037, USA. Submitted by: Allen Salzberg, 67-87 Booth St. #5B, Forest Hills, New York 11375, USA.*

Convention on International Trade in Endangered Species (CITES): The CITES Secretariat issued notification to members to suspend imports of the following herptile species: Oriental rat snake (*Ptyas mucosus*) [Peoples Republic of China and Indonesia], Indian bullfrog (*Rana tigerina*) and Asian bullfrog (*R. hexadactyla*) [India], ball python (*Python regius*) [Togo], and pancake tortoise (*Malacocherus tornieri*) [United Republic of Tanzania]. The countries from which these species originate have failed to implement the recomendations of the CITES Standing Committee such as creating national legislation for the protection of the species, and/or initiating studies to evaluate harvest levels and establish scientifically based sustainable-use management programs. Therefore, in accordance with the responsibility of the United States under CITES, and effective immediately and until further notice from the USFWS, no shipments of these species may be imported into the U.S. (Federal Register, Vol. 59, No. 234, 7 December 1994).

USA: Florida: The Florida Game and Freshwater Fish Commission (GFC) is proposing a legislative package to restructure current licenses and fees. The GFC proposes to increase the Venomous Reptile permit from $5 to $25, and increase the license fees to exhibit or sell animals. Permits for scientific collection which are currently issued free would cost up to $75. Currently, anyone can collect any quantity of unprotected herptiles in Florida without a license or permit. The GFC proposes to require anyone collecting more that two specimens at one time to purchase a license of $11 annually for residents, $150 annually for non-residents, or $25 for 10 days for non-residents. To comment or obtain more information contact: *Paul Moler (904) 955-2230 or Kevin Enge (904) 627-9674.*

CITES: At the Conference of CITES Parties held in Ft. Lauderdale, Florida, USA, 7–18 November 1994, the USFWS submitted a proposal to list all species of North American box turtles (genus *Terrapene*) in CITES Appendix II (except *T. coahuila*, which is already on Appendix I). Appendix II species are those that may become threatened with extinction unless trade is properly managed and regulated. The proposal was adopted by consensus. Any future exports of box turtles by the United States or other CITES Parties will require a CITES export permit from OMA (U.S. Department of the Interior, CITES Update #31, December 1994).

At the CITES conference, a resolution was adopted that establishes new standards, procedures, and requirements for the tagging of all crocodilian skins in international trade. New guidelines for evaluating marine turtle ranching proposals were also adopted. Specifically, these guideline require a comprehensive biological assessment and monitoring of the population to be ranched, effective implementation of a national program for turtle conservation, development and implementation of regional protocols for cooperative conservation among range states, and adequate controls by proponents and importing parties to ensure the trade in ranched turtles does not stimulate illegal trade.

Changes in status were approved for the following species of reptiles and amphibians (the new status follows each species in parentheses). Egyptian tortoise (*Testudo kleinmanni*) (App. I); black caiman (*Melanosuchus niger*), Ecuador population (App. II), Nile crocodile (*Crocodylus niloticus*), Zaire, Tanzania, Madagascar populations (App. II) and Somalia population (App. I); estuarine crocodile (*C. porosus*), Australia and Indonesia populations (App. II); all tuataras (genus *Sphenodon*) (App. I); Golden toad (*Bufo periglenes*) (App. I); and golden mantella (*Mantella aurantiaca*) (App. II).

USA: Virginia: An example of anti-environmental sentiment was unfortunately recently enacted in Virginia. The Chesapeake City Council, without objection from state wildlife officials, responding to a strong landowner rights movement, trespass concerns, and the ignorance and fears of the local public, demanded that researchers at Old Dominion University (ODU) and Christopher Newport University stop an eight-year radio-telemetry study of state-endangered canebrake rattlesnakes (*Crotalus horridus atricaudatus*). The study was being conducted on a natural population in a city-owned park. Adjacent landowners and the Chesapeake Farm Bureau became angry when they learned that the home ranges of the snakes included private property. The study was funded by private donations to the Virginia Department of Game and Inland Fisheries Nongame Program and was supporting several graduate students at ODU. Future funding, previously assured, is now in jeopardy for political reasons.

SSAR Conservation Committee.

CURRENT RESEARCH

The purpose of **Current Research** is to present basic summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA. Comments and suggestions are also welcome.

Ecology

Using data collected between 1988–1992, Capula and Luiselli compared the fecundity of 12 cryptically colored adders to that of nine melanistic females. The melanistic females had a significantly higher rate of reproduction which the authors attributed to their superior ability to thermoregulate in the cool high altitudes.

CAPULA, M., AND L. LUISELLI. 1994. Reproductive strategies in alpine adders, *Vipera berus*. The black females bear more often. Acta Œcologia 15(2):207–214.

A recent paper by Vitt and Caldwell examines resource utilization and niche breadth for a community of two lizards species and eight frog species living in the Amazon forest leaf litter. Feeding guilds, activity patterns, and prey type and size are compared for the ten species.

VITT, L. J., AND J. P. CALDWELL. 1994. Resource utilization and guild structure of small vertebrates in the Amazon forest leaf litter. J. Zool., Lond. 234:463–476.

Three recent papers discuss different aspects of varanid biology and ecology. Tsellarius and Men'shikov determined that scent-marking behavior in *Varanus griseus* is used to identify age, sex, and even individuals within a community. They also examined seasonal scent-marking behavior. Yeboah compared the body length-weight relationship, basking and roosting temperatures, feeding habits, and behavior of two African monitors. Pianka discusses the evolution of body size in two subgenera of varanids, as well as many other aspects of their ecology. A food web for 40 species of Australian desert lizards is also presented.

TSELLARIUS, A. YU., AND YU. G. MEN'SHIKOV. 1994. Indirect communication and its role in the formation of social structure in *Varanus griseus* (Sauria). Russian J. Herpetol. 1(2):121–132

YEBOAH, S. 1993. Aspects of the biology of two sympatric species of monitor lizards *Varanus niloticus* and *Varanus exanthematicus* (Reptilia, Sauria) in Ghana. Afr. J. Ecol. 32:331–333.

PIANKA, E. R. 1994. Comparative ecology of *Varanus* in the Great Victorian Desert. Aust. J. Ecol. 19:395–408.

Biogeography

Kaiser et al. used allozymes of the diverse anuran genus *Eleutherodactylus* to examine the biogeography and phylogenetic relationships of the Lesser Antillean island arc plus Trinidad and Tobago. They conclude that *Eleutherodactylus* has colonized these islands from both South America and the Greater Antilles.

KAISER, H. T., F. SHARBEL, AND D. M. GREEN. 1994. Systematics and biogeography of eastern Caribbean *Eleutherodactylus* (Anura: Leptodactylidae): Evidence from allozymes. Amphibia-Reptilia 15:375–394.

Molecular Biology & Systematics

Molecular data may not be as neutral as previously thought. Malhotra and Thorpe examined the morphological and mtDNA variation of two species of *Anolis* on separate islands and found parallels between the two sets of data. Furthermore, the data sets were correlated with ecological gradients, suggesting mtDNA evolution may involve environmental selection.

MALHOTRA, A., AND R.S. THORPE. 1994. Parallels between island lizards suggests selection on mitochondrial DNA and morphology. Proc. R. Soc. Lond. B 257:37–42.

A new species is described, another resurrected, and three new synonyms of Madagascan *Phelsuma* are recognized in a revision of these lizards by Raxworthy and Nussbaum. A taxonomic key to the twenty Madagascan *Phelsuma* is also presented.

RAXWORTHY, C. J., AND R. A. NUSSBAUM. 1994. A partial systematic revision of the day geckos, *Phelsuma* Gray, of Madagascar (Reptilia: Squamata: Gekkonidae). Zool. J. Linn. Soc. 112:321–335.

Using both DNA sequence and allozymes, de Queiroz and Lawson estimate phylogenetic relationships of *Thamnophis*. The two methods yielded different phylogenies, whereas combining the data sets gives an almost fully resolved tree. The paper includes a discussion of combining molecular data from different techniques in order to gain better resolution of phylogenetic trees. Systematic conclusions include additional data supporting the placement of the problematic species *validus* in the genus *Thamnophis*.

DE QUEIROZ, A., AND R. LAWSON. 1994. Phylogenetic relationships of the garter snakes based on DNA sequence and allozyme variation. Biol. J. Linn. Soc. 53:209–229.

Source for Skin Toxins in Dendrobatids

Prey items have long been suspected of being the source of skin alkaloids found in dart-poison frogs, but conclusive proof was lacking. In a series of experiments John Daly and colleagues have shown that insect prey are the source of some, if not all, toxic skin alkaloids in these frogs. In the first paper, frogs were fed a diet of either fruit flies or native leaf-litter arthropods for a period of seven months. Skin alkaloids were virtually absent among control frogs, but abundant in frogs raised on leaf-litter arthropods. In the second paper, captive frogs were fed fruit flies dusted with various alkaloids, or ants (*Monomorium pharaonis*). The frogs were able to accumulate most of the skin alkaloids and store them for extended periods, although some toxins were not accumulated.

DALY, J. W., H. M. GARRAFFO, T. F. SPANDE, C. JARMILLO, AND A. S. RAND. 1994. Dietary source for skin alkaloids of poison frogs (Dendrobatidae)? J. Chem. Ecol. 20(4):943–955.

DALY, J. W., S. I. SECUNDA, H. M. GARRAFFO, T. F. SPANDE, A. WISNIESKI, AND J. F. COVER, JR. 1994. An uptake system for dietary alkaloids in poison frogs (Dendrobatidae). Toxicon 32(6):657–663.

Bibliography to German Herpetological Publications

The Deutsche Gesellschaft für Herpetologie und Terrarienkunde (German Society for Herpetology and Herpetoculture) recently published an index to the German publications *Salamandra, Elaphe, Elaphe N.F., Herpetofauna, Sauria,* and *Bücher*. Citations are taxonomically cross-referenced. For more information contact Andreas Mendt, DHGT, Postfach 1421, Locher Str. 18, D-53351 Rheinbach, Germany.

Biodiversity & Conservation

The status of the Texas horned lizard (*Phrynosoma cornutum*) was examined through field surveys of sites selected based on museum specimen records and through interviews and surveys completed by 700 Texans. The study found that *P. cornutum* has declined in eastern and central Texas, while populations appear healthy in west Texas. Declines were linked more to habitat alteration and pesticides than to introduced fire ants. This papers presents a relatively quick way to collect information on long-term population trends for conspicuous species.

DONALDSON, W., A. H. PRICE, AND J. MORSE. 1994. The current status and future prospects of the Texas horned lizard (*Phrynosoma cornutum*) in Texas. Texas J. Sci. 46(2):97–113.

Amphibian Declines

The status of amphibian populations in the Commonwealth of Independent States is reviewed in a paper appearing in the journal *Alytes*. The paper includes a table summarizing causes of declines for 25 species as well as an important list of Russian literature.

KUZMIN, S. L. 1994. The problem of declining amphibian populations in the Commonwealth of Independent States and adjacent territories. Alytes 12(3):123–134.

The Koordinationsstelle für Amphibien- und Reptilienschutz in der Schweiz (Coordination Center for the Protection of the Amphibians and reptiles in Switzerland) has completed an assessment of approximately 8000 amphibian spawning sites. Using a formula to evaluate each site, 891 sites were determined to be of national importance. This study presents many ideas which may be useful for other amphibian management programs.

BORGULA, A., P. FALLOT, AND J. RYSER. 1994. Inventar der amphibienlaichgebiete von nationaler bedeutung [An inventory of the amphibian breeding sites of national importance in Switzerland]. Schriftenreihe Umwelt - Natur und Landschaft (233):1–75.

A New Lissamphibian Lineage

An analysis of the first complete albanerpetontid amphibian (including traces of skin and possible male courtship glands) support the recognition of a distinct lissamphibian lineage. These salamander-like amphibians are suspected to be the sister group to Caudata and Salienta. A new genus and species are also described.

MCGOWAN, G., AND S. E. EVANS. 1995. Albanerpetontid amphibians from the Cretaceous of Spain. Nature 373:143–145.

Chameleon Eyes

Chameleons have long been recognized for their ability to move their eyes independently, but a recent study indicates chameleon eyes are structurally different than those of all other vertebrates. Not only do chameleons have higher image magnification than any other vertebrate eye scaled to the same size, their lens has a negative refractive power.

OTT, M., AND F. SCHAEFFEL. 1995. A negatively powered lens in the chameleon. Nature 373:692–694.

LAND, M. F. 1995. Fast-focus telephoto eye. Nature 373:658–659.

Herpetozoa

The Österreichische Gesellschaft für Herpetologie (Austrian Society for Herpetology) publishes the journal *Herpetozoa*. Original articles, reviews, notes, and book reviews in either English or German are considered for publication. Membership dues are $35 (ATS 350, DM 50), regular members or $70 (ATS 700, DM 100), sustaining members (VISA cards are accepted). More information may be obtained by writing ÖGH, Naturhistorisches Museum Wien, Herpetologische Sammlung, Burgring 7 - Postfach 417, A-1014 Wien, Austria. The contents of a recent issue are:

ARTICLES

Distribution and Abundance of *Emoia slevini* (Scincidae) in the Mariana Islands

The Mariana Islands have a depauperate oceanic herpetofauna (Rodda et al. 1991) and the only endemic reptile is *Emoia slevini* (Brown and Falanruw 1972). The range given for this species in a recent revision (Brown 1991), was simply, the Mariana Islands. Recent information (Rodda et al. 1991) indicated that this species has not been recorded from all islands in the Mariana archipelago. Rodda et al. (1991) summarized the distribution of *E. slevini* and listed this species as occurring on six (Cocos, Guam, Rota, Tinian, Alamagan, and Asuncion) of the 14 islands that have been herpetologically surveyed. They also predicted, based on a species richness/island-size relationship, that *E. slevini* should occur on an additional three islands (Anatahan, Pagan, and Agrihan).

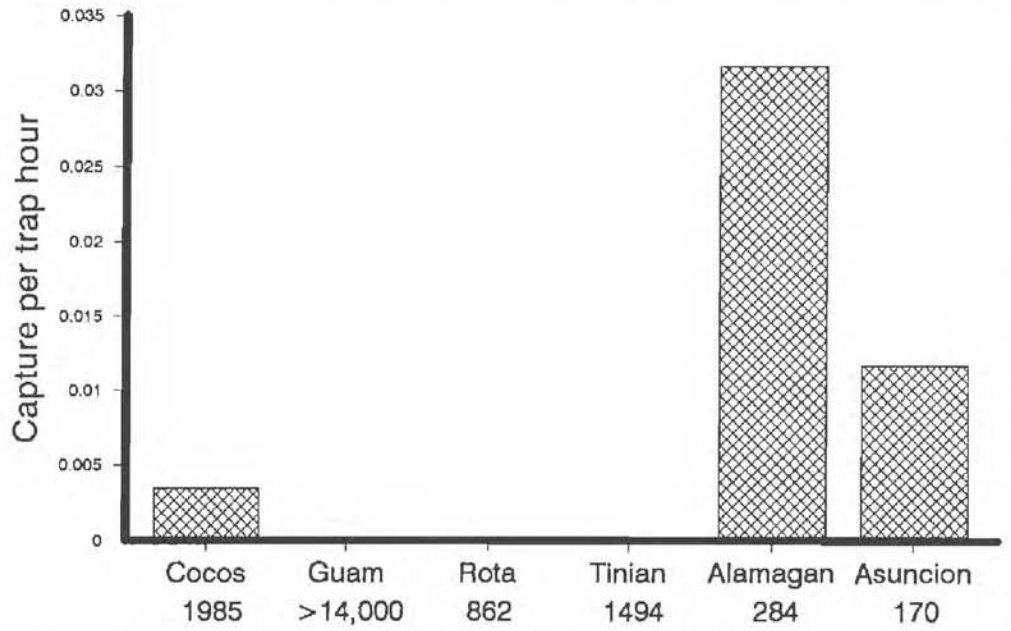
Prior to 1988, lizards in the Mariana Islands were collected by hand or rubberband. Since then, the use of adhesive boards (Bauer and Sadlier 1992; Rodda et al. 1993) has largely replaced these traditional collecting techniques for diurnal lizards and provided a mechanism to estimate relative abundances. Many of the islands in the Mariana archipelago have been surveyed using this technique and three islands (Cocos, Alamagan, and Asuncion) have had *E. slevini* recorded by this method. In order to assess possible population density differences between these islands, we used catch-per-unit-effort (CPUE) data based on mean number of *E. slevini* captured per daylight trap-hour (Rodda et al. 1993).

Asuncion is represented by a single specimen collected in 1988. Additionally, Falanruw (1989) observed three large *E. slevini* (date uncertain but probably mid-1970's) and a probable clutch of eggs in 1975 on Asuncion. Alamagan is represented by 21 specimens collected in 1988. Tinian has a single specimen collected in 1946, and Rota, two specimens collected in 1945. Recent surveys on both Tinian and Rota (Wiles et al. 1989; 1990) failed to document this species, but in 1991, T. Case (pers. comm.) observed two probable *E. slevini* on Rota. Guam is represented by a single specimen collected in 1945 and extensive surveys between 1984 and the present have failed to yield any further specimens. Between 1970 and 1980, 27 specimens (23 of which were in the type series) were collected on Cocos. Between 1988 and 1993, an additional 9 specimens were collected, yielding a total for the island of 33. The total number of specimens for the Mariana Islands is 59.

Recently, *E. slevini* has been collected from three islands in the Mariana archipelago (Cocos, Alamagan, and Asuncion). Historical records extend this range to an additional three islands (Guam, Rota, and Tinian), but, with the exception of two sight records on Rota, recent surveys suggest that this species may be extinct on these islands. Recent vulcanism on two islands with predicted populations (Anatahan and Pagan) may have eliminated populations there. On the islands with known extant populations, Alamagan appears to have the densest population, and Cocos, the least dense.

In addition to a much higher CPUE (Fig. 1) for Alamagan, an additional line of evidence suggesting that *E. slevini is* more abundant on Alamagan than other sampled islands is the proportion of the total catch that was *E. slevini*. On Alamagan this was approximately 20%, compared to 8% (Asuncion) and 1% (Cocos). We interpret these data as Alamagan having a denser population of *E. slevini* than the other two islands. Reasons for this abundance on Alamagan may be related to a large feral ungulate population that deposits substantial quantites of dung, thereby supporting an enormous dipteran population.

A factor that could influence abundance of *E. slevini* may be the richness of the diurnal lizard community on these islands. Including *E. slevini*, Cocos has six species of scincids, and Alamagan and Asuncion each have three scincids. While the greater number of scincid species on Cocos Island may account for lowered abundance of *E. slevini*, the greater abundance of *E. slevini* on Alamagan compared to Asuncion (see Fig. 1 and above) may not be due to differences in scincid community richness.



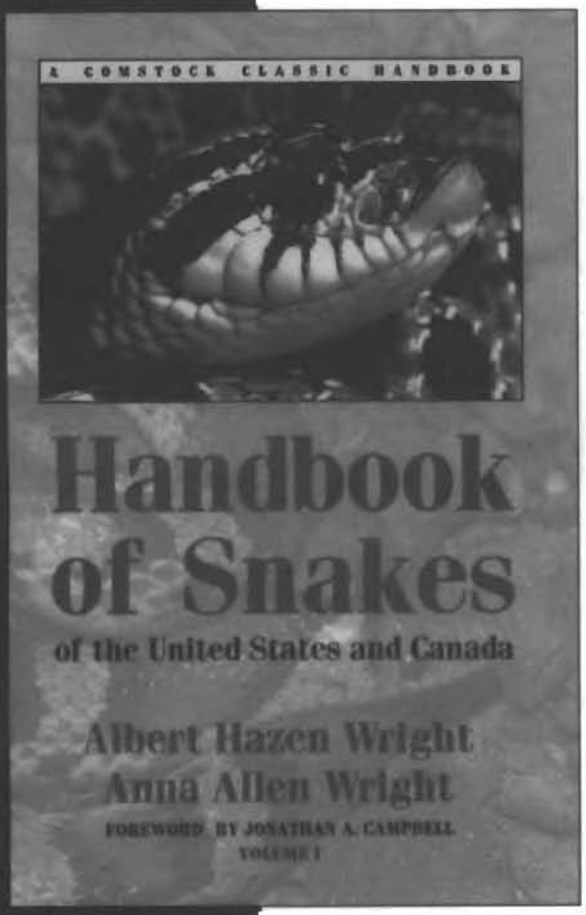


FIG. 1. Mean number of *Emoia slevini* captured per daylight trap/hour (CPUE) 1988–1993 for islands from which specimens have been collected. Numbers below each island name are trap-hours expended. Islands are arranged geographically (S to N). Effort for Rota includes trapping reported in Wiles et al. (1990).

The status of populations on the other three islands in the Marianas where *E. slevini* has been recorded (Guam, Rota, and Tinian) is problematical. The Guam population is likely extirpated as in excess of 14,000 trap-hours have been expended since 1988 in various habitats and no further specimens have been collected. Rota appears to have very low population densities or highly localized populations. The Tinian population may be extirpated or have, as yet undiscovered, localized populations similar to Rota.

Reasons for the decline of or failure to develop denser populations on Guam, Rota, and Tinian are enigmatic. It has been suggested that introduced species have negatively impacted *E. slevini* (Rodda et al. 1991), but the patchy presence of potentially detrimental introduced species does not cor-

Third Edition

ALBERT HAZEN WRIGHT AND ANNA ALLEN WRIGHT

Foreword by Roy McDiarmid

"Within the 583 pages of text is compressed practically everything a collector needs to know to identify his or her catch. Form, color, size, voice, habitat, habits, and geographic range are conscientiously described for every species."

relate with known distributions of *E. slevini*. *Carlia* cf. *fusca* (an aggressive kleptoparasitic skink), *Suncus murinus* (a shrew), and the colubrid *Boiga irregularis* (a skink predator), occur on Guam. Dates of introduction on Guam of these species (*C.* cf. *fusca*, mid-1960's, McCoid [1993], Rodda and Fritts [1992]; *S. murinus*, 1953, Barbehenn [1962]; *B. irregularis*, late 1940's, Rodda et al. [1992]) occurred after the capture of the only specimen of *E. slevini*. However, during the period that these introduced species irrupted (1950–1985), few herpetological surveys were conducted. *Carlia* cf. *fusca* was probably introduced on Cocos in the late 1980's and is currently sympatric with *E. slevini* in forested areas. Both *S. murinus* and *B. irregularis* have not been introduced on Cocos. On Rota, *C.* cf. *fusca*, *S. murinus*, and *B. irregularis* are absent, but *E. slevini* is still rare. On Tinian, *B. irregularis* is not present, but *C.* cf. *fusca* and *S. murinus* are. No discernable pattern of introduced species having island-wide effects on populations of *E. slevini* is evident.

The relationship between *E. slevini* and its habitat requirements is obscure. It has been suggested that habitat alterations related to human activities may have played a role in the current intra-island distributional patterns of reptiles in the Mariana Islands (Wiles et al. 1989). On Alamagan and Asuncion, many specimens have been collected or observed in forested ravines. On Cocos, all specimens have come from a forested area. While it is certain that agricultural and destructive practices associated with WWII have affected the intra-island ranges of various species of lizards in the Marianas, sufficient primary and relatively undisturbed secondary habitats remained that should have allowed the persistence of *E. slevini*. At a minimum, at least 5% (2700 ha) of Guam remains as tall forest and substantial tracts adjacent to the only site of collection for *E. slevini* still exist. Tinian has approximately 5% (500 ha) of tall forest at present (Wiles et al. 1989). Rota has approximately 60% (5000 ha) of tall forest at present (Wiles et al. 1990). These areas contrast with the persistence of this species on Cocos with an area of 37 ha. Cocos Island has endured the development of a coconut plantation prior to WWII, construction of a U.S. military installation (formerly occupying approximately 1/4 of the island), two resorts (occupying a total of 1/2 the island), and at least three typhoons since 1949 that have overwashed the island (Neubauer and Neubauer 1981; per. obs.). Only about 1/4 of the island remains as regenerated atoll forest. This suggests that *E. slevini* may be able to persist (and rebound) after significant environmental perturbations, whatever the causes.

The total surface area of islands occupied by the species is less than 1900 ha (Alamagan = 1130 ha, Asuncion = 730 ha, Cocos = 37 ha). If preferred habitats are relatively undisturbed forested areas, then the actual range might be considerably less. The low population density and extremely limited distribution of the Cocos Island population (9 ha of forest) suggest that this population may be vulnerable to extirpation.

Acknowledgments.—Portions of this investigation were supported by the Endangered Species Conservation Program, Project E4 (to Guam). Ted Case generously contributed observations. Rebecca Hensley and Walter C. Brown kindly reviewed drafts of the manuscript. Robert Cruz, Earl Campbell III, and Rebecca Hensley aided in surveys on Cocos Island.

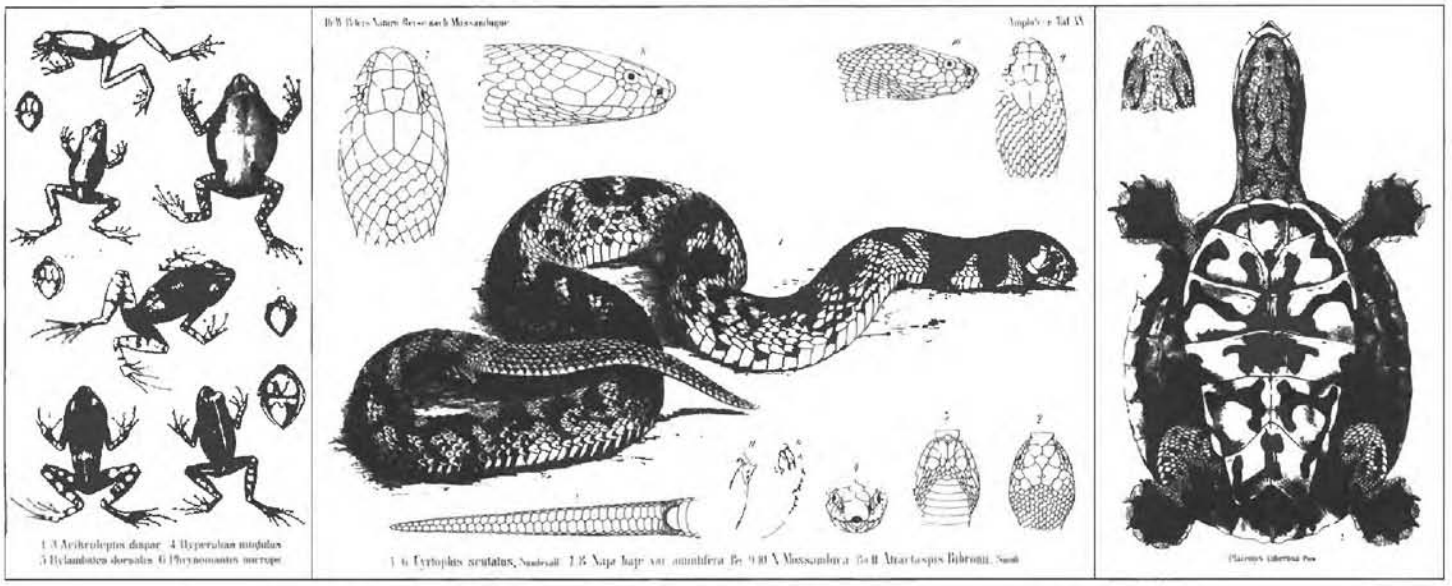
A New Facsimile Reprint from the Society for the Study of Amphibians and Reptiles



THE HERPETOLOGICAL PUBLICATIONS OF WILHELM PETERS

With an Extensive Introduction, Annotated Bibliography, and Synopsis of Taxa by
AARON M. BAUER, RAINER GÜNTHER, AND MEGHAN KLIPFEL

WILHELM C. H. PETERS, the leading German herpetologist of the 19th century, was Director of the Zoological Museum in Berlin. His main interest was in systematics and anatomy, but his primary contribution to herpetology was the description of **122 NEW GENERA AND 649 NEW SPECIES FROM THROUGHOUT THE WORLD**—mainly Africa, Asia, Australia, and South America—representing 56 families of amphibians and reptiles, including 32 hylid frogs, 7 turtles, 29 agamids, 32 geckos, 111 skinks, 3 monitors, 5 pythons, 118 colubrids, and 10 vipers. About 65% of these species are valid today.

Despite their continuing importance, Peters' publications are not generally available. This reprint includes all of his herpetological books and papers, 173 titles in all, with outstanding plates containing hundreds of individual figures. These titles include four major works: monographs on the uropeltid snakes of South Asia, the microteiid lizards of Tropical America, a catalogue of Indoaustralian amphibians and reptiles, and Peters' 239-page book on the herpetology of Mozambique (Southeast Africa), based on his own expedition in 1842–1848. Most papers are in German, with others in Italian, English, Latin, Swedish, and French. Since many of Peters' taxonomic papers were printed in a small format, by modest reduction to about 75% of original size it is possible to print four of them per page of facsimile. As a result, **THIS BOOK COMPRISES 1562 PAGES OF ORIGINAL TEXT AND 114 PLATES.** Peters' book on Mozambique, however, is printed in full-page size. Added to these facsimiles is an introduction containing an illustrated biography of Peters, an annotated bibliography of his papers, a synopsis of taxa described by Peters that lists types, type localities, current names, and many other essential details, and an extensive cross-index to the volume.

Specifications: 725 pages, 9 photographs, map, 114 plates, index. Format 8 1/2 × 11 inches (21.5 × 28 cm). Clothbound. To be published September 1995. ISBN 0–916984–35–4. Some sample illustrations, greatly reduced in size, are shown below.

THE HERPETOLOGICAL PUBLICATIONS OF WILHELM PETERS

• Price to SSAR members *before publication* . . . . US$55 • Price to Institutions and Non-members $75

Shipping: In USA, add $2; non-USA, add $4.

Send orders to Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103, USA (*Telephone*: area code 314, 977–3910 or –3916; *fax*: 314, 977–3658). Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks (include an additional amount to cover bank conversion charges) or by International Money Order. Orders may be charged to MasterCard or VISA (provide account number and expiration date). SSAR membership details and a complete list of Society publications can be obtained on request to Dr. Aldridge.

Sumichrast's Skink (*Eumeces sumichrasti*) in Quintana Roo, México: A Correction

In 1963 (McCoy and Miller 1963) I reviewed the distribution of the Neotropical lowland skink *Eumeces sumichrasti* (Cope), and reported the first locality record for the species from the northern part of the Yucatan Peninsula, México. That locality, which was reported as X-can, Quintana Roo, was erroneously placed in Yucatan by Smith (1992:151) on the basis of information in Flores Villela and Gerez (1988:216–217). The confusion resulted from duplication of the place name X-can, which is a common problem when dealing with Mexican localities. In this case, however, the history of the story of the two X-cans, which was related to me by E. C. Welling M. (pers. comm.), is as follows.

The original village of X-can, Yucatan was a long-established trading center in the isolated northeastern part of the Yucatan Peninsula. When the Territory of Quintana Roo was created in 1902 from the eastern section of the state of Yucatan, the boundary was placed west of X-can, thus X-can was in Quintana Roo. This suited the villagers perfectly. The Yucatec Maya are fiercely independent people and the territorial capital (Ciudad Chetumal) was many kilometers to the south and relatively inaccessible. During the 1950's the solution of territorial disputes between the State of Campeche and the Territory of Quintana Roo resulted in realignment of the boundary between Yucatan and Quintana Roo (Dundee 1985). The realigned boundary was east of X-can, placing the village again in the State of Yucatan. With the advent of paved highways, constructed in the interim, X-can was conveniently accessible from the capital city of Merida. This was unacceptable to some of the residents of X-can, Yucatan, so they moved back across the territorial line and founded a new village, Pueblo Nuevo de X-can. X-can Nuevo lies at the junction of Mexican Highway 180, which runs from Merida to Puerto Juarez, and the highway south to Tulum.

The *Eumeces sumichrasti* that I reported (McCoy and Miller 1963) was collected at X-Can Nuevo, Quintana Roo. Hence the species should be removed from the Yucatan faunal list, where it would not be expected to occur on ecological grounds. The only record for Campeche (Velasco 1895) is unsupported by specimens, although the species surely occurs in the evergreen rainforest in the southern part of that state. X-can Nuevo remains the only known locality for the species in the northern Yucatan Peninsula (J. C. Lee, pers. comm.). Whether it represents a disjunct population, as mapped by Lee (1980:Fig. 20), cannot be determined without further collecting effort in the intervening area.

Smith (1992) also questioned the record of *Eumeces sumichrasti* from Xalapa, Veracruz (Boulenger 1887), as the species typically occurs in lowland forest habitats, usually below 300 m elevation. A specimen in the Carnegie Museum of Natural History (CM 43544) from Atoyac, Veracruz, ca. 500 m elevation, documents an inland occurrence in Veracruz. Undoubtedly the range of the species extends inland along river valleys, wherein tropical forest habitats penetrate the xeric uplands.

Field Observation of Predation on Bennett's Tree-kangaroo (*Dendrolagus bennettianus*) by an Amethystine Python (*Morelia amethistina*)

The amethystine python (*Morelia amethistina*) is found in Australia (North-east Queensland), the islands of Torres Strait and New Guinea. It is the largest member of the family Boidae in the region with specimens in excess of 8 m reported (Cogger 1992; Shine 1991). There have been no systematic field studies of this species. From museum and captive studies, as well as incidental field observations, it is alternatively reported to feed on a wide variety of vertebrates (Cogger 1992) or on mammals exclusively (Shine 1991). In a field study of Bennett's tree-kangaroo (*Dendrolagus bennettianus*), one individual amethystine python was potentially a significant predator of the study population and this communication reports the details of this predation.

Dendrolagus bennettianus is sexually size dimorphic, with adult male body mass up to 14 kg and females up to 10.5 kg, and the largest arboreal mammal found in Australia's tropical rainforests. It has an extremely restricted distribution, occurring only in the closed forests of an area of less than 4,000 km^2 between the Daintree River and Cooktown in Far North Queensland. The general biology of tree-kangaroos is poorly known and the main aim of this study (Martin 1992) was to investigate the diet and habitat requirements of *Dendrolagus bennettianus* which was regarded as a rare and possibly endangered species. The field study was conducted at Shipton's Flat (15°48', 145°14'), about 40 km south of Cooktown, in a 36 ha study area in lowland vineforest (240 m above sea level). This region is on the drier, northwestern fringe of Australia's major tropical rainforest belt and much of the closed forest here occurs in small patches, usually surrounded by open woodlands dominated by *Eucalyptus* species. For a more comprehensive description of the area see Martin (1992). In this area *Dendrolagus bennettianus* was found to be predominantly nocturnally active and to have a largely folivorous diet. Diurnally, it was extremely cryptic and spent most of the day sitting high up in the canopy, usually concealed in vines.

The first python kill of a study animal occurred during the night of 1 December 1990, sometime after 2200 h. The *D. bennettianus* killed, a juvenile female weighing 2.1 kg, had been captured and fitted with a radio collar 12 days earlier. It had been monitored from this time with its position and activity determined once every 12 h. On 2 December its radio signal was tracked to an engorged amethystine python lying under the dead foliage of a recently

fallen tree on the edge of the closed forest. A *Aidia racemosa*, a preferred food tree species of *D. bennettianus*, was nearby and its heavily scratched trunk indicated that it was being regularly visited by tree-kangaroos. In this area *D. bennettianus* are in the habit of moving each night from their daytime roosts, which are usually large trees towards the center of their home ranges, to feed in preferred food trees, many of which are located near the edge of the closed forest. Slip and Shine (1988) reported that the diamond python (*Morelia spilota spilota*) is an ambush predator that takes mammalian prey by sitting and waiting beside frequently used trails or, in the case of arboreal prey, in the forks of frequently used trees. *Morelia amethistina* probably hunts in a similar manner and this juvenile *D. bennettianus* was possibly taken either in or at the base of this *A. racemosa* feed tree.

The *M. amethistina* was 3.3 m in total length and had a mass of 10.5 kg. Sex was not determined. When closely examined it was found to have a recent, but partially healed laceration, approximately 150 mm long, across its throat. It looked like a rip from a claw, but it wasn't sufficiently fresh to have been inflicted by the juvenile tree-kangaroo. Subsequent events suggested that it may have been inflicted by the mother of this juvenile, who may have been killed by the same python.

Female *D. bennettianus* and their young usually remain together until the young are sub-adults in excess of 5 kg in body weight. Adult male *D. bennettianus* are predominantly solitary and usually only come into contact with juveniles when consorting with adult females. However, at the time the juvenile *D. bennettianus* was first captured it was accompanied by an adult male. It was too small to be independent and it was assumed that its mother had died. After its release the juvenile moved widely through the closed forest—presumably through its mother's former range (Fig. 1 shows the 95% isopleth of the harmonic mean home range). However, it did not reunite with an adult female. The failure of this juvenile to find its mother, the recent lacerations on the throat of the *M. amethistina*, and its location within the same area all combine to suggest that the mother may also have been killed by this python a few weeks earlier.

Morelia amethistina has a narrow pyloric sphincter and the radio-transmitter ingested with the juvenile tree-kangaroo remained lodged in the stomach of the python. This enabled me to locate it almost daily for 44 days, from 2 December 1990 until 15 January 1991 (Fig. 1). The snake divided its time about equally between the open and closed forest, with three periods of substantial inactivity. When active it moved between 109 and 348 m each day (mean = 190 m, SE = 73.6, N = 12). The day after it was first located the python moved a short distance (36 m)—possibly as a result of it being disturbed when it was handled for weighing and measuring. It remained substantially inactive for the following 8 days (2–9 December), either coiled on the ground or in the canopy. It then moved through the open forest for several days before becoming inactive under the base of a large dead tree for 9 days (17–26 December). During this time it may have been

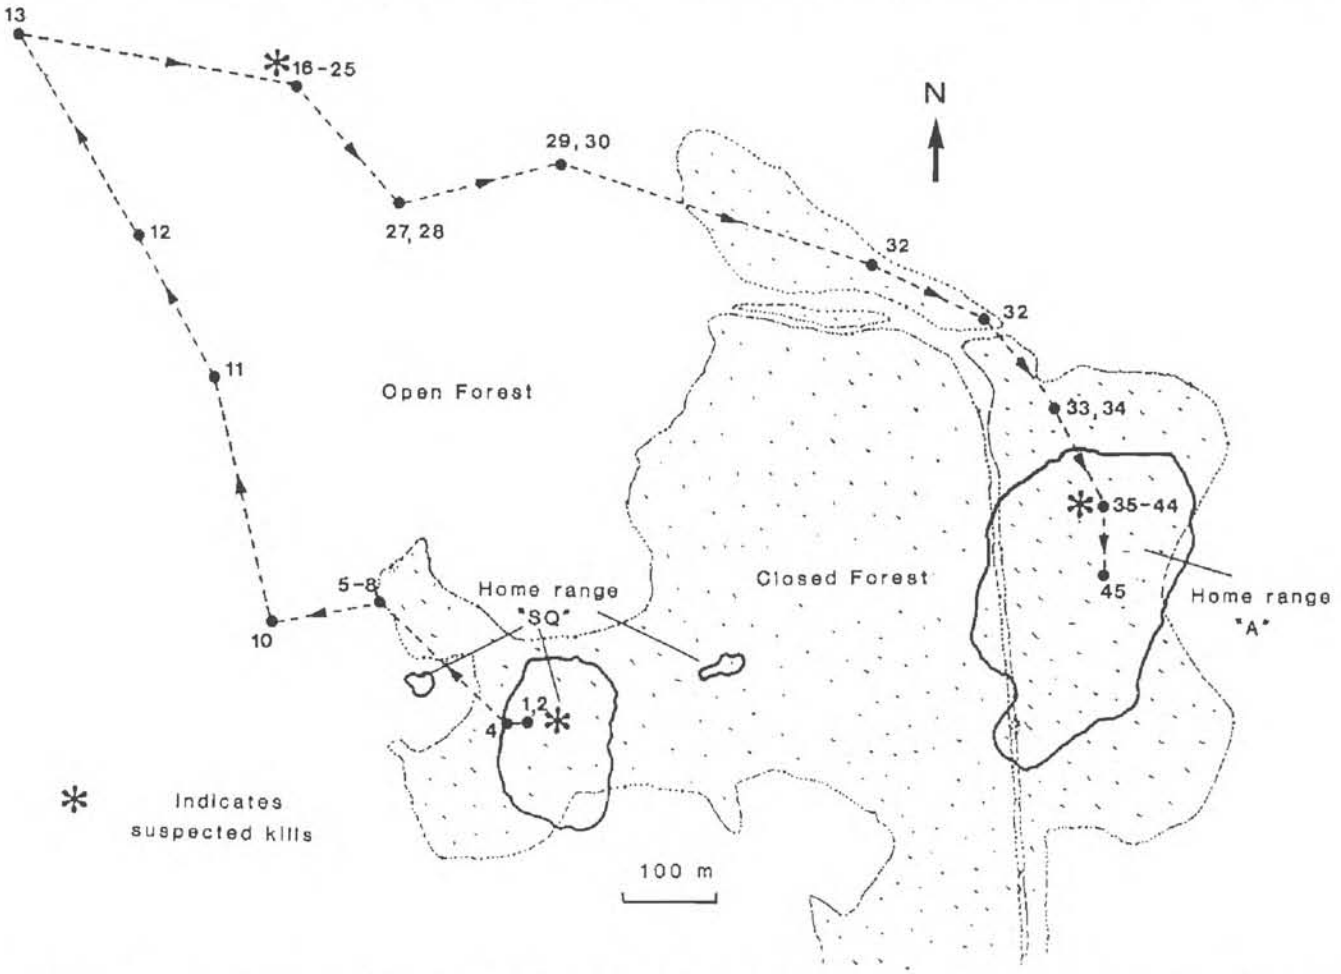

FIG. 1. Map of the study area showing the route of the python after it ingested the juvenile tree-kangaroo. The daily locations of the python are depicted as numbered points, the numbers indicating the days elapsed since it ingested the first tree-kangaroo ("Sq"). The heavy dashed line linking these points is the shortest distance between them and indicates the general direction of movement of the python but not its actual route. The area of closed forest is marked with light stippling. The boundaries of the home ranges areas (represented by the 95% isopleth of the harmonic mean) of the two tree-kangaroos taken ("Sq" and "A") are indicated by a solid line.

digesting prey it had taken in the open forest, but it was not possible to examine the python to confirm this. On 2 January it re-entered the closed forest, and by 5 January it had moved into the center of the home range of another radio-collared study animal—an adult female *D. bennettianus* accompanied by her juvenile male young (Fig. 1). This juvenile was not fitted with a radio collar. The *M. amethistina* remained in this location, inactive in the canopy, for 8 days (5–13 January). It could not be seen during this time, but its radio signal suggested that it was either in, or close by, a large specimen of *Castanospermum australe* that was frequently used as a daytime roost by the resident female tree-kangaroo and her young. This female and her young were not observed between 4 January and 8 January because of difficult weather conditions associated with an incoming cyclone. When last seen on 4 January the juvenile was still with the mother, but it was not seen again after this. It is conjectured that this animal was killed and eaten by the python on 5 January.

On 15 January the python was captured and held captive for several weeks until a veterinary surgeon could be found who would operate and remove the radio transmitter from its stomach. Some mammalian hair was found in the stomach during surgery, but most of it was caught up around the collar and possibly belonged to the first tree-kangaroo killed. After the stitches were removed and it had fully recovered and was feeding again, the python was released back into the wild.

While it has been reported that *M. amethistina* prefer mammalian prey (Shine 1991), smaller individuals are notorious predators of domestic poultry in this region and probably prey on all endotherms. Other mammalian species known to be taken by amethystine pythons in this area include agile wallabies (*Macropus agilis*), bandicoots (*Isodon macrourus* and *Perameles nasuta*), spectacled fruit bats (*Pteropus conspicillatus*) (C. Roberts, pers. comm. 1991) and common striped possums (*Dactylopsila trivigata*) (Handasyde and Martin, unpubl.). The *M. amethistina* monitored in this study possibly had a significant impact on tree-kangaroo recruitment. Of only four pouch-young known to be born in the study area during 1989-90, one was eaten and another suspected to have been eaten. In addition the mother of one of these juveniles also may have been killed by the same python. While the evidence is largely circumstantial, the observations suggest that large *M. amethistina* have the potential to have an impact on the abundance of tree-kangaroos in lowland rainforest.

Acknowledgments.—I thank Charlie Roberts and Tricia Handasyde for assistance with the fieldwork, Wendy Blanchard for her surgical skills in recovering the radio transmitter, and staff from the Queensland National Parks and Wildlife Service their post-operative care and release of the python back into the wild. I am grateful to Kath Handasyde for her comments on an early draft and to Gordon Schuett and Howard Reinert for the helpful suggestions they made in their reviewing of this paper.

POINTS OF VIEW

Parsimony

There is much to respond to in Pritchard's (1994) polemic entitled "Cladism: The Great Delusion." His treatment of parsimony is especially egregious, and I limit my remarks to that topic. Pritchard's (1994:105–6) criticisms are: (1) most parsimonious cladograms are unrealistic because they are always divergent—none shows lineage reticulation that might represent the formation of new species from interspecific hybridization; (2) the parsimony method does not take into account "prior knowledge" of the probability of homoplasy; (3) "good zoogeographic judgment" is not used as evidence; (4) independent evolution is so extensive in some groups (he cites Testudinidae) that a cladogram would collapse into an unresolved hypothesis of species relationships; (5) the use of parsimony in historical inference assumes independent evolution is rare. I answer these claims seriatim.

(1) It is true that cladograms are almost always presented as divergent hypotheses, because that pattern is sufficient to minimize hypotheses of homoplasy (convergence, parallelism and evolutionary reversal), except where necessary (see item 5b below). However, contrary to Pritchard's assertions, cladistic hypotheses can be reticulate, and cladists accept the notion of an interspecific hybrid origin of some species (e.g., Frost and Wright 1988; Humphries 1983; McDade 1990, 1992; Nelson 1983; Wanntorp 1983).

(2) The issue of "knowledge" of the probability of homoplasy can be taken into account by differential character weighting, either *a priori* or *a posteriori* (Farris 1969; Kluge and Farris 1969). In general, however, cladists tend to be cautious in making these kinds of knowledge claims because the empirical and theoretical justifications for them are often weak.

(3) That "good zoogeographic judgment" is not used as evidence is not a criticism of parsimony. Various classes of potential evidence are used in cladistic parsimony analyses, and the decision to exclude certain sources is defended on grounds other than having to do with parsimony (e.g., Kluge 1993; Kluge and Wolf 1993; see also item 5 below). For example, the age of origin of species, as might be inferred from the fossil record, is not employed ordinarily as evidence of phylogenetic relationships because temporal order could not then be used as an *independent* test of those relationships (Gauthier et al. 1988:188–190).

(4) The issue of homoplasious evolution being so extensive that it results in a completely polytomous most parsimonious hypothesis of relationships is an empirical question that can (and should) be looked at seriously. Indeed, if the Testudinidae cladogram is completely unresolved then one could conclude that parsimony has been useful in documenting that extraordinary case (see item 5e below). Until such research has been done we can only wonder about the evidentiary basis for Pritchard's assertion.

(5) According to Farris (1979, 1980a,b, 1982a,b, 1983, 1985, 1989:107; Farris and Kluge 1985, 1986), *in seeking the most parsimonious cladogram(s) for a data set of synapomorphies, requirements for ad hoc hypotheses of homoplasy are minimized, and it is on such a cladogram that explanatory power is maximized.* This justification for parsimony is widely accepted by cladists; however, important aspects of the arguments are often overlooked (e.g., Pritchard 1994), and I recount some of those details.

a. A cladogram by *itself* does not deductively imply the synapomorphic states of a character are homologous, even when

those shared-derived similarities are perfectly consistent with a hypothesized pattern of sister group relationships. A cladogram as a premise, and a consistent synapomorphy as a premise, does not lead necessarily to the conclusion of homology, because the two premises are not conjoined logically in that regard. Consider that a character with 110 distributed states does not have to be homologous even if cladogram (A,B)C is true.[1] Alternatively, however, a cladogram by *itself* does deductively imply homoplasy. To be convinced of this conclusion, consider character 011 in relation to cladogram (A,B)C. The observed distribution of state one in B and C can only be understood historically as independent evolution. Thus, one can see from this asymmetry in understanding why it is reasonable to bring parsimony to bear on the inference of homoplasy, but not on homology.[2] Of course, that a cladogram can deductively imply homoplasy does not mean that the phylogenetic hypothesis actually explains in some deeper evolutionary sense the basis for an inconsistent similarity—it only says that such a similarity is *coincidental* to (independent of) common ancestry.

b. Choosing the shortest length (most parsimonious—Kluge and Farris 1969) cladogram for a given data set, and using parsimony to optimize (minimize) the number of steps on that cladogram, are justified scientifically because explanations of homoplasy are understood to be *ad hoc*. *Ad hoc* hypotheses are to be avoided, because "[s]cience requires that choice among theories be decided by evidence, and the effect of an ad hoc hypothesis is precisely to dispose of an observation that otherwise would provide evidence against a theory. If such disposals were allowed freely, there could be no effective connection between theory and observation, and the concept of evidence would be meaningless" (Farris 1983:17). The *ad hoc* nature of homoplasy is of special concern in phylogenetic inference, because independent evolution can explain all manner of synapomorphy patterns, both those consistent and inconsistent with a cladogram (see 5a above).

c. As underscored above, the discovery of a cladistic hypothesis begins with minimizing requirements for *ad hoc* hypotheses of homoplasy for a given matrix of synapomorphies, and it concludes with explanatory power being maximized (Farris 1983:18). Generally in science, explanatory power is understood to be a function of *theory conforming to observation*, and in phylogenetic systematics the theory is inheritance and the observation is a novel trait shared by two or more groups of organisms. Thus, it is the most parsimonious cladogram that maximally explains shared-derived similarity as due to inheritance, i.e., synapomorphy as homology. Of course, providing such an explanation is no guarantee of accuracy, but then accuracy as it pertains to knowing the *truth* is not an obsession of cladists. Cladists focus on discovering the most rigorously tested and highly corroborated phylogenetic hypothesis, and that is why they seek the most parsimonious cladogram. Those who speculate on hypotheses of species relationships being more or less accurate do not employ parsimony in the sense of Farris (1983)—they judge their efforts according to the plausibility of the evolutionary models they employ in their determinations (Sober 1988).

d. Farris' explanatory power justification for parsimony has been criticized because some believe that it assumes homoplasies are rare in nature (e.g., Pritchard 1994). However, as Farris (1983:13; see also Sober 1988:136) countered long ago, the method of minimizing requirements for homoplasy does not necessarily presume minimality, i.e., rarity of homoplasy. As demonstrated with the example described above, neither hypothesis, (A,B)C or A(B,C), actually claims that homoplasies are rare—a cladogram places only a lower bound (but not an upper bound) on the number of homoplastic events required to explain the data. For example, it is possible to propose an even less parsimonious history for character 011 in relation to cladogram (A,B)C than the single independent origin of state one in B and in C—in fact there might have been indefinitely many such origins in just those two lineages.

e. Farris (1983) further assessed the sensitivity of parsimony to rarity of homoplasy with a more elaborate example. Consider three taxa, A, B and C, described by ten characters with the distribution 110 and one character with the distribution 011. Thus, parsimony requires that character 011 be interpreted as homoplasy in relation to cladogram (A,B)C, but the histories of the ten 110 characters may be judged an open question as regards homology or homoplasy. Alternatively, cladistic hypothesis A(B,C) requires that each of the 110 distributed characters be interpreted as homoplasy, while the 011 character is not interpreted as either homology or homoplasy. Farris (1983:13–14) then argued that if homoplasy were to be rare, it is quite likely that (A,B)C is the species genealogy, because in order for that hypothesis to be false, all ten 110 characters would have to be homoplasious.[3] Alternatively, homoplasy might be abundant, say to the extent that any ten of the eleven characters is homoplasious. In this context, Farris (1983:14) argued that if any one of the eleven characters is homologous, and that it is one of the 110 characters, then the (A,B)C cladogram is a much "better bet" than is the A(B,C) hypothesis. Thus, Farris concluded that as long as homoplasies are less than universal, there is no degree of homoplasy, by itself, sufficient to defend a less parsimonious cladogram over a more parsimonious pattern of sister group relationships. Of course, if homoplasies were to be universal, no inference methodology would be capable of recovering phylogeny.

The above comments cover only the most general aspects of parsimony, and only as they apply to cladistics. I strongly encourage the more philosophically/theoretically inclined readers of this journal to consult other sources on parsimony and the general subject of simplicity (see review by Kluge, 1984). Sober's (1993) short book on the "Philosophy Of Biology" has an excellent chapter on systematics, and his discussion of parsimony and likelihood is especially relevant. For the uninitiated empiricist, there are numerous herpetological examples to study, wherein cladistic methods are rigorously applied, including that of parsimony. One of the best studies that has come across my desk recently is by Crumly (1994), on the turtle genus *Gopherus*. It is a good model for the long overdue study on Testudinidae.

Acknowledgments.—David Cannatella, Alan de Queiroz, Darrel Frost, Jacques Gauthier, and an anonymous reviewer made several useful suggestions for the improvement of this paper, which I greatly appreciate.

[1] The parenthetic notation is meant to describe relative recency of common ancestry. For example, (A,B)C can be understood to mean that taxa A and B are more closely related to each other than either is to C. Two characters, with state distributions 110 and 011, are used to describe these three taxa. Character state 0 is assumed to be plesiomorphic, state 1 apomorphic (derived). Thus, the synapomorphy, shared-derived similarities, of the first character describes taxa A and B, whereas that of the second character describes B and C.

[2] The failure of induction to make such a distinction illustrates why that form of logic does not apply to phylogenetic inference.

[3] Given the assumption of character independence, the coincidental occurrence of homoplasy in all ten characters is taken to be very unlikely.

Phylogenetic Approaches to Classification and Nomenclature, and the History of Taxonomy (An Alternative Interpretation)

Herpetological Review has recently featured a series of papers debating the merits of recent developments in the theory and practice of systematic biology, using herpetological examples. In the latest and longest paper in this series, Pritchard (1994) passionately argued against many of these "cladistic" developments. Here I address three issues raised in his paper that bear directly on my own writings concerning systematic theory and practice. These are: 1) the abandonment of paraphyletic higher taxa, 2) the replacement of the current ("Linnean") system of biological nomenclature, and 3) the significance of these proposals in the context of taxonomic history. Contrary to Pritchard's implications, the proposals in question are not based on arbitrary or illogical cladistic dogma but on well-established evolutionary principles. Moreover, these proposals are not passing fads but manifestations of an important trend in the historical development of biological taxonomy.

Paraphyly.—Pritchard opposes the proposal that groups each consisting of a common ancestor and all of its descendants (monophyletic groups, clades) should be recognized as higher taxa, but that groups each consisting of a common ancestor and only some of its descendants (paraphyletic groups) should not. He argues in favor of recognizing paraphyletic higher taxa—for example, a Reptilia that does not include birds—on the grounds that first, they agree with commonsense vernacular concepts, and second, they are congruent with a particular model of speciation, which he illustrates using a human socioeconomic analogy. All of his arguments, however, overlook some important considerations.

Pritchard's first argument for recognizing paraphyletic higher taxa overlooks the fact that much of scientific progress has consisted of replacing commonsense vernacular concepts with concepts derived from corroborated scientific theories. A few examples of commonsense vernacular concepts that were widely accepted in previous times but have largely been replaced in the face of accumulating data are a flat earth, a geocentric universe, solid matter, fixed continents, immutable species, and a single taxon for both amphibians and reptiles. Evolution is often said to be the unifying theory of biology, and most biologists accept the proposition that taxonomy is to be based on evolution. A fundamental component of the principle of evolution is the proliferation of species from common ancestors. Therefore, equating higher taxa with groups of species sharing a unique and exclusive common ancestry constitutes an evolutionary concept of higher taxa (Hennig 1966). The lack of correspondence between these clades or monophyletic groups and commonsense vernacular concepts of taxa is a poor reason for retaining the latter, and it might even be considered resisting scientific progress.

Pritchard also favors the recognition of paraphyletic taxa based on a model of speciation in which an ancestral species remains unchanged while giving rise to a modified descendant species. He argues that the unmodified ancestral species deserves the same taxonomic designation before and after giving rise to the modified descendant, which deserves recognition as a separate taxon (thus rendering the ancestral species paraphyletic). Pritchard's argument suffers from implicitly extending to higher taxa a model that applies properly to species alone. That is to say, although there are accepted evolutionary processes through which species give rise to other species, there is no known evolutionary process through which higher taxa give rise to other higher taxa of the same or greater rank in the Linnean hierarchy (e.g., Wiley 1979). It is this inflated assignment of categorical ranks that results in paraphyly. For example, assigning both Amphisbaenia and Lacertilia to the rank of suborder renders Lacertilia paraphyletic because it implies that Amphisbaenia is entirely separate from Lacertilia rather than being a subgroup of that taxon. Categorical assignments are made by humans. Therefore, paraphyletic higher taxa owe their existence as much to the human mental process of assigning ranks as to any evolutionary process. Systematists who advocate the elimination of paraphyletic higher taxa do so because they wish to recognize as taxa only those entities resulting entirely from evolutionary processes.

Pritchard uses a sociological analogy to illustrate the supposed rationality of recognizing paraphyletic taxa and, at the same time, the supposed irrationality of cladistic practice. He describes a situation in which a lineage of peasants—let us call it the Bauer clan ("Bauer" is German for "peasant")—produces a daughter who becomes educated and gives rise to a lineage of urban professionals. He argues that cladists would insist nonsensically that the urban professionals be called peasants because they are descended from peasants. This characterization of the cladistic position is erroneous and results from Pritchard's failure to distinguish between socioeconomic classes and genealogical lineages (or more generally, between classes and systems, see de Queiroz 1988). Everyone who makes this distinction, including cladists, will classify the descendants of the educated daughter as urban professionals according to socioeconomic criteria, but they will also realize that the descendants' change in socioeconomic status does not remove them from the Bauer clan. An analogous distinction applies to taxonomy. Consider a situation in which a clade composed of insectivores ancestrally—Squamata, for example—produces a descendant lineage that enters a new adaptive zone and gives rise to a clade of herbivores. As long as a distinction is made between classes based on diet and monophyletic entities, there will be no problem classifying the modified descendants as herbivores while at the same time recognizing that they are part of the squamatan clade.

Nomenclatural Systems.—Pritchard also criticizes a recent proposal to replace the current system of biological nomenclature with one based on evolutionary principles (de Queiroz and Gauthier 1990, 1992, 1994). In his view, this as an example of "contortions forced on cladists by...their own arbitrary rules," which represents "iconoclasm that is unlikely to appeal to anyone except highly theoretical cladists" (p. 105). Furthermore, Pritchard implies that the current system promotes nomenclatural stability and that adoption of the proposed alternative would result in "total sacrifice" (p. 105) of that stability. Although adoption of a phylogenetic system of nomenclature would be radical in some important respects, it would not, contrary to the impression given by Pritchard, produce utter nomenclatural chaos. Indeed, adopting a phylogenetic approach to nomenclature would largely solve problems of nomenclatural ambiguity and instability caused by the current system.

Pritchard blames cladistic doctrine for problems stemming from the nonevolutionary nature of the current nomenclatural system, using recent proposals concerning the nomenclature of acrodontan lizards to illustrate his points. Frost and Etheridge (1989) proposed to unite the families Agamidae and Chamaeleonidae into a single family as a result of their conclusions concerning paraphyly of the family Agamidae. Because "Chamaeleonidae" is the older name in the family group, it becomes the name of the new family-level taxon. As a consequence, many species that were formerly members of the family Agamidae will now belong to the family Chamaeleonidae, and the group of species formerly rec-

ognized as the family Chamaeleonidae will either be left nameless or require a new name. Pritchard supposes incorrectly that this nomenclatural ambiguity and instability stems from the cladistic prescription against paraphyletic taxa. In this particular case, the proposal was indeed intended to eliminate a paraphyletic taxon. Nevertheless, the problem is more general in that it applies to all changes involving the taxonomic practices of lumping and splitting, regardless of motivation. Ironically, Pritchard's paper begins as a defense of an earlier paper by Lazell (1992) that included a proposal to unite the families Agamidae and Iguanidae. Although unification of these families was proposed entirely for traditional reasons, it would result in ambiguity and instability very similar to that generated by the cladistic proposal.

In contrast with the current system of nomenclature, a phylogenetic system would promote unambiguous and stable evolutionary meanings of taxon names. The central issue is the manner in which taxon names are defined. Under the current system, names are implicitly defined in terms of a nonevolutionary principle—the Linnean taxonomic categories. For example, the name "Chamaeleonidae" is defined under the current system as the family level taxon containing the type-genus *Chamaeleo*. This genus, however, is contained within each of several taxa in a nested series (i.e.,...Squamata: Iguania: Acrodonta: Chamaeleonidae: Chamaeleoninae: Chamaeleonini...). Consequently, any change regarding assignment of these taxa to the family category will result in a nomenclatural change (e.g., what was once Acrodonta becomes Chamaeleonidae). Under a phylogenetic system, taxon names would be defined in the explicitly evolutionary terms of ancestry and descent. For example, "Chamaeleonidae" might be defined as the most recent common ancestor of *Chamaeleo* and *Brookesia*, and its descendants. Under such a definition, Linnean categorical assignments are irrelevant, and thus the nomenclatural ambiguity and instability caused by changes in categorical assignment would be eliminated. Consequently, the name "Chamaeleonidae" would remain associated with the clade stemming from the most recent common ancestor of the same set of species that has traditionally been included in that taxon (see de Queiroz and Gauthier 1990, 1992, 1994 for further discussion).

Replacing the current system of nomenclature with a phylogenetic one, or as Pritchard puts it "dumping the Linnean system of nomenclature" (p. 105), would not be as disruptive as he makes it sound. Although the Linnean taxonomic categories would be eliminated, the taxa themselves and their existing names would be preserved. For example, I have already indicated that there would still be a taxon Chamaeleonidae made up of all of the same species; the only difference would be that it would be neither a family nor a member of any other Linnean category. The hierarchical component of taxonomy would also remain intact. That is to say, nested series of taxa such as...Reptilia: Squamata: Iguania: Acrodonta: Chamaeleonidae...and...Reptilia: Testudines: Cryptodira: Chelonioidea: Cheloniidae...would continue to be recognized. Although the assignment of taxa to Linnean categories is an old tradition, it is widely acknowledged that this is a highly subjective and artificial practice. In short, reformulating the nomenclatural system with an evolutionary basis would not only promote nomenclatural universality and stability, it would also preserve most of the structure of existing taxonomies, eliminating only their most questionable component.

The History of Taxonomy.—Pritchard views the developments described above as fads "that may well not survive the decade, let alone the centuries" (p. 105). He likens "the hurricane of cladism" to the "storm of pheneticism" with the hope that "this too shall pass" (p. 109). These characterizations and hopes or predictions fail to take into consideration the history of taxonomy, in particular, the changing role played by the principle of evolution. This history suggests both a very different interpretation of the significance of the developments in question as well as a very different prediction concerning their fate.

The idea that living things are related by common descent gained widespread acceptance over a relatively brief span of time during the latter half of the previous century. The influence of this idea on taxonomic theory and practice, however, was not nearly as pervasive or rapid. Historians and biologists have asserted repeatedly that the concept of evolution had little or no impact on taxonomy, but this generalization is oversimplified. The impact of the concept of evolution on taxonomy, though significant, has been difficult to perceive because several of its important manifestations occurred at different times long after initial acceptance of the concept itself.

Immediately after widespread acceptance of the idea that living things are related by common descent, many aspects of taxonomy became evolutionary in only a superficial sense. Specifically, evolution was granted the role of an after-the-fact justification or interpretation for previously existing taxonomic methods and concepts. Throughout the post-Darwinian history of taxonomy, evolution has been granted an increasingly important role in that discipline in that it has come to function, in one area after another, as a central principle or tenet from which fundamental taxonomic concepts and methods are deduced (de Queiroz 1988).

Various occurrences in the historical development of taxonomy are interpretable as manifestations of this trend. For example, during the middle of the present century, concepts of species in which the principle of evolution played a superficial role were replaced by concepts of species in which that principle played a central role. Specifically, concepts of species as groups of similar organisms were replaced by concepts of species as population lineages. This conceptual shift required the rejection of previously recognized species taxa that consisted of reproductively separate populations. For example, morphologically similar leopard frogs that were formerly considered members of a single species are now considered to make up several cryptic or sibling species (Hillis 1988). The same conceptual shift also required the acceptance of previously unrecognized species taxa for phenotypically distinct groups of organisms that nonetheless formed a single interbreeding population. For example, morphologically dissimilar striped and banded kingsnakes in southern California that were formerly considered separate species are now considered morphs of a single polymorphic species (Klauber 1944; Mayr 1944).

The prescription against paraphyletic higher taxa represents an analogous change. Concepts of higher taxa in which the principle of evolution plays a superficial role are being replaced by concepts of higher taxa in which that principle plays a central role. Specifically, concepts of higher taxa as groups of similar species are being replaced by concepts of higher taxa as clades, groups of species sharing an exclusive common ancestry. This conceptual shift necessitates rejection of previously recognized higher taxa that constitute only parts of clades, that is, paraphyletic higher taxa. The same shift also necessitates the recognition of previously unrecognized higher taxa for groups of dissimilar species that nonetheless form a clade. For example, morphologically dissimilar scaled and feathered amniotes that until recently have been recognized as separate higher taxa are now being considered to form a single higher taxon and one of its subtaxa.

The proposed change regarding the system of nomenclature would extend a central role for the principle of evolution into yet another aspect of biological taxonomy. Under this proposal, a nonevolutionary concept of how the names of biological taxa are defined would be replaced with an explicitly evolutionary one.

Specifically, definitions stated in terms of the Linnean taxonomic categories would be replaced by definitions stated in terms of ancestry and descent. This conceptual shift will necessitate abandoning the Linnean taxonomic categories, but it will also increase nomenclatural clarity, universality, and stability.

In conclusion, a consideration of the historical development of taxonomy suggests an interpretation of recent taxonomic events and proposals that differs significantly from the interpretation offered by Pritchard. Both the increasing abandonment of paraphyletic higher taxa and the proposal for a phylogenetic system of nomenclature do not represent passing fads; instead, they represent the most recent stages in a process that has been unfolding for more than 130 years. It is therefore unlikely that these proposals will be abandoned after a brief period of popularity. Moreover, if evolution is truly the unifying theory that many biologists believe it is, then resisting cladistic concepts of higher taxa and the development of a phylogenetic system of nomenclature will be detrimental not only to systematic herpetology but to all of biology.

Acknowledgments.—I thank David Cannatella, Darrel Frost, Kurt Schwenk, and two anonymous reviewers for comments on an earlier version of this paper.

Response to Peter Pritchard

I read Peter Pritchard's article (1994), "Cladism: The Great Delusion." with some dismay. Although I disagree with many of Pritchard's points, writing a concise response to his paper proved difficult because there is little in our respective philosophies of science that provides a common ground on which to begin any kind of fruitful discussion. Moreover, although Pritchard did note a few current controversies, these issues were largely lost among Pritchard's visceral responses to a number of indisputable facts: (1) cladists use concepts and words that are unfamiliar to some (and which sound inelegant to Pritchard); (2) cladists are critical people, serious about what they do (mean spirited, maybe even religious cultists, by Pritchard's lights), who have no special respect for tradition or those Pritchard considers to have the elevated social standing as luminaries; (3) because of their preoccupation with the nature and evaluation of evidence, cladists have no respect for the claims of special knowledge that Pritchard thinks are self-evident and which underlie his approach to science; (4) cladists, like other evolutionary biologists, frequently use computer programs to help them address complex problems (which renders their conclusions scientifically and ethically questionable according to Pritchard); (5) cladists use explicit methods (which Pritchard complains are difficult to learn); and (6) cladists, like other scientists, sometimes make mistakes (but unlike other scientists exemplify to Pritchard all that is wrong in modern comparative biology). Because all of these statements are true, albeit in a somewhat different light than viewed by Pritchard, they do not require responses, beyond noting that none have anything to do with scientific issues. I do suggest, however, that published criticism is effective at limiting sloppy science, at least when that criticism is not itself sloppy, and that the open exchange of ideas within the forum of critical discussion has made for more progress in comparative biology than any hagiographical appreciation of putative luminaries ever could. In effect, Pritchard has joined this tradition of criticism; he just missed his intended targets.

Rather than rehash technical issues that have been treated extensively in journals such as *Cladistics*, *Systematic Biology*, and *Evolution*, and write pages and pages that most would not want to read, I think the most profitable option is to present a brief reading list that should obviate the fears and objections which some readers may share with Pritchard. Because phylogenetics has come to dominate systematic theory and practice in the last 20 years, I would hope that most will want to understand why it has succeeded so well as a scientific program before they accept Pritchard's accusations at face value.

As a first introduction for herpetologists to what this controversy is all about, one should refer to Kurt Schwenk's (1994) recent article in *Herpetological Review*, a good (if unintended) rebuttal to many of the points in Pritchard's article, although I would not be honest if I said I agreed with everything Kurt has written in this paper. I do not know if Kurt thinks of himself as a cladist or not. Nevertheless, I am pretty sure that Kurt and I are still on speaking terms.

The logical and factual errors in Pritchard's assertions regarding the information content of organismal characters, ancestry of supraspecific groups, and parsimony, are numerous. To begin to understand the issues interested readers should read "Systematics," Chapter 6 in Elliott Sober's *Philosophy of Biology* (1988), a good introduction to the philosophy of phylogenetic inference. For a summary of common analytical procedures used by phylogeneticists, Wiley et al. (1991) is the best source. Just because Pritchard thinks that this Think-and-Do Book is too diffi-

cult (in the previous incarnation as Brooks et al. 1984, that Pritchard was aware of) is no reason for others to avoid learning what the various algorithms are designed to do and what their underlying justifications are.

Pritchard's beliefs about paleontology are difficult to assess because his points are *non sequitur* to phylogenetic inference, and perhaps have more to do with the fact that *the* major contributor to turtle systematics during the last 20 years, Eugene Gaffney, is a paleontologist *and* a cladist, with whom Pritchard obviously has some differences. Along these lines, several of Pritchard's comments on turtle anatomy may be warranted. Regardless, Pritchard's method of arguing from the specific to the general, generally referred to as induction, is the most widely *rejected* scientific approach (Popper, 1989), so Pritchard's specific criticisms may be less relevant than they appear at first blush. The now somewhat dated, but still very useful symposium volume *Phylogenetic Analysis and Paleontology* (Cracraft and Eldredge [eds.], 1977) would be a good place to start to understand the legitimate controversies in systematic paleontology, as would a reading of papers by Gauthier et al. (1988) and Norell and Novacek (1992a, b). Pritchard's inaccurate assertion that cladists do not use fossils may have something to do with an ongoing controversy regarding the character information provided by *necessarily* incomplete fossils (addressed by Gauthier et al. 1988), but in light of Pritchard's awareness of Gaffney's work with turtle fossils and phylogenetics over the last 20 years, one must wonder what would motivate Pritchard to claim something that is so untrue in turtles, a group with which Pritchard claims such authority.

To alleviate concerns that there is a monolithic cladistic mind police working to undermine right-thinking biologists, I would suggest reading David Hull's (1988) *Science as a Process*, even though this summary of the sociological and intellectual development of cladistics has been criticized for historic inaccuracies. A cursory glance at the conflicting position papers in either *Cladistics* or *Systematic Biology* should also allay concerns about a cladistic glitterati.

Pritchard is poorly informed about the recent literature on speciation and other topics in modern evolutionary biology and for those who do not want to make his same mistakes I suggest reading the contributions in Marc Ereshefsky's (ed.) (1992) *The Units of Evolution* and Sober's (ed.) (1984) *Conceptual Issues in Evolutionary Biology*. The anthology by Evelyn F. Keller and Elisabeth A. Lloyd (eds.) (1992) *Keywords in Evolutionary Biology* is a particularly useful summary of key concepts and definitions in evolutionary biology. Although Pritchard uses the term "adaptive radiation" for a large number of related similar species in an unresolved polytomy, the term actually refers to the putative similar patterns of convergent archetypal diversification found in diverse centers of origin (Osborn 1902).

I was confused how Pritchard would regard a fairly well-resolved cladogram that I published in 1992 as "absolutely useless," because before its publication workers believed that Brazilian *Tropidurus* lizards were more closely related to Galapagos "*Tropidurus*" than to former *Plica* and *Uracentron*, and now they do not. At several points in his article Pritchard thrashes cladists for making what he thinks are unwarranted knowledge claims and then he slams me for not making enough of them, apparently, although it is difficult for me to see the logic of his position. The implication of Pritchard's negative reaction to my published statement about lack of topological resolution (the number of unrejected cladograms) is that having large numbers of possible trees that are neither supported nor rejected by evidence tells something about cladists' inability to intuit **truth**. My narrow reaction to this part of his article was surprise that Pritchard could not distinguish between saying something and saying nothing. More broadly, it is clear from his comments that Pritchard thinks that it is better to proclaim oneself an authority and make up a story based on plausibilities and assumptions of imagined or poorly understood processes, rather than on explicit independent lines of evidence. Pritchard's approach is not strictly scientific, but, instead is leavened with romantic beliefs in the primacy of human intuition and the intellectual paternalism of self-professed authorities.

My first reaction on reading Pritchard's paper was *not* to respond—how could I, without having to write a textbook and without offending the many turtle hobbyists who value Pritchard's opinions? On second thought, it was clear that I had to respond *because* of Pritchard's relatively large following among the younger cohort of herpetology, just the people who may get serious about herpetology and who need to know early on that herpetology is science, and fundamentally about the open discussion of evidence and rigorous formulation of theories, not the *hubristic* just-so stories that Pritchard thinks of as science. Regardless of Pritchard's chafing at being held to a standard of evidence that restricts his story-telling, it is because cladistics has provided a framework for the rational discussion of evidence and scientific theories about evolutionary processes (e.g., adaptation, phylogeny, and biogeography) that it is now a standard component, in one form or another, in evolution, comparative anatomy, and herpetology textbooks (Duellman and Trueb 1986; Pough et al. 1989; Ridley 1993), and is beginning to impact heavily in studies of behavior, physiology, and ecology (e.g., Brooks and McLennan 1991; Garland and Adolph 1994; Garland and Carter 1994; Miles and Dunham 1993; Vitt and Pianka 1994). That there have been excesses and mistakes in both theory and practice in phylogenetic inference no one could deny; in this historical inference is identical to all other empirical sciences as well as evolutionary biology before the advent of cladistics. Like those of other empirical sciences, the discovery methods of phylogenetic inference will become more sophisticated with open discussion and hard work; systematics will never return to a golden age of luminaries that never was. Therefore, for Pritchard to argue that because errors and critical statements have been made by cladists means that the forum for the open evaluation of evidence and assumptions should be rejected in exchange for authoritarianism and just-so stories, simply represents antiscientific romanticism.

Cladistics: A Response to Pritchard

Scientific tools are not always received without controversy. The astronomer Tycho Brahe thought that using a telescope was cheating and assumed that they would go out of style. Pritchard (1994) similarly refuses what two generations of biologists are embracing as a great tool. Pritchard is determined to remain "unclad." I would simply point out that you can't get dressed until you know how.

In his recent discussion of cladistics (Pritchard 1994), it is clear from the outset that the author misunderstands his subject. Pritchard wants cladistics to be more than it is. It is not a totally new concept. It is not a new truth. It is a tool—a tool that allows biologists to evaluate evidence of a specific kind of relationship, recency of common ancestry or branching order. Because there can be only one correct branching order, the potential that we could recover that information and base a unified classification system on it should be very exciting to all biologists.

Cladistics, the attempt to reconstruct branching order among a set of terminal taxa using parsimony, has proven to be an invaluable tool for reconstructing the history of life. Consequently, it is having an important unifying effect on comparative biology (Brooks and McLennan 1991; Funk and Brooks 1990; Garland, and Carter 1994; Miles and Dunham 1993; Miyamoto and Cracraft 1993). Therefore, it is important that certain misunderstandings in Pritchard's contribution be addressed.

Phylogeny reconstruction and phylogenetic classification.—Pritchard (1994) misrepresents the positions of Gould and Mayr with regards to cladistics because he fails to recognize the utility of distinguishing the process of phylogeny reconstruction from the use of those reconstructions in classification. This important distinction was carefully pointed out in the pages of this journal very recently (Schwenk 1994). Pritchard (1994) wants us to believe that Gould and Mayr, like him, consider cladistics to be a great delusion. In fact, they are only opposed to the strict use of the results in classification. Ashlock (1979) summarized the view of the "evolutionary systematists" fifteen years ago by saying, "Cladists have made great contributions to systematic theory and methodology. Evolutionary systematists have, for the most part, accepted the analytical contribution of the cladists .... They object, however, to the automatic conversion of the cladogram into a classification." These views are repeated in Mayr and Ashlock (1991:234).

Gould (1989:38) embraces the concept of monophyly and elsewhere (Gould 1993:113) uses cladistic pattern observation in his discussion of the evolution of swim bladders from lungs. He states: "A reconstruction of vertebrate branching order gives a clear answer to this question." An earlier piece, "What, if anything is a zebra?" (Gould 1983), provides a summary of his views on cladistics. He calls cladistics "a formalization of procedures that good taxonomists followed intuitively but did not properly express in words, leading to endless quibbling and fuzziness of concepts." He adds that "...behind the names and nastiness lies an important set of principles." His major concern is that "some of our most common and comforting groups [like fish] no longer exist if classifications must be based on cladograms." Both Gould and Mayr apparently find the method conceptually sound and are only concerned about applying the results to classification (the need for which is discussed below). This is a far cry from Pritchard's implication that they find the cladistic method misleading.

Phylogenetic trees versus evolutionary trees.—It is important to recognize the difference between phylogenetic and evolutionary trees and to consider the relative testability of pattern versus

process hypotheses. Like many beginning students of phylogenetic systematics, Pritchard (1994) reads a cladogram as an evolutionary tree, from the bottom up. Cladograms are not evolutionary trees, they are schematic representations of recency of common ancestry. Because they are based on data derived from terminal taxa, they are constructed, in a sense, from the top down and should be read as sets within sets that share more and more inclusive branching events. Pritchard's desire to read cladograms as evolutionary trees leads to a long discussion of "missing links" that "would document the morphological evolution of life, ...by regular dichotomous splitting, to the taxa found today." He infers that cladists should expect to find representatives of all these nodes in the fossil record and points out that they are missing. But since the search for branching order does not require the recognition of ancestors, cladists do not search for, nor seek to identify, ancestors. Thus, they have made significant progress in spite of the well established problem that transitional forms are rare. Pritchard's mistaken view of cladistics prevents him from seeing the important fact that relative relatedness can be established even when there are large gaps in the record, or no fossil record at all.

Perhaps the most fundamental problem in Pritchard's approach to systematics is his reliance on untestable evolutionary scenarios. He fails to see the need for separation of pattern hypotheses from process hypotheses. By observing the results of evolution (pattern) a cladist attempts to reconstruct the relative recency of divergence of the groups of interest. Cladistic hypotheses can be tested by observing the features of the endpoints of evolution: fossil and living organisms. Pritchard's version of the "evolutionary" method frequently depends on hypotheses about the driving forces in specific evolutionary events. But it is extremely difficult, if not impossible, to scientifically test hypotheses about the causes of past evolutionary events. If we agree that a defining feature of science is testability, then classifications that rely on untestable process hypotheses are not science.

A specific example of Pritchard's attempt to use untestable process hypotheses (in this case to determine character polarity) is his suggestion that anyone who observes *Lepidochelys* using its shell to tamp down the sand over its nest might be convinced that the wide shell is an advanced feature for this behavior (Pritchard 1994:106). By pattern analysis, we can determine if the wide shell is primitive or derived for the genus, but it seems highly unlikely that we will ever know whether the wide shell originally evolved for nest-tamping or is secondarily used for this purpose.

Similarly, there is no way to test Pritchard's (1984) process hypothesis that the events which lead to a long neck in *Hydromedusa* are different from those which lead to a long neck in *Chelodina*. The pattern evidence in this case is ambiguous; morphological data suggests that these genera are sister taxa (Gaffney 1977), preliminary molecular results suggest that the South American and Australian chelids may each be monophyletic (Shaffer, pers. comm.).

Character selection in the cladistic and "evolutionary" schools.—It is also useful to reexamine Pritchard's claims about the types of characters and the degree of objectivity in the selection of characters that go into systematic studies. Pritchard (1994) reports that "evolutionary systematists" use all aspects of morphology and fossil history but use "judgment" to decide which are the "fundamental characters" and which are recent, plastic, or adaptive ones. He says "evolutionary systematists" emphasize the former and reject the latter. He would do systematics a great service if he could provide an explicit set of criteria for how one recognizes "fundamental" characters. His suggestion that systematists should reject adaptive characters means that we should not be using features such as the presence of vertebrae, four limbs, amnion, mammary glands, or for that matter, the turtle shell (all of which are highly adaptive) in our efforts to determine relationship!

The majority of practitioners in the cladistic school suggest that one cannot tell, a priori, which features will provide the phylogenetic message and which are noise. This information is available only after any message has been extracted. Choosing characters a priori suggests that one knows what the message should be. In dissecting out "fundamental features," the "evolutionary systematist" as described by Pritchard is being far less objective than the cladist.

However, Pritchard is correct in saying that cladists pick and choose their characters. Characters found in only one of the taxa of interest or all of the taxa of interest will not provide phylogenetic information and can be left out. Others may be found to be too variable within individual terminal taxa and are left out for that reason. But in every study with which I have been associated, any character that may shed light on relationships has been included.

Pritchard is inconsistent in his views about the data that should be considered in a systematic study. He (Pritchard 1994:103 bottom right) says that "traditional systematists ...[use] ...all aspects of the morphology ...," then on the next page he says they only use "fundamental" characters. Elsewhere he complains that cladists leave out undesirable characters, but then he is surprised to find a case in which I have used characters about which homology arguments may be questionable (i.e., reduction and loss of peripherals, and presence of an anterior hinge in kinosternids, carettochelyids, and trionychids; and presence of an intermaxillary foramen in staurotypines, carettochelyids, and trionychids) (Meylan 1987). These characters are, as Pritchard (1994) implies, best explained as independent occurrences in the Trionychia (Trionychidae and Carettochelyidae) and Kinosternidae (Meylan and Gaffney 1989). This determination of homoplasy is suggested by pattern evidence and not the untestable process hypotheses offered by Pritchard (1994). He tries to employ current structure and function to infer that these structures must have arisen from separate events—events that must have occurred at least 100 million years ago! I elected not to make this judgment a priori. The results of my first study of trionychoid relationships (including only living taxa) suggested that these features could best be explained as single events (Meylan 1987). A second study, which included new and important fossils (Meylan and Gaffney 1989), suggests that these features have occurred twice. This still does not make them "bogus" characters. For example, reduction (and loss) of peripherals within the epifamily Trionychoidae (along with paired ventral processes of the nuchal) suggests that the Cretaceous turtle, *Peltochelys* is the sister group of the Trionychia; reduction of peripherals within the Kinosternoidae (along with 9 other characters) suggests that the Kinosternidae is monophyletic (Meylan and Gaffney 1989; Meylan 1988).

In the work described above (Meylan and Gaffney 1989), 8 of 13 terminal taxa are extinct, and a major point of the paper is that inclusion of fossils overturns a set of relationships that were previously proposed on the basis of living taxa alone (Meylan 1987). In the paper from which Pritchard extracts a specific example for his argument that cladists ignore fossils (Gaffney and Meylan 1988), 55 of 144 included genera are extinct. Looking through a stack of Gaffney's papers I find that nearly every one includes data from extinct forms. So, Pritchard's claim that cladism ignores the fossil record seems preposterous based on the literature that he should know best.

The meaning of relationship.—In order for systematics to be scientifically useful, the concept of relationship needs to be uniformly applied. Since Pritchard seems intent on using a priori selection of "fundamental features" and an established strategy of "apocryphal stories" (see Brooks 1990) to determine relationships among turtles, it may not matter that he is also willing to allow "relationship" to mean different things to different workers. But this poor state of affairs is illustrated by his defense of a paraphyletic Agamidae. The realization that this family is paraphyletic with respect to the Chamaeleonidae means that it is the herpetological equivalent of my car and three geese. "Agamids" may be "more similar," but similarity is a poor criterion for classification. Like beauty, similarity is in the eye of the beholder. Thus, to some observers my car and three geese may be the most similar items in a set under consideration.

Given a single group to study, a morphologist, behaviorist, and two or more geneticists working with different genes might see different subsets in that group as being "most similar" and they might suggest four or more classifications, each acceptable under the "similarity" model. But all of these data could be interpreted in a cladistic framework, and if they were, the independent analyses would at least be aimed at finding the same single correct answer that reflected the one history of life. If every classification sought to reflect the one correct history of life, then at least there would be only one, and not many, correct classifications. It simply won't do to have multiple possible correct classifications. That is what we get if we continue to recognize non-monophyletic groups.

In closing, I would suggest a test of Pritchard's assertion of the lack of utility of the cladistic method. Look through the literature on turtle systematics for the past 50 years. Compare the contributions to systematics and classification made by the various schools. You will see that cladistics has proven to be an excellent tool for turtle systematics.

Acknowledgments.—I have benefitted from discussions of Pritchard's paper with Henry Mushinsky's herpetology discussion group at USF. I thank Darrel Frost, Gene Gaffney, John Iverson, Anne Meylan, Dawn Wilson, and especially Brad Shaffer for their comments on this reply. Support for research of issues in turtle systematics has been provided by NSF grant DEB 9306633.

Human Nature, Science, and the Anonymous Peer Review System: Responses to Burke and Pisani

When we published our paper on the anonymous peer review system (Wilson and McCranie 1993), we wished to stimulate comments and, ultimately, change in an obstructionist and counterproductive set of procedures. Thus, we are pleased that Pisani (1994) and Burke (1994) responded. We mostly agree with Pisani, but see below. However, we disagree with Burke. At issue is the ability of science (in particular, herpetology) to survive the impact of the ethics of convenience and lowered professional expectations. Apparently, Burke and to a lesser degree Pisani act as apologists for these developments, citing the purported exigencies of "human nature."

Pisani (1994) opined that lack of editorial conscientiousness arises because "... editors, like other scientists, are human first and scientists/editors second, with all the room for ego abuse and lack of character that implies." We maintain that falling back on the old saw that "one cannot change human nature" is to attempt to excuse human frailties by resorting to folklore and that scientists are held to a higher standard. Although Pisani's suggestion that a "totally" anonymous peer review system, under discussion by KU's mammalogists, is "interesting," it is by no means "logical." First, a system in which "the author is unknown to the reviewer, who remains anonymous to the author" is not *totally* anonymous. After all, the identity of both is known to the editor (a *totally* anonymous system, in which no one is known to anyone else is an oxymoron; a system is a collection of *interrelated* parts). In addition, given the contact among herpetological colleagues working in the same area of research, it is unlikely that such a system would really keep identities of author and reviewer unknown to one another. Furthermore, authors frequently build on their past work and therefore cite themselves often. This type of system would be prone to greater abuse than the one we currently use, allowing both reviewer and author to operate in secrecy, increasing the chances for animosity among colleagues to arise. Finally, it would move the peer review process further from the cooperative atmosphere supposed to exist in science and further toward obeisance to the whims of "human nature." We believe that neither end is desirable nor defensible.

We reserve our strongest objections, however, to Burke's (1994) ideas, for it is therein that we find a logically inconsistent use of the term "human nature" and a seriously ill-informed view about the workings of science. Burke's response is carefully constructed, clearly written, and indisputable through the first four paragraphs. From that point onward, however, his argument is disarmingly confused.

Burke's first major point is that, "All systems are prone to abuses, and Wilson and McCranie are right to point out the need for periodic evaluation of the status quo." Whereas it may be correct to say that all systems are prone to abuse, we must do more than simply "evaluate the status quo." The nature of the scientific process requires us to expose and rectify such abuses to the system of science, because their continuance erodes its foundation.

Burke (1994) also believes our critique "... underestimates the effect onymity would have on the objective nature of our field." In defense of this view, Burke confusingly discussed the "... inherent conflict that we all face between subjective human nature and the objective nature of science." He noted that it has been his experience that "... anonymity dulls subjectivity and enhances objectivity." This is because he is acquainted with many of the authors whose papers he reviews. Consequently, he has "... made every effort to divorce [his] relationship from [his] evaluation of their work. Knowing that [he] would remain anonymous to the authors' greatly enhanced [his] ability to approach objectivity (consciously and presumably subconsciously)."

In his use of the term "human nature," Burke implies that there are certain features of human behavior over which we have little or no control. We interpret this to mean that these features are not subject to modification by life experience (i.e., learning); in other words, they are instinctive. Since notions of objectivity and subjectivity are outgrowths of human rationality and concepts that must be learned, using the term "human nature" in the context Burke does is specious and introduces a "red herring" into the dialogue. Thus, Burke maintained that "human nature" (in his sense) is "subjective," whereas "science" is not, and that movement from a subjective to an objective stance by a reviewer is facilitated by remaining "unknown" to the author. To say that "human nature" (in Burke's usage) is "subjective" is virtually redundant, since the word subjective means "proceeding from or taking place within an individual's mind such as to be unaffected by the external world" (American Heritage Dictionary, first edition). On the other hand, the word objective means "of or having to do with a material object as distinguished from a mental concept" (American Heritage Dictionary, first edition). Since science seeks to create a set of concepts to theoretically explain natural phenomena, it cannot be truly objective in the above-indicated sense of this word. Even giving Burke the benefit of the doubt and allowing that he considered objectivity to be synonymous with impartiality (some usages of the former come close to the usage of the latter), he maintained that such lack of prejudice or bias is enhanced by hiding one's identity. Such a position is interesting, if illogical, and would seem to mean, for instance, that members of the Ku Klux Klan wear hoods to show their lack of racial prejudice. Such a point of view is ludicrous. Objectivity or impartiality does not depend on anonymity, it depends on the reverse, an open acknowledgment of one's ability to stand up for one's opinions and conclusions. Beyond all this and of greater importance, onymity may have less effect on objectivity than on whether the review is constructive or destructive. Signing reviews has the value of encouraging constructive criticism on the part of the reviewer.

Burke's second major point is that we limited our discussion "to the effects of anonymous peer review on the scientific community." He stated that "... most scientists have patrons (e.g., granting agencies, private foundations, industry, taxpayers) and research results often impact those patrons." Furthermore, he noted that, "Because our results don't only impact us, it is important that persons outside our community have confidence in the integrity of our system of checks and balances." Burke's view appears to depend on the confusion of the *anonymous peer review system in particular* with the *peer review system in general*. The peer review system exists in order to best assure that what is published is as original, substantive, accurate, and defensible as it is possible for us to make it. Reviewer anonymity is not a prerequisite for such an outcome. *Both* authors *and* reviewers are held to draw conclusions that will stand up to scrutiny. Burke also maintains that allowing scientists to operate behind the cloak of anonymity will inspire confidence in people outside the scientific community "... in the integrity of our system of checks and balances." We confess to being nonplused as to how scientists operating in secret can inspire confidence in anyone about anything, especially our purported "integrity." Finally, Burke attempted to underscore the importance of his view by noting that a paper he recently published on the diet of sea turtles in New York waters "... will presumably be the basis for decisions

regarding habitat protection in New York." He maintained that, "The publication of [his] study following rigorous peer review by persons unknown to [him] can only strengthen its credibility and therefore its value to [his] patron, the New York State Department of Environmental Conservation." The question we ask of Burke is how and why the acknowledgment of reviewers' names during the peer review process is going to *undermine* the credibility of the study or its value to his patron. Let us put it another way. Let us say, for example, that Burke's study is sent to Randy McCranie or Larry Wilson for review. Because of their ethical position, stated in print, the one conducting the review signs his name to it. How will the acknowledgment of the name damage the credibility and value of Burke's study? Why is not the reverse the case? Why would not an honest review from one of these "established" researchers (to use Burke's language) not enhance the credibility of his study and its value to his patron?

Although we appreciate both the Burke and Pisani responses to our critique, we find ourselves at odds with their analyses, especially that of the former. Burke appears ready to jettison the need for absolute honesty in the sciences to allow for a timorous retreat behind the curtain of anonymity in order to inspire confidence in people who fund his research. This appears to us to be a particularly heinous brand of situational ethics giving rise to an unconscionable lowering of our professional expectations. The peer review system is supposed to allow substantive critiquing of one's work by his peers. Peers are those who have equal standing with oneself. We would find it difficult to accept as peers those who do not have the courage of their convictions sufficient to allow themselves to sign their own work.

In apologizing for such cowardly behavior on the part of the reviewer, Burke and Pisani appear willing to concede to editors more power in shaping the direction of herpetological research than we think they should have. This is because of the potential for sheltering destructive reviewers in anonymity in what is supposed to be an open, aboveboard, rigorous, and cooperative undertaking. We believe an onymous system would allow reviewers *and* editors to be held much more accountable for their editorial decisions. Burke and Pisani miss this point when they recount their generally productive experiences with journal editors as support for their views. Our experiences with editors usually have been similar. The point is that even though they may use their power wisely, they should not have the kind of power they do with the anonymous peer review system in a discipline utterly dependent on free and open discourse. Let us allow ego-driven, but cowardly reviewers to seek the psychological counseling they apparently need and discontinue maintaining a system that indulges them.

Lest we be accused of placing too much emphasis on the ill that a few reviewers operating behind the "iron curtain" of anonymity can commit, we wish to reiterate and emphasize that science depends on absolute openness and honesty (Sigma Xi 1986). Although the Sigma Xi document is primarily concerned with fraud in science, it does quote C. P. Snow to the effect that, "The only ethical principle which has made sciences possible is that the truth shall be told all the time." Fraud is a "deception deliberately practiced in order to secure unfair or unlawful gain" (American Heritage Dictionary, first edition). Hiding one's identify as an anonymous reviewer is also a form of deception not far removed from fraud. As such, its continued existence, like that of its uglier cousin, fraud, will unduly erode the openness and honesty vital to science.

Acknowledgments.—We thank John A. Jones and Richard D. Howard for their comments on this manuscript.

Tail Waves, Eye Licks, Vocalizations, and Priorities

In systematics, "priority" is respected as much as it is in the history of technology. But in other fields of herpetology (e.g., behavior, morphology) papers too often claim priority for the observation of phenomena which in fact had been published long before. Most commonly this happens out of ignorance of the earlier work. Many authors do not exploit literature published in other languages and some—that published in other countries. I narrate here a couple of choice examples and propose a partial remedy.

A recent statement in *Herpetological Review* claimed that "this is the first record of tail waving behavior as part of a prey capture tactic in gekkonid lizards." The statement was made by Perez-Mellado (1994), who in the preceding paragraph described how *Tarentola mauritanica*, on Minorca (Balearic Islands), approached relatively large prey: "The lizards raised their tails during the slow approach, moving it laterally and sometimes with the distal portion of the tail slightly brought forward. The final charge was accompanied by increased vibration, shaking rapidly the tip of the tail."

Described or not, waving and vibrating the tail while stalking the prey are quite common among geckos. *Gekko hokuensis*, one of three species observed by Werner et al. (submitted), frequently showed these behaviors while foraging and stalking. In this case these tail movements were mainly seen during the brief pauses that this species makes in its intermittent advance.

Admittedly, it could have been that, just because of its commonness, this gekkonine behavior had not been reported earlier. Let me illustrate this point: Although Aristotele (4th century BC) had mentioned the voices of "oviparous quadrupeds," by the time I visited New Zealand in 1970, no vocalizations had been reported from the local skinks. When my hosts of the N.Z. Ecology Division (Tony Whitaker and Bruce Thomas) and I caught a skink and it cheeped (Frankenberg and Werner 1992; Werner 1973), and I expressed surprise, they said, "Yes, skinks squeak when caught." When I protested, "But none of you has ever reported this!" they said, "What is there to write about? Skinks just squeak when picked up."

But, as it happens, the gecko's rear end fared differently. Mertens (1946), in his classic monograph, explained that aposematic behaviors are expressions of excitement, which need not necessarily be caused by an enemy or a rival; rather, it can just as

well be aroused by a mate or a prey animal. Mertens continued (I translate), "Hence one sees, for example, some geckos, such as *Tropiocolotes steudneri* or *Ptychozoon kuhli*, performing with their tails the same undulating or waving motions, during the suspicious, tense, crawling upon an insect, as when meeting another lizard or else a larger creature."

Such oversight of earlier behavioral observations happens readily and is quite frequent. Skipping cases of personal bias, I revert to the gecko's head for a by now historical last example. No lesser a person than Hobart Smith (1952) described a gecko, *Sphaerodactylus notatus*, often licking the lips and wiping the lidless eye with its tongue. Smith concludes, "Whether it is a habit restricted to this genus or of general occurrence in geckos with immobile lids remains to be determined, inasmuch as no similar observations have, to my knowledge, been noted previously for any species." Later, Mitchell (1958) seemed to regard the eye wiping behavior of geckos as a local Australian discovery whereas Bustard (1963) credited Smith (1952) with this discovery.

But Smith's modest caution had been well placed. Already F. Werner (1913:9) had described eye-licking as a family trait of the Gekkonidae (I translate): "The tongue is wide, flat, a little notched at the tip. As a rule, it is extended only in drinking and in eating, as well as in cleaning the eye. In this it is extruded from the mouth sideways and extended so that it can completely lick the eye." Perhaps in Werner's wake, Aharoni (1929:63) described eye cleaning in *Ptyodactylus*.

In conclusion I propose that editors of herpetological journals would do well to be wary of manuscripts in which the Literature Cited is bound within the ghetto of any single language. This is true in general but applies in particular to such fields as morphology or behavior.

To Stipple or Not to Stipple

Range maps are one of the most important features of any field or identification guide to reptiles and amphibians or other organisms. These maps can be extraordinarily useful and often stimulate other workers to explore areas of uncertainty that are disclosed. However, range maps appear in about as many formats as there are guides and authors, and thus are of variable usefulness.

The mapping style chosen is partially dependent on the purpose of the map and the portion of a particular publication that can be devoted to maps. Publications such as Conant and Collins (1991) do not detail individual locality records but use stippling in various ways to denote geographic ranges. This is appropriate when the geographic extent of the ranges included is large and the space allotted to map them is small. Regional or state field guides (e.g., Smith 1961; Minton 1972) detail individual locations with symbols. Some authors (e.g., Johnson 1987) mark each county with a symbol in the center of the county. Others (e.g., Smith 1961; Minton 1972), are more specific and place symbols at locations in each county for all specimens examined or previously reported in the literature. Many authors (e.g., for the *Catalogue of American Amphibians and Reptiles* accounts) also stipple their maps even when specific records are detailed. The purpose of this paper is to criticize the practice of stippling range maps that mark individual localities with symbols, but not to reopen an earlier discussion on range map accuracy (Axtell 1983, 1987; Blem 1987a, b).

Rather than provide a lengthy list of examples from regional field guides or from *Catalogue* accounts, I will cite a single example drawn from Smith (1961). I chose this work because it is, in my opinion, one of the best regional field guides ever published. Although it has been in print for over 30 years, without revision or updating, it is still a highly useful work for students of Illinois herpetology. The particular example I have chosen, the range map for *Clonophis kirtlandii*, was selected because it typifies a species whose limited range is poorly known.

Among the many regional field guides and *Catalogue* accounts I have examined, stippling is used for one of two purposes. First, it is used to show areas of intergradation between subspecies by utilizing differing shading styles for the various taxa involved. This usage, when based on examination of specimens, communicates objective information.

The second purpose is to indicate the presumed range of the species by including areas from which the species has not been collected. If the stippling includes such areas, then it is speculation by the mapper that the taxon occurs there. This speculation can be considered a hypothesis. Such hypotheses can be tested by field searches of the area in question. However, such a hypothesis can only be verified; it cannot be falsified. Even if the area is searched and no specimens are found, the hypothesis cannot be falsified because it is always possible that the species was missed.

Published speculations of distributions using range map stippling can have unfortunate results. Stippled range maps tend to validate a hypothetical distribution. Even though the speculative nature of the map is pointed out by the original mapper, such maps are frequently uncritically accepted by subsequent workers. If the organism happens to be endangered or threatened (as is *C. kirtlandii*), then uncritical acceptance of speculative range maps can have important political and economic consequences.

I have redrawn the stippled portion of the range map for *C. kirtlandii* (Fig. 1a, from Smith, p. 253). This map reflects Smith's apparent belief that this snake also occurs in all or parts of Kankakee, Iroquois, Ford, Livingston, Moultrie, and Edgar

counties (portions of Illinois east and north of the Shelbyville moraine), although no specimens or published records existed when the map was prepared. Rossman and Powell (1985) also stippled these counties even though no specimens had been reported in the intervening 24 years.

Since publication of Smith (1961), Tucker (1977) and Bavetz (1994) have addressed variation and distribution in *C. kirtlandii*. I (Tucker 1977) noted that no specimens had been discovered in the first four mentioned counties (see above) and questioned whether or not the snake occurred there. Bavetz (1994) noted that the same four counties still had no documented populations. He also noted that this particular area had been covered by post-glacial lake beds. We both had observed that samples from the northern counties of Illinois were slightly differentiated meristically from samples collected in central Illinois.

The documented localities of *C. kirtlandii* are plotted (Fig. 1b) along with the location of these post-glacial lakes from Willman and Frye (1970, Fig. 9). The virtual absence of overlap between localities for *C. kirtlandii* and the former location of the glacial lakes is evident. Although the documented range of *C. kirtlandii* has been considerably extended (Rossman and Powell 1985), no specimens have been reported in the portion of Illinois containing these post-glacial features. This suspected hiatus in the range of the species is consistent with the very slight morphological differentiation that Tucker (1977) and Bavetz (1994) noted.

Had Smith (1961) or Rossman and Powell (1985) published their maps for *C. kirtlandii* without stippling, this apparent hiatus in the range would have been much more obvious. More interest in investigating this gap might have been generated among herpetologists.

In this instance, use of stippling was not only speculative but possibly inhibited subsequent investigation of the species in this area. At present no investigator has looked at the distribution of Illinois reptiles and amphibians in relation to these post-glacial features. Examination of Smith's maps shows a paucity or absence of records in this region for several widely distributed species. These species include *Ambystoma maculatum*, *A. tigrinum*, *Plethodon cinereus*, *Necturus maculosus*, *Bufo woodhousii fowleri*, *Pseudacris crucifer*, *P. triseriata triseriata*, *Rana catesbeiana*, *R. sylvatica*, *Elaphe obsoleta obsoleta*, *Storeria occipitomaculata*, *Regina grahami*, *R. septemvittata*, and *Sisturus catenatus*. All of these species, like *C. kirtlandii*, have been found both north and south of the area in which Pleistocene lake sediments occur in Illinois, but no or few localities are known from within the area occupied by these sediments. Other glacial features such as the Shelbyville morainal system (Smith 1961) are also known to be correlated with distributions of reptiles and amphibians in Illinois. It is possible that the absence of records for many of these species may reflect the likelihood that common species are ignored by collectors and less likely to be preserved, deposited in institutional collections, or reported in the literature. But this cannot be said for less common species such as *C. kirtlandii* and *Sisturus catenatus*.

Therefore, stippling of range maps with localities marked by symbols in regional field guides or in the *Catalogue* should be avoided or discontinued except where it is used to denote areas of intergradation between adjacent subspecies. Speculations on distribution should be placed in the text rather than on the maps.

Acknowledgments.—I thank M. Bavetz for sharing information from his thesis with me. R. W. Axtell's and J. T. Collins' criticisms of the manuscript are much appreciated.

TECHNIQUES

A Simple Aquatic Funnel Trap and its Application to Wetland Amphibian Monitoring

Techniques for monitoring adult amphibians at breeding sites are described by Scott and Woodward (1994) and Dodd and Scott (1994). Quantitative sampling techniques for larvae are reviewed by Shaffer et al. (1994). In these reviews, aquatic funnel trapping was bypassed as a method for monitoring adults but recommended as a tool for estimating species richness and relative abundance of larvae.

In unpublished studies, I used large, bulky, and expensive wire mesh funnel traps (e.g., minnow traps) to determine palustrine wetland use by adult *Pseudacris regilla*, *Taricha granulosa* and *Ambystoma gracile*, and stream use by larval *Dicamptodon tenebrosus*. I baited traps with plain or shrimp oil dipped salmon eggs (Pautski's Balls of Fire) in a perforated 35 mm film canister to increase the capture rate of amphibians. Calef (1973) used a trap made by fastening an insect screen funnel into a 3.5 liter (1 gallon) plastic jug to capture tadpoles of *Rana aurora*. Calef, however, provided no other details such as jug diameter or specific mode of application. Whitman (1974, cited in Riley and Bookhout 1990) used a plastic aquatic funnel trap to capture macroinvertebrates. Riley and Bookhout (1990) altered Whitman's trap to monitor invertebrate activity in the water column. The adapted trap is constructed by stapling top and bottom ends from two 2-L plastic beverage bottles together.

The absence of explicit design characteristics for amphibian funnel traps in the herpetological literature (Dodd and Scott 1994; Scott and Woodward 1994; Shaffer et al. 1994), my successful amphibian census experiences with minnow traps, and the publication of Riley and Bookhout's (1990) inexpensive and easily constructed invertebrate funnel trap prompted me to investigate the potential merits of Riley and Bookhout's trap in amphibian censusing. I describe here the details of trap materials and construction, with modifications that have enabled me to use it successfully for wetland amphibian censusing under diverse habitat conditions without adult and larval mortality.

Materials and Construction.—Each funnel trap set-up requires two clean, clear plastic, 2-L soda-pop bottles, three 0.32 cm (1/8 inch) diameter aluminum rivets with a 0.48 - 0.63 cm (3/16-1/4 inch) grip range, three 0.32 cm (1/8) inch) diameter aluminum washer plates, three plastic clothespins, and one 0.79 cm (5/16 inch) or slightly thicker stainless steel rod of length determined by water depths to be sampled.

Using a razor blade I cut an initial slit near the top of one bottle approximately 0.3 cm below the end of the neck taper within the bottle's midsection. I separate the top by continuing the cut with scissors around the bottle. I similarly cut the bottom from the second bottle with a cut 0.3 cm beyond the seam at the base but again within the midsection of the bottle. The top ends of both bottles are saved. Next I use a hot nail to burn four 0.32 cm holes into the larger section and into the clothespins. I burn one air/water exchange hole 0.3 cm below the bottle's taper within the midsection, and three rivet holes in a straight line at 4, 9, and 14 cm from the bottom along the opposite side. I also clip roughly 1/4 of the plastic from one handle of each clothespin and then burn a 0.32 cm hole into the center tip section of each unclipped end. I then rivet a clothespin through the handle to each hole in the bottles' midsection. Finally, I reverse the short tapered funnel end and slide it within the bottom of the main bottle forming a tight, escape-proof fit and overlapping lip for stapling (Fig. 1).

Applications.—I have attached up to three traps along one stainless steel rod to simultaneously measure captures in 2 m of water at several depths within the water column. In deep water I position traps vertically with funnel side down. This maintains the required air pocket within the top so captured amphibians don't suffocate. In shallow water I drive rods with attached traps diagonally in the water, again making certain to provide air pockets. Water-filled traps not fastened to rods sink and will kill captured amphibians. Although heavier than aluminum, I use stainless steel rods because they do not corrode and therefore, minimize water quality impacts. I also bait traps with 5-10 salmon eggs but have never tested trapping success between baited and unbaited traps, nor between shrimp and non shrimp oil dipped eggs.

I found my funnel trap set-up invaluable in determining spring arrival times of breeding *Ambystoma macrodactylum*, *Ambystoma gracile*, *Taricha granulosa*, *Rana aurora* and *Pseudacris regilla*. Leonard and Richter (1994) have successfully combined several months of aquatic funnel trapping with mark-recapture statistics to census adult *Ambystoma macrodactylum* populations in a small breeding pond. At some wetlands these aquatic funnel traps captured adult amphibians that were not previously detected by visual searches, dipnetting, or pitfall trapping.

Funnel traps also enabled me to describe the spatial and temporal microhabitat use by larval *Ambystoma gracile* and *Rana aurora* (Richter, in prep.). I have captured larvae using these traps with minimal habitat disturbance, by simultaneously trapping in yellow water-lily (*Nuphar polysepalum*), cattail (*Typha latifolia*), and soft rush (*Juncus effusus*) dominated emergent plant communities and in open water areas of varied depths, over 8-hour day, 8-hour night, and during 48-hour trapping periods without mortality. Karlstrom (pers. comm.) used these traps successfully in 1994 to

TECHNIQUES

Descriptions of methods, materials, study sites, etc., should be sufficiently detailed to permit an assessment of the utility of the technique or equipment for other areas or taxa. Manuscripts should be sent directly to the section editor: *Stephen D. Busack, National Fish & Wildlife Forensics Laboratory, 1490 East Main Street, Ashland, Oregon 97520, USA.*

The Snake Rake: A New Tool for Collecting Reptiles and Amphibians

Conant and Collins (1991) described several useful tools for collecting reptiles and amphibians including traditional snake hooks and potato rakes. The most useful tools in the field are often those that can serve more than one purpose. Unless one is planning on a single activity such as pinning snakes or raking through leaf litter, a multipurpose tool is advantageous. I have designed a simple, multipurpose tool for use in the field.

The snake rake, as I call it, is constructed from a 120 cm length of 19 mm diameter aluminum pipe and two 25 cm long pieces of 6.5 mm diameter steel round stock (Fig. 1). The two pieces of round stock are each bent 90 degrees at a point equidistant from the ends. The two pieces of round stock are then welded together along one length with the unattached ends directed roughly 25 degrees away from each other. The head is then attached to the end of the aluminum pole using two 27 mm hose clamps seated over the welded portion. This creates a two-tined fork that can be used to rake through leaf litter, roll logs and rocks, pin snakes and, lift bark and boards. This design is convenient when traveling since it can be disassembled for transport.

The snake rake can be constructed at home with a few tools. If welding materials are not available contact a local welding shop. Using heads that were constructed by a welding shop, I have assembled several rakes for less than twelve dollars each.

I have used snake rakes in habitats ranging from Ecuadorian cloud forests to Californian deserts and have found it to be a strong walking stick as well as a versatile tool. Low cost of construction and availability of materials add to the appeal of this design.

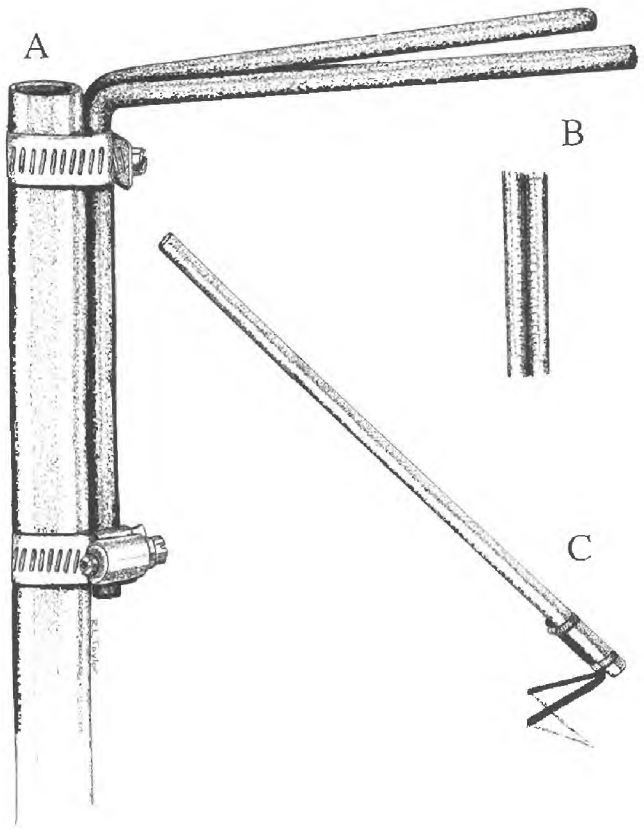

FIG. 1. (A) Detail of head of snake rake. (B) View of weld joining tines in plane of shaft. (C) Snake rake (120 cm).

A Photographic Mark-Recapture Method for Patterned Amphibians

Studies involving mark-recapture in amphibians have employed a variety of techniques that facilitate the identification of individuals (Donnelly et al. 1994; Ferner 1979). The most widely used of these has been toe-clipping (Hillis and Bellis 1971; Twitty 1966; Wells and Wells 1976) and tagging (Elmberg 1989; Massey 1970; Nickerson and May 1973; Woolley 1973). More recent innovations include fluorescent marking (Nishikawa and Service 1988; Taylor and Deegan 1982), radioisotope tagging (Hardy 1985; Semlitsch 1981), and PIT (passive integrated transponder) tagging (Camper and Dixon 1988).

Ferner (1979) suggested the ideal method of recognizing individual salamanders was to use their variation in integument pattern. Hagstrom (1973) photographed ventral patterns of *Triturus cristatus* and *T. vulgaris* to identify individuals, and Healy (1975) used differences in dorsal spot pattern to distinguish between individual *Notophthalmus viridescens*. Loafman (1991) described a technique by which individual spotted salamanders (*Ambystoma maculatum*) could be recognized by their spot pattern.

Herein I describe an inexpensive photographic technique in which individual amphibians can be recognized by their dorsal patterns. Advantages of the technique include: 1) Animals are not physically harmed in any way, 2) animals are permanently "marked," and 3) the technique is easy to use, relatively time-efficient, and inexpensive.

A camera box (15 X 18 cm X 25 cm high) is constructed of 1.6 cm thick plywood, with a hole (7.1 cm diam) in the top to fit a 35-

mm camera lens (Fig. 1). A second hole (1.5 cm diam), also in the top, allows the insertion of a penlight. The bottom of the apparatus is removable and holds a small box in which specimens are placed (Fig. 1). The specimen box is sized appropriately to preclude movement during photography. A strap with a snap holds the bottom in place while the box is being carried or not in use. The stage (bottom) is painted black and is equipped with an adhesive label that can be numbered each time a different animal is photographed. The penlight eliminates the need for using a flash, which would require a more elaborate design. Although amphibians could be photographed without such an apparatus, the box allows consistency in photographic quality, and helps keep salamanders motionless while being photographed.

I have successfully employed the technique in the mark-recapture of 128 adult *Ambystoma opacum* in south-central Louisiana in 1991–92. Nesting females placed on their nests (after being photographed) were found to reattend their eggs in nearly all cases. Eight salamanders (6%) were identified as recaptures using the technique. Sampling bias (due to subterranean nesting) is believed responsible for the low recapture rate.

Salamanders were recognized by their distinct barring, including appearance and number of bars on the dorsum. No apparent ontogenetic change in pattern (an assumption of the technique) was seen over a one-year period; use of the technique with juvenile *A. opacum* would not be informative. As with *A. maculatum* (Loafman 1991), the head patterns alone of *A. opacum* in this study were often (80% of the time) different enough to distinguish between individuals.

A 35-mm camera and color print film (200 ASA) were used. Prints were easier to compare than were slides, and were placed in a photo album where they were labelled accordingly. Photographs of recent captures could then be compared to each previous photograph in the album.

Because individual *A. opacum* often display digit anomalies such as varying numbers of toes or branching of regenerated toes (pers. obs.), and because regeneration of toes can present problems in the identification of marked individuals (Ferner 1979), toe-clipping was not used. *Ambystoma opacum* metamorphs and juveniles show variable regeneration rates depending on the nature of the clip, but the technique is at least somewhat successful, and may be effective on adults (D. Scott, pers. comm.).

Pit-tagging is desirable because marking is permanent, the procedure is simple, and the tags are reliable. However, both the initial cost (tag reader) and individual tags are relatively expensive (Table 1).

TABLE 1. Comparative costs (in US $) of photography and the two most widely used techniques for marking salamanders (* = based on 50% recapture rate, ** = example for N = 300 salamanders marked).

Technique	Initial cost	Cost/salamander	Total**
toe-clipping	$ 5	no cost	$ 5
photography	$ 12	$ 1.06*	$ 330
PIT-tagging	$ 950	$ 5.75	$1725

Donnelly et al. (1994) recommended consideration of time and resources (as well as characteristics of the target organism) as important in the choice of marking technique for amphibians. Where expense is not a factor, PIT-tagging may be the preferred marking technique, particularly when very large numbers of animals are to be marked. Given a funding constraint, one is left with either toe-clipping or photography as a marking technique. Toe-clipping, while the most inexpensive (Table 1), is impeded by regeneration and may adversely affect the animal. Photography as a marking technique is intermediate in cost compared to other methods (Table 1), and is the least damaging of the available techniques.

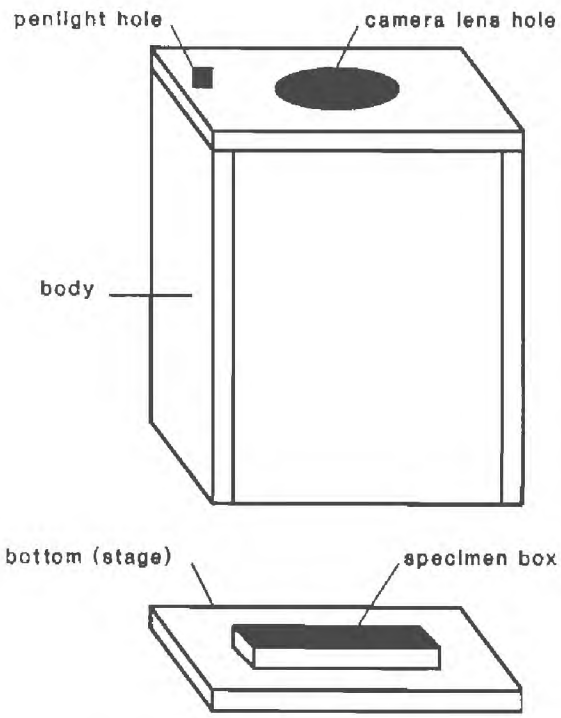

FIG. 1. Basic diagram of camera box for salamanders.

Pitfalls of the photographic technique include the expense of film (ca. $0.29/picture) and film processing (ca. $0.42/print), and the box is slightly cumbersome in the field (approx. wt. = 2090 g). Overall the box has been shown to be reliable for identification of *A. opacum*, was used successfully on several *A. maculatum* and a few *Rana utricularia*, and may be useful for a number of patterned amphibians as a preferred method in mark-recapture studies, particularly those constrained by money.

Acknowledgments.—I thank Jeanne Young, Daniel Doody, Jim Armacost, and Jeff Tamplin for their assistance in the field.

A Method for Catching Lizards in Trees and Rock Crevices

A number of methods have been described for catching diurnal, active, and easily seen lizards, including pit fall traps, nooseguns, and rubber bands (Cogger 1992; Simmons 1987). A baited noose and plastic tube refugia were presented as capture methods by Strong et al. (1993). None of these methods is particularly successful on sedentary animals that inhabit tree hollows or rock crevices. To date the only method for extraction of these animals from their refugia has been through general harassment until the animal moves out. On many occasions this method results in the destruction of habitat, and/or harm to the animal.

During the wet season (November 1992–March 1993), a study commenced on the spotted tree goanna (*Varanus timorensis similis*) (Christian, unpubl. data). This is a pygmy goanna with a maximum snout-vent length of 230 mm and a maximum mass of 200 g. Average size is 186 mm SVL (SD = 26.2, N = 70) and 84 g (SD = 36.1, N = 69). The study site was located 30 km east of Darwin, Northern Territory, Australia. The goannas were found to frequent the hollowed center of wooden posts in an abandoned fence line. The depth of the central hole ranged from 200 mm to 1500 mm.

The two materials used in the extraction of the lizards from the hole were a set of stainless steel forceps (500 mm) to grasp the animal, and a length of wire (1500 mm long) with a hook at one end. The wire was a piece of plain fencing wire 2, 3, or 4 mm diameter (16, 10, or 8 gauge) bent to form a U-shape at one end. The sharp end of the U was bent back upon itself so that it did not have any rough or sharp edges (Fig. 1). A handle was made by bending 80 mm of wire at the top at 90°. The handle was bent in the same direction as the hook section so that when the hook was down a hole, it was possible to determine the direction it was facing.

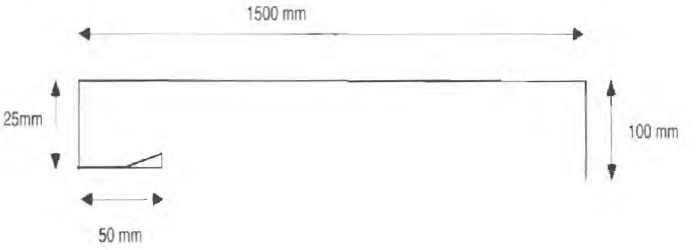

FIG. 1. Diagram of wire hook used to extract *Varanus timorensis similis*.

An animal was first sighted in a hole using a small flashlight, with note taken of its depth and orientation. The hook was then passed down the hole over the back of the animal until it was in line with the anterior third of the animal's tail, but below the legs, assuming the animal was facing the entrance of its hole. The hook was then turned so the tail was encompassed by the hook. At this point the legs acted as a towing point so when the hook was lifted it was positioned around the base of the tail and held by the back legs. The lizard was then lifted in a smooth motion to the top of the hole. The constant pressure on the hook when lifting the animal prevented it from turning around. When the animal was in reach it could either be grasped by the head with the forceps or pulled completely from the hole with the hook. Sometimes an animal turned around in the hole or was facing the wrong direction. A little more care was then needed to extract the animal; in most instances the animal was lifted at mid-body to a point where it could be grasped with the forceps and manipulated to allow the hook to pull it completely from the hole. Lizards could be extracted from shallow holes using only the forceps.

The combination of forceps and hook is the most effective method used by us to date for the capture of *V. timorensis similis*. During a twelve-month period, over 200 animals were caught using this method. The average time taken to catch an animal using this method was 3 min. Circumstances determined which type of wire was used. We were successful using both stiff and soft wire. Some words of caution should be expressed. Although this method is less damaging to the habitat and offers substantial benefits in reduced capture time of animals, it is possible to injure the animal. The most important point is to always make sure the hook is blunt with NO sharp or protruding edges. The hook should be around the base of the tail of the animal before pulling upward. It is an easy mistake to think the hook is around the tail when it has actually penetrated the cloaca. Therefore it is necessary to watch the progress of the hook using the flashlight during the initial positioning around the tail. The same caution holds for animals facing away from the opening. It is possible for an animal to open its mouth in an aggressive stand when facing this way, and the hook to enter its mouth. When first developing the hook system, we encountered penetration of the cloaca three times; however, all animals survived and were released at the point of capture.

We believe this technique should be applicable to both tree and rock-inhabiting lizards.

Evaluation of a New Miniature Temperature Data Logger

Peterson and Dorcas (1994) described the advantages of using data loggers to measure variation in the environment. Scientists may be reluctant to use data loggers in field studies until their usefulness and reliability have been demonstrated. We used a new, miniature temperature data logger to measure the temperatures of nests and hibernacula of wild desert tortoises (*Gopherus agassizii*) at Yucca Mountain, Nye County, Nevada. Here we report on the accuracy, reliability, and ease of use of these data loggers. Reference to a company or product name does not imply approval or recommendation of the product by the U.S. Department of Energy to the exclusion of others that may be suitable. Quoted costs are from a published price list and are reported in U.S. dollars.

We obtained 30 reusable, temperature data loggers (Hobo-Temp, Onset Computer Corporation, Pocasset, Massachusetts; cost $99 ea.), contained in cylindrical plastic cases (35-mm film canisters) that were 3.3 cm in diameter and 5.3 cm long. Each unit with its case weighed 28 g. Measurable temperature range was -39 to 123°C, although other standard and custom ranges were available. Specified accuracy was 0.6°C from 0–40°C, 0.8°C at -10°C, and 1.0°C at -20°C. We chose units with internal thermistors, though units with an external thermistor were available for an additional $18 per unit. Each data logger could store 1800 measurements in nonvolatile memory. The data loggers could be programmed to measure temperatures over 31 possible durations from 15 min to 360 days with corresponding time intervals of 0.5 s to 4.8 h; they could not be programmed to measure temperatures at rounded intervals such as every hour. We used DOS and Windows versions of the program BOXCAR and a package of DOS programs called HOBO-PC (cost $49 ea.) to set sampling duration and other options and to download data. Data loggers were connected to a computer using a 9-pin to 3.5-mm stereo-jack cable (cost $9). We sealed the cases with cloth tape and/or silicone sealant to prevent the lids from leaking or coming off.

We tested the accuracy of the data loggers at 10°C intervals from -20 to 40°C using an oven (Delta Design, model 3900) and a calibrated thermometer (Instrulab, model 4202, system accuracy ≤0.04°C within tested range). Accuracy averaged 0.34°C (SD = 0.23°C) with a maximum error of 1.03°C. The data loggers were within manufacturer's specifications on 94% of the measurements, and the maximum deviation from the specifications was 0.2°C.

We used the data loggers in the field to measure temperatures of desert tortoise nests and hibernacula. In January 1993, we glued data loggers to the carapaces of three radio-marked, hibernating tortoises that were near their hibernacula entrances. We set the data loggers to record temperatures for 90 days at intervals of 1.2 h. We placed glue (Devcon Plastic Welder) on the data logger case and then pressed the case against the carapace without moving the tortoise. We pried the data loggers from the carapace of each animal after it left its hibernaculum in March 1993.

We placed 23 data loggers in desert tortoise nests at depths of 3–24 cm during May-July 1993 to measure nest temperatures. We programmed these units to record temperatures for 122 days at intervals of 1.6 h.

We judged the reliability of the data loggers based on whether all data were acquired by each data logger. No data loggers placed on tortoises or in nests failed. All data were within expected ranges.

We judged ease of use of the software subjectively. All programs were simple to use and worked well. We found that the delayed start-up option, whereby data sampling could be initiated without a computer by removing and re-inserting the battery, was not ideal because the time recorded by the data logger automatically started at midnight of 1 January 1980 and had to be corrected after the data were downloaded. If the start time and date were not recorded manually, this information was lost. For this reason, we preferred using a laptop or handheld computer to start data loggers in the field. We had to ensure the computer's internal clock was accurate because that is where the data loggers obtained the start time and date.

We preferred using the Windows version of BOXCAR when first learning how to start-up and download data loggers because all of the options were visible on a menu. However, when starting-up or downloading many data loggers or when translating many files to a spreadsheet format, the programs included with HOBO-PC were beneficial because options could be set using a batch file. This reduced the chance of selecting an incorrect option.

We found the Hobo-Temp to be a reliable and easy-to-use temperature data logger. A more advanced product now available features rounded sampling intervals (e.g., an interval of one minute or one hour), a switch for starting units in the field without a computer and without loss of time data, programmable start times, averaging of multiple samples, and storage of up to 32,000 measurements. In addition, similar products are available for measuring relative humidity, light intensity, voltage, pressure, and vibration. A waterproof case that is made for the temperature and light intensity data logger may enable use in wetter climates and aquatic habitats, but the relatively large size of the waterproof case (6 cm in diameter and 10 cm long) reduces the advantage of the data logger's small size. Though, data loggers will undoubtedly evolve into smaller and more feature-rich units, biologists already have access to useful miniature data loggers that are valuable tools for field studies.

Acknowledgments.—This work was funded by the U.S. Department of Energy, Yucca Mountain Site Characterization Project, under contract No. DE-AC08-93NV11265. Permission to handle desert tortoises was granted by the U.S. Fish and Wildlife Service through permits PRT-683011 and

PRT-781234 and by the Nevada Division of Wildlife under permits S 6941 and S 9060. We thank Kurt Rautenstrauch, Tom O'Farrell, Kent Ostler, Chuck Peterson, Michael Dorcas, and David Germano for reviewing this manuscript.

HERPETOLOGICAL HUSBANDRY

Notes on the Captive Husbandry and Reproduction of the Texas Salamander *Eurycea neotenes* at the Dallas Aquarium

The Texas salamander, *Eurycea neotenes*, is one of several hemidactyliine neotenic plethodontid salamanders endemic to the waters of the Edwards Aquifer of south central Texas (Chippindale et al. 1992). They are distributed throughout the aquifer (Dixon 1987), and their taxonomy is currently being evaluated (Chippindale et al. 1992).

The Edwards Aquifer is a subterranean reservoir with outflow water surfacing at many points. The waters of the aquifer have been taxed heavily in recent years by cities, farms, and industries. Five species found in the aquifer are listed as endangered; consequently there is much concern for the welfare of the endemic wildlife of the area. Proper management of this aquifer is vital to the survival of these species.

In the spring of 1990, during a prolonged drought and continued heavy human use of water, parts of the Comal Springs began to dry rapidly. The Edwards Aquifer Research and Data Center (EARDC) at Southwest Texas State University organized the field collection of 80 *E. neotenes* during June 1990. A conference was called to receive input and opinions regarding the depletion of the aquifer's water and the resulting threats to the environment. United States Fish and Wildlife Service, EARDC, San Marcos National Fish Hatchery, Texas Parks and Wildlife, and four North American zoos/aquariums were represented at the conference. Salamanders collected prior to the conference were distributed among interested institutions with the hope that detailed data could be collected regarding the husbandry and reproductive strategies of this little known species. Naturally deposited eggs of neotenic *Eurycea* found in the Edwards Aquifer have never been discovered in the wild, despite concerted efforts.

The Dallas Aquarium acquired 20 specimens from the EARDC, a portion of which were divided into presumed pairs. Three pairs were housed individually in separate 3.8 L aquaria with a constant flow of fresh water from the aquarium well. Temperature of the well is a constant 22°C with pH ranging from 7.5–8.0 (Table 1). Overflow ports were fitted to the back of the aquaria to allow for water drainage. Wild specimens of *E. neotenes* have been collected in gravel substrate, dense submerged aquatic vegetation, and under rocks (Bruce 1976; Sweet 1977), so tank furniture was varied for each enclosure. Additionally some *Eurycea* spp. are known to deposit their eggs on the underside of buried rocks (Ireland 1974). The first aquarium was furnished with a 7 cm gravel substrate, the second was heavily planted with *Vesicularia dubyana* and *Hygrophila* sp., and the third was half filled with partially buried rocks and rock shards. The remaining individuals were housed in a 189.3 L aquarium with constant water flow and no furnishings other than several 25 cm sections of 1.3 cm (1/2 in) PVC pipe. All aquaria were positioned under a skylight to provide natural photoperiods. No other lighting was provided. Live foods offered included tubificid worms, *Gammarus* sp., and adult *Artemia* sp. Salamanders were observed feeding at various times of the day on all food types.

TABLE 1. Dallas Aquarium water composition.

Parameters:	
pH	7.5
Turbibity (NTU)	0.04
Chlorine	0.0
Total suspended solids	0.0
Total dissolved solids	635.

Total phosphate as P	0.11
Demand:	
Total BOD_5	0.9

All results are in mg/L except pH, or as indicated.

Little activity was observed during daylight hours. Nocturnal activity was recorded on videotape with tinted red lighting as a source of illumination. Salamanders were observed feeding and moving throughout the enclosures with very little interaction noted between individuals. On 22 August 1990 an adult female in the planted tank exhibited obvious egg development, visible through the translucent abdominal wall. The following day a presumed male was observed chasing this female, but no other breeding or courtship behavior was observed. In the following months all animals were closely observed for egg development and/or courtship behavior. Nothing significant was recorded during this period.

During the evening hours of 18 and 19 February 1991, the gravid female deposited 19 white eggs, 2 mm diam, each surrounded by

a gelatinous envelope, and fixed singly to live plants. The eggs were moved to a separate tank to ensure there would be no predation by the adult salamanders or snails present within the breeding enclosure. After a period of 48 h, the incubation tank was covered with black polyurethane to exclude light, addressing the concern that light intensity might have any deleterious effect on the egg development. Embryonic development was documented by photomicrographs. Several eggs developed a fungal growth and were preserved. Between 5–10 March 1991, four eggs hatched. One larva was deformed and expired immediately. Upon hatching, the larval ground color was a creamy white with scattered pale tan dorsal speckling. The larvae possessed rudimentary external gills, no limbs, and an unpigmented iris. TL of hatchlings was 7 mm. Front limb development began with buds visible two days post hatching. Within four days, front legs were complete with digits, and larvae exhibited brown dorsal pigmentation with paired light colored vertebral spots. Hind limb development was observed on 15 March with digits visible on all four legs by 24 March. At 30 days post hatching, larvae were 15 mm TL and began feeding on live newly hatched brine shrimp nauplii, confirmed by the bright orange color of the brine shrimp visible through their translucent abdominal skin. At age two months, the young salamanders were 26 mm TL, and by 6 months of age the largest offspring measured 60 mm TL and showed signs of ova development. At one year post-hatching, two of the three offspring were obviously gravid with fully developed eggs. The third individual showed no ovarian development and was presumed to be a male. No other reproductive behavior was seen in the adults for a period longer than 1.5 yrs. The cues that triggered the first reproduction are unknown.

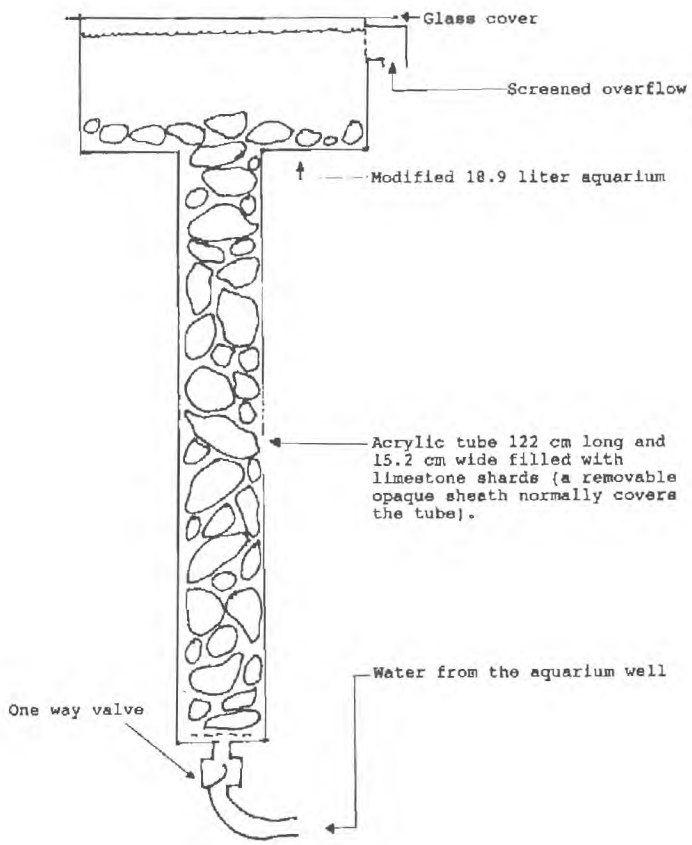

FIG. 1. Schematic of artificial aquifer.

The EARDC found that *E. nana* larvae of different ages can be collected in nets positioned over spring upwellings (Glenn Longley, pers. comm.). Our extended underwater observations in Comal Springs led us to hypothesize that the salamanders travel downward into the spring upwellings to deposit their eggs.

To test this hypothesis, we constructed an artificial aquifer consisting of a 122 cm long, 15.2 cm diam acrylic tube filled with limestone shards and fitted to the bottom of a 18.9 L aquarium (Fig. 1). Water was pumped upwards through the tube and exited through a screened overflow at the top of the aquarium. Flow rate for the artificial aquifer was measured at 5.5 L/min. The tube was equipped with a removable opaque covering to simulate the darkness of an underground aquifer and to permit periodic observations.

One of the original pairs and one F_1 pair were placed in the artificial aquifer on 23 February 1993. The original male was 91 mm TL and the female was 74 mm; the F_1 male was 76 mm TL and the F_1 female was 65 mm TL. Eggs laid by the F_1 female were discovered 38 days (2 April 1993) after the animals had been placed in the aquifer. Based upon rate of development of the previous clutch, the eggs appeared to be 2–4 days old. They were attached singly to rock shards in the lower portion of the aquifer. Hatching occurred ca. 12–13 April. On 10 May 1993 the founder female deposited more than 40 eggs in the artificial aquifer. The larval development subsequent to this oviposition differed from the two previous reproductions. A few of the larvae hatched, unpigmented and with no limb development on 30 May, but the majority of the larvae hatched between 6 and 13 June. The latter group of larvae hatched in a more advanced state with pigmentation of skin and iris diaphragm, and development of front limb buds. After hatching, 20 of the larvae were removed and placed in a separate aquarium for rearing. The remainder of the larvae were left in the parent enclosure for approximately two months. No predation on larvae by the adults was observed during this time. Neonates were then removed from the aquifer and divided between two rearing tanks.

On 13 March 1994 the founder female deposited at least 50 eggs in a similar fashion to her first reproduction on May 1993 in the artificial aquifer. Five eggs were removed to facilitate close observations of larval development.

We believe these three ovipositions in the artificial aquifer represent the "normal" reproductive mode of this species and may explain the difficulty of observing their eggs in nature. This propagation technique is now being tested by the U.S. Fish and Wildlife Service in an attempt to reproduce the closely related, but endangered San Marcos salamander, *Eurycea nana*.

Acknowledgments.—Support for this study was generously funded by the Dallas Zoological Society. We thank Dr. Glenn Longley of EARDC for hydrologic and hydrochemical data of the Edwards Aquifer and for photographs of the habitat. We also thank Dr. Tom Brandt and Casey Berkhouse of the National Fish Hatchery at San Marcos for their expertise, David Whatley of the New Braunfels Parks and Recreation Department, the Texas Parks and Wildlife Department, and the United States Fish and Wildlife Service for all necessary permits. Finally we thank the staff of the Dallas Aquarium, the Dallas Zoo Department of Herpetology, and L. Ardell Mitchell, for helpful suggestions on this manuscript. Without such cooperation, this study would not have been possible.

Collecting and Feeding Harvester Ants (*Pogonomyrmex* spp.) to Captive Horned Lizards (*Phrynosoma* spp.)

Although ants, especially harvester ants of the genus *Pogonomyrmex*, are consumed in large numbers by many species of *Phrynosoma*, or horned lizards (Montanucci 1989a; Munger 1984a, b; Pianka and Parker 1975; Rissing 1981; Sherbrooke 1981, 1987; Whitford and Bryant 1979), ants are not a nutritional prerequisite for these lizards (Sherbrooke 1987). Other insects are part of the natural diet of horned lizards and may be accepted by captive animals. Nevertheless, including ants as a major component of the diet can facilitate the feeding and maintain the health of horned lizards in captivity (Baur 1973; Montanucci 1989b, c, d; personal observ.). Difficulties are frequently encountered both in procuring sufficient numbers of ants and in presenting the ants to the lizards in a fashion that ensures that they can be captured and eaten. Such difficulties have thwarted *Phrynosoma* research, and efforts to exhibit and maintain captive lizards.

In this report I describe hazards and precautions one should take when collecting harvester ants, as well as three successful methods of collecting *Pogonomyrmex* in large numbers. Also, I explain methods for feeding harvester ants to horned lizards in indoor and outdoor enclosures. The *Pogonomyrmex* species most commonly collected near Tucson and Portal, Arizona, were *P. rugosus*, *P. occidentalis*, and *P. desertorum*.

Caution must be exercised in handling *Pogonomyrmex* ants as they are capable of inflicting severe stings (Schmidt 1986), to which some people may have an allergic reaction. People with known allergic reactions to hymenopterans should not try to collect *Pogonomyrmex* ants. Harvester ants defend attacks on their colonies by orienting toward and climbing tall objects. If this is the collector, they will sting. Frequent stamping of the feet effectively dislodges ants from shoes (sandals/thongs should not be worn). By exposing skin on the legs, wearing shorts or rolling up long pant legs, one can feel or see climbing ants on the bare skin and quickly brush them off before they bite or sting. I was occasionally stung on the finger while picking up ants, usually when an ant managed to get between digits. Rubber gloves reduce this risk.

The first technique is used to collect surface-foraging workers that are returning to the entrance of a large colony. Large numbers of individual seed-harvesting ants are active on the surface in the morning and afternoon, depending on climatic conditions. A small depression in the soil (2–5 cm diam) is created at the colony nest entryway, the downward extended tunnels of which are plugged with soil to prevent subterranean escape of trapped ants. Returning ants fall into the depression, where they are trapped in the inverted cone in a fashion similar to that seen in an antlion trap. Continuously arriving ants accumulate in a writhing mass, digging, trying to climb the walls, and attacking each other. Every few minutes I collect ants by swiftly picking up the mass of ants with the tips of my first three fingers and thumb of one hand and quickly drop the ants into a glass jar with a screened lid, from which they can not escape. The procedure is repeated when a sufficient number of arriving forager ants have again gathered at the plugged tunnel entrance. During periods of peak harvester ant activity, hundreds to thousands of ants can be captured in a short time. A person may work several colonies simultaneously by allowing ants to accumulate at one colony entrance while collecting ants at the entrance of a nearby nest. Ants collected in this fashion should be fed to lizards the same day or they will die, probably because of desiccation. Dead ants are not accepted as food by horned lizards.

The second collecting technique is used to capture subsurface workers, and can be employed whether colonies are active or inactive on the surface. Since it involves excavation with a pointed shovel, the selection of site (amount of rocks and compaction of soil) will influence the difficulties encountered in capturing large numbers of ants. A hole is dug 10–30 cm deep in the colony entryway forming a cone-shaped pit, again roughly similar in form to an antlion trap. As defending ants exit from tunnels they are trapped in the pit. They collect in the bottom, trying to climb the walls. The ants can then be scooped up with a shovel, along with loose soil, and dumped into a portable container. Clean 5-gallon (18.9 L) plastic buckets work well, as the ants have difficulty climbing the smooth sides. The goal to keep in mind is to maximize the number of ants and minimize the amount of soil/rocks per shovelful/bucketful. The buckets should not be more that three-quarters filled with soil and ants. It is frequently possible to work several colonies in one area simultaneously, leaving each colony to gather more ants between shoveling bouts. Keep ants from each colony in separate buckets to avoid intercolony strife.

When moisture levels are high at the soil surface numerous subterranean workers may be encountered very near the surface. Frequently brood chambers are unearthed. Seasonally these yield large numbers of workers, alates, some callows, and brood (which are not usually eaten by the horned lizards). Sometimes ant activity in these near-surface chambers can be stimulated by flooding the soil with water, where feasible, several days in advance of digging. Advantage can be taken of the climbing behavior of colony-defending ants by scooping up ants congregating at the tops of piles of soil. Again, the collector needs to constantly be on the alert to avoid ant stings.

For transport in an automobile, buckets can be covered to prevent ant escape. If being transported in the back of a pickup truck this is not necessary, but the soil in each bucket should be shaded

to prevent long exposure to direct sunlight and desiccation of ants on the surface.

The third technique takes advantage of seasonal windfalls of alate ants congregating at lek sites. This requires knowing the timing, climatic stimuli, and lek siting of particular species of *Pogonomyrmex* (Hölldobler 1976). Flying, alate harvester ants of high caloric value can be netted with an insect net. When large numbers of reproductives are collected they can be refrigerated to extend the period of use as live food.

Lizards maintained indoors should be in enclosures at least one meter square, and equipped with proper heating and ultraviolet lighting (Sherbrooke 1987). A sand substrate facilitates burrowing by the lizards. Because excited ants prefer to climb, an elevated "hill" away from the sides and towards one end of the cage serves to keep ants more or less concentrated at one location in the cage during feeding. The concentration of ants, and the maintenance of ant-free areas are critical to stimulating feeding by the lizards. Initially, lizard feeding behavior may be inhibited by the presence of an observer, but after several days the lizards associate the observer with ants, alleviating the problem.

The rate of introduction of ants into the enclosure is critical, and is dependent on the rate of consumption of ants by the lizards. Initially only small numbers of ants (5–10) should be introduced, then following ingestion by the lizards, they can be replaced and augmented. The number of ants in a cage should never be so great that their activity results in ants becoming dispersed throughout the cage. When ants surround lizards on all sides the lizards may stop feeding, and may attempt to escape the enclosure. Non-feeding lizards may become objects of ant attack, and, although they have resistance to ant stings (Schmidt et al. 1989), mandibular bites appear to cause the lizards some discomfort.

Feeding can be facilitated, especially of ants dug up with soil, by maintaining lizards in outdoor enclosures. This eliminates the need for artificial lighting and heating in areas and seasons where the climate is appropriate. Enclosure walls must be buried deeply enough and be high and smooth enough to prevent lizard escape. In addition, enclosures must be protected from predators (wire mesh enclosure covers work well), and large enough to allow entry for feeding and other care of the lizards. In recent years I have used a 4.5 m x 5.5 m x 2.2 m high cage, divided into four 2.65 m x 2.13 m compartments, each surrounded by 0.6 m high sheet metal (28 gauge) walls. A 0.3 m cement footing-wall prevents subterranean escape of lizards and entry of predators.

These large enclosures are ideal for feeding ants mixed with soil in 5-gallon (18.9 L) buckets. The contents of the bucket, or several buckets (depending on numbers of ants and lizards) can be dumped on the center of the cage floor, building an elevated hill over time (which eventually must be removed). Lizards learn to approach this rise and feed on descending ants, while still having the entire periphery of the cage as a retreat. Ants frequently begin building burrows into the loose soil of the mound and, once established below the surface level, live for several days or longer without dying of desiccation. Ants in buckets can be maintained for a few days if the soil is kept damp and the buckets are not in direct sunlight.

Utilizing harvester ants with other foods (other ants, crickets and mealworms), I have maintained in captivity all seven species of horned lizards that occur in the United States for periods of weeks, months, and even several years. The best dietary mix varies with species of *Phrynosoma* (Montanucci 1989a; Pianka and Parker 1975). The numbers of lizards held was usually between fifty and one hundred, mainly for season-long behavioral studies, particularly with *P. cornutum*, after which they have been released at sites of capture. Thus, I have maintained large numbers of horned lizards in excellent condition for long periods of time and with most animals gaining significant weight. Occasionally individual animals do not adapt well to captivity in spite of these methods.

Acknowledgments.—G. A. Middendorf, III, and E. E. W. Sherbrooke provided valuable editorial assistance, as did the editor and reviewers. Scientific collecting permits were supplied by the Arizona Game and Fish Department, New Mexico Department of Game and Fish, and the California Department of Fish and Game.

Captive Breeding of Two Species of *Eleutherodactylus* (Anura: Leptodactylidae) from Puerto Rico, with Notes on Behavior in Captivity

Frogs of the genus *Eleutherodactylus* comprise an extremely successful and speciose group in the tropical Americas and the Caribbean. While the biology of several of the 500-plus known species has been investigated, little or nothing is known of the majority of these frogs, and new species are regularly being reported (e.g., Flores 1993; Hedges and Thomas 1992; Wiens and Coloma 1992). As a tool for the study of *Eleutherodactylus*, methods are described here which have been used to successfully breed in captivity two common species from Puerto Rico, *E. coqui* and *E. cochranae*.

Eleutherodactylus coqui is an ecological generalist occurring nearly island-wide in Puerto Rico, on adjacent islands, and in small introduced populations in Florida and Louisiana (Conant and Collins 1991; Rivero 1978; Schwartz and Henderson 1991). *Eleutherodactylus cochranae* is a much smaller and relatively unstudied frog, apparently restricted to the lowlands of Puerto Rico and several of the Virgin Islands (Rivero 1978; Schwartz and Henderson 1991). Both species were collected from backyards and gardens in the coastal town of Dorado, Puerto Rico during 1991–1993. Typical habitats in the collecting area consisted of moist bromeliads and ferns in cultivated gardens.

In captivity, frogs were housed in 10-gallon glass aquaria—51 cm (length) x 26 cm (width) x 32 cm (height)—with special provisions for the presence of suitable retreat sites, moisture, heat, and light. The substrate of the cages consisted of a single, level layer of approximately 1 cm diam natural stream pebbles, partially covered by ca. 1 cm of moist, untreated peat moss, both of which were obtained from local pet or garden supply stores. Smaller diameter pebbles were avoided as they posed a danger of ingestion during feeding. Retreat sites were provided by placing one or more small, locally purchased, potted bromeliads in each tank (*Guzmania* or *Vriesea* species). Care was taken to wash the bromeliads thoroughly to remove any pesticide or fertilizer residue prior to their placement in the aquaria. Cages were kept at a high level of humidity by both mist spraying and direct watering of the bromeliads with bottled spring water. Spraying and watering were performed as necessary to provide small puddles of water in the bases of the bromeliad leaves and to maintain a moist, but not wet, substrate. Humidity was retained by covering the screen cage top with a sheet of plastic wrap. Minimum cage temperatures were kept above 22°C by inserting a submersible 50 or 75 watt aquarium heater into a narrow-mouthed, 1 L plastic bottle filled with water and taped shut to prevent evaporation. These heating devices provided a "soft" heat source which did not present a burn or desiccation hazard. They were placed in the corner of tanks to provide a thermal gradient across the enclosure. Fluorescent lights (15 watt, General Electric) placed directly on the top of each cage raised the maximum temperature during the day to 25–27°C. The lights were placed on a timer to provide a 12 h diel cycle.

An attempt was made to provide as diverse a diet as possible to the frogs. During warm weather, adult frogs were fed a variety of moths attracted to outdoor lights, various hand caught spiders, grasshoppers, termites, and other easily captured insects. During the winters, the diet consisted almost entirely of locally purchased crickets (*Acheta domesticus*), house flies (*Musca domestica*), and locally cultured fruit flies (*Drosophila melanogaster*). While activity continued year round for both species, frogs showed decreasing interest in any one food type after prolonged feeding in the absence of other varieties. Feeding frequency was adjusted to accomodate the relative hunger level of each frog. For general maintenance this usually consisted of a sufficient quantity of items to equal approximately one fifth the frog's weight, twice a week.

In captivity, both species of frogs appeared to call normally and engage in apparently typical behaviors. Male advertisement calling, satellite behavior, and territory and retreat defense, as well as mating and parental care were all observed. Male *E. coqui* and *E. cochranae* both gave advertisement calls similar to those previously described (Drewery and Rand 1983). However, the calls of *E. coqui* collected at Dorado were of higher frequency than those previously reported from frogs at El Yunque (Drewery and Rand 1983; Narins and Capranica 1976; Stewart and Rand 1992). This is in agreement with the observed altitudinal variation in call frequency reported by Narins and Smith (1986). During aggressive interactions and territorial and retreat defense in captivity, *E. coqui* males gave multi-note extensions of their mating call, similar to those reported by Stewart and Rand (1991, 1992) and Stewart and Bishop (1994). Female *E. coqui* in captivity also gave occasional aggressive calls as previously described (Stewart and Rand 1991). Aggressive physical interactions observed between *E. coqui* consisted of butting and biting behaviors also previously described (Stewart and Rand 1991; Townsend et al. 1984). In contrast, male *E. cochranae* in captivity used a very different behavior during physical encounters. This consisted of "shoveling" under the opponent and attempting to dislodge the opponent from the substrate. This may be an adaptation making use of the flattened morphology of *E. cochranae*. Also unlike *E. coqui*, both sexes of *E. cochranae* gave a retreat defense call differing in pitch and timing from the typical male *E. cochranae* advertisement call.

Both species showed extreme satellite male behavior in captivity. Extra males placed within a tank with a mating pair caused disturbances in the normal mating activities. The extra males engaged in aggressive calling and physical interactions with the resident male. These behaviors usually prevented courtship and nesting. However, on several occasions more than one male was found in a nesting retreat attempting to amplex the female. Females occasionally deposited eggs in these circumstances (as evidenced by thinness and the lack of egg masses seen through the skin the following day), but the eggs were always eaten in those circumstances, apparently by the competing males. Conspecific cannibalism has been reported in *E. coqui* (Townsend et al. 1984), but mating interference as a satellite male strategy has not. However, mating interference has been observed in dense populations of *E. johnstoni* in Barbados (Ovaska and Hunte 1992). It is likely that these behaviors in captivity are a consequence of the confined conditions.

During courtship and mating, males of both species produced soft, repetitive calls similar to those mentioned previously for *E. coqui* (Townsend and Stewart 1986). These calls apparently served to attract the female to the nesting site and initiate amplexus. In captivity, amplexus was maintained by pairs of both species until the following day and undisturbed males remained with the eggs in the nest site during development and for as long as 5 days after hatching of the young frogs, as reported by Townsend et al. (1984) and Townsend and Stewart (1986). In captivity, male frogs protected their egg clutches in a manner similar to previous reports (Taigen et al. 1984; Townsend et al. 1984). During dry periods the fathers moved to other leaf axils containing water, then back to

the nest to rehydrate the eggs. Fathers defended their nests vigorously against intrusion from other frogs, insects, or inanimate objects. Eggs in the care of a male frog seldom developed bacterial or fungal infections: however, removing the eggs to another location nearly always produced infections.

During two years of captivity over 30 *E. coqui* clutches and over 20 *E. cochranae* clutches were observed. Breeding activity took place year-round. *E. coqui* laid 12–30 eggs per clutch (mean = 23), which took 15–33 days to hatch (mean = 22). The much smaller *E. cochranae* laid 5–10 eggs per clutch (mean = 8) which took 16–20 days to hatch (mean = 18). The eggs of both species were of approximately the same size (4–6 mm at hatching, mean = 5, N = 10 for each species). For females of both species, the time between each mating and oviposition was dependent on food supply. In one instance, it took only six days for a female *E. coqui* to lay a new clutch. Seven and eight-day intervals between clutches were not uncommon for either species when food was supplied in sufficient quantity. Since female *E. coqui* have been reported to deposit all of their mature eggs at each oviposition (Townsend and Stewart 1986), these times are indicative of the minimum maturation time for a clutch of ova, and thus the minimum breeding interval. If retreat sites, not food supply, limit natural populations (Stewart and Pough 1983), female eleutherodactylids may be able to produce clutches nearly three times faster than males can incubate them. This minimum breeding interval is considerably faster than the 58-day average interclutch interval reported from three female frogs at El Yunque (Townsend and Stewart 1994).

Similar to reports for *E. coqui* in the field (Townsend et al. 1984), males of both species in captivity rarely moved from their eggs during incubation, and appeared uninterested in insects as food items during brooding. However, fathers regularly consumed a small number of eggs during the course of the incubation. It is not clear whether this is a biologically significant behavior or an artifact of captivity, as males often ate their entire clutches if they or their nests were disturbed. Females of both species were voracious feeders, and appeared capable of consuming nearly their own weight in food items in a single evening, especially after egg deposition.

Hatchling frogs of both species measured 4–6 mm SVL (mean = 5, N = 10 for *E. coqui* and 5 for *E. cochranae*). They remained in the nest, guarded by the father for several days after hatching, at which point they began to disperse. The fathers of hatchling frogs remained uninterested in most insect food items, and did not attempt to eat the young frogs. On the other hand, the mothers were a significant source of predation if left in the same aquarium with hatchlings.

A major problem arose in feeding the juvenile frogs, as they were generally too small to eat even fruit flies (Woolbright and Stewart 1987). Oddly, juveniles of the smaller species, *E. cochranae*, were often capable of taking larger food items than juveniles of *E. coqui* of the same age and size. Without a consistent supply of tiny food items, mortality at the hatchling stage was high, generally greater than 95%. Froglets that were capable of eating fruit flies were raised in moss-filled 150 mm x 20 mm petri dishes placed under the plastic wrap on top of the adult frog aquaria until they were approximately 10 mm SVL. They were then transferred to an aquarium and fed pin-head crickets and small house flies. Information on adult *E. cochranae* raised under these conditions is lacking as juveniles of this species began to develop unidentified neurological problems at 10–15 mm SVL. Symptoms included inability to capture food items, unsteady movements, muscle spasms, and a soft enlargement of the head between the eyes. No captive born *E. cochranae* has survived long enough to reproduce. The reasons for this defect in development are unclear. However, juvenile *E. coqui* developed without difficulty and males reached sexual maturity in approximately 5–6 months, as evidenced by calling. Female *E. coqui* grew to a larger size than males, developed egg masses, and bred at approximately 12 months. Second generation captive *E. coqui* have also bred and produced normal offspring. The oldest frog in captivity was a male *E. coqui* that was collected as an adult in September 1991, and died in July 1994. This individual called somewhat atypically in 1993 and 1994, but was otherwise active and healthy, with no obvious cause of death.

Artificial environments of this type should prove useful for the propagation and study of other species of *Eleutherodactylus*. While the biological significance of observations made in artificial settings must be confirmed in the natural habitat, interesting behaviors noted in captivity can provide excellent direction towards the design and interpretation of field experiments. Captive breeding of these species has allowed intimate observations to be made during evidently normal behavior. These observations have indicated likely differences in biology between these two species, including differences in development, clutch size, call patterns, and aggressive interactions. In addition, captive breeding may be useful for conservation of drastically endangered species, since many species of *Eleutherodactylus* inhabit extremely restricted ranges that have been negatively affected by human activities.

Health and Welfare of Captive Reptiles

Edited by **Clifford Warwick,** *Institute of Herpetology, Worcester, UK.*
Frederic L. Frye, *Fund for Clinical Research, Davis, California,*
and **James B. Murphy,** *Dallas Zoo, Texas*

This clearly written, comprehensive volume fully examines the welfare of captive reptiles and explores the implications of captivity, general husbandry and research programs. The editors, acknowledged experts in this field, have drawn together an impressive international group of contributors in discussions of reptilian physiology, physical and psychological stress, diet and normal behavior. This unique book also considers veterinary and environmental issues, as well as the value of informed design in research.

Contents Physiology and functional anatomy. Biology of stress: Interactions with reproduction, immunology and intermediary metabolism. Nutritional considerations. Veterinary perspectives and techniques in husbandry and research. Naturalistic versus clinical environments in husbandry and research. Normal behavior. Effects of ontogenetic processes and rearing conditions. Behavioral consequences of husbandry manipulations: Indicators of arousal, quiescence and environmental awareness. Psychological and behavioral principles and problems. Ethologically informed design in husbandry and research. Miscellaneous factors affecting health and welfare. Index.

NATURAL HISTORY NOTES

The **Natural History Notes** section (formerly Life History Notes) is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Use of figures to illustrate any data is encouraged, but should **replace** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send two copies of manuscripts, double-spaced, directly to the appropriate section co-editor (addresses on inside front cover). Manuscripts concerning reptiles should be sent to Lee A. Fitzgerald; those concerning amphibians should be sent to Charles W. Painter.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins (1990. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 3rd ed., Herp. Circ. 19:1–41; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhvacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

AMBYSTOMA TEXANUM (Smallmouth Salamander). **MAXIMUM SIZE**. On 22 March 1993, between 2000 and 2100 h, CST, a gravid female *Ambystoma texanum* was collected during a rain shower on the Lake Kinkaid Spillway Road (SW1/4, Sec. 4, T9S, R3W), Jackson County, Illinois. As measured alive (chlorotone anesthetized), the specimen was: SVL = 106 mm; TL = 191 mm (SIUC H-4432, Herpetology Collection, Southern Illinois University at Carbondale). Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin, Boston, Massachusetts, 450 pp.) report the record size for this species as 178 mm (TL). Smith (1961. The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28(1):1–298) reported a 171 mm (TL) specimen as the largest *A. texanum* from Illinois.

Submitted by **MICHAEL REDMER**, 21 West 103 Par Lane, Itasca, Illinois 60143, USA.

AMBYSTOMA TIGRINUM (Tiger Salamander). **REPRODUCTION**. Nussbaum et al. (1983. Amphibians and Reptiles of the Pacific Northwest. Univ. of Idaho Press, Moscow, p. 57.) reports that little is known about the life history of tiger salamanders in the Pacific Northwest, and gives an account of eggs being found in April in Medical Lake, Spokane Co., Washington. On 26 March 1994 we found approximately 75 eggs attached to stems of spikerush (*Eleocharis* sp.) and fallen branches in a roadside swale on the N side of the Frenchman Hills, Grant Co., Washington; SE 1/4 Sec.16, T17N, R26E (Verified by R.A. Nussbaum, UMMZ 205809). Of almost 20 eggs examined, all embryos were at stage 38 (Duellman and Trueb 1985. Biology of Amphibians. McGraw-Hill Book Company, New York, p. 131), indicating they had been deposited approximately two weeks earlier. All eggs had been attached singly, although it was common to see several eggs beside

one another on the same stem or branch. The eggs were found in water ranging between 5 and 30 cm deep. This record demonstrates that breeding may occur in early to mid-March in the Lower Columbia Basin.

Submitted by **WILLIAM P. LEONARD**, Washington Department of Natural Resources-Natural Heritage Program, P.O. Box 47046, Olympia, Washington 98504–7046, USA, and **DAVID M. DARDA**, Department of Biological Sciences. Central Washington University, Ellensburg, Washington 98926, USA.

PLETHODON GLUTINOSUS (Slimy Salamander). **MORPHOLOGY**. On 29 June 1992, while collecting salamanders as part of a long-term capture recapture study, I collected a juvenile *Plethodon glutinosus* 2.5 km W Hwy 160 near Big Black Mountain Ridge Road in Harlan County, Kentucky. The salamander exhibited extreme scoliosis but otherwise appeared in good health. Based on SVL (41 mm from tip of snout to posterior angle of vent), the age of this individual was estimated to be 2 or 3 yrs (Semlitsch 1980. Herpetologica 36:6–16). This estimate may be conservative since the SVL measurement did not include bends in the vertebral column. The salamander was photographed and released. On 20 July 1993 I recaptured this individual (identity verified by spot pattern record) about 1.5 m from the capture point of the previous year. I photographed the salamander (Fig. 1, top) and recorded its SVL (50 mm). It still appeared in good health. A radiograph confirmed external observations that the vertebral column exhibited extreme lateral arches which were most severe behind the forelimbs (Fig. 1, bottom). Thus, the vertebral column abnormality apparently did not inhibit growth or survival under natural conditions. I thank R. G. Wilson for providing the radiograph and C. McCallister for providing photographs.

FIG. 1. Juvenile *Plethodon glutinosus* exhibiting extreme scoliosis (top); (bottom) radiograph of same individual.

ANURA

BUFO TERRESTRIS (Southern Toad). **OOPHAGY**. On 28 March 1993 I observed a congregation of tadpoles feeding on a dead adult female *Bufo terrestris*. I collected the female and tadpoles (N = 114) to examine the nature of the feeding. I also found a second dead female nearby; however, no tadpoles were feeding on it. I collected this female and an additional 200 tadpoles to determine whether the tadpoles would eventually feed on the second female. After 3 days with the carcass and no other food supply, no feeding was observed.

I haphazardly selected 10 tadpoles captured with the first female and measured SVL and stage. Tadpoles were between 6 and 9 mm SVL, and stages 29 to 31 (Gosner 1960. Herpetologica 16:183–190). The first female toad was missing the right front and rear legs (jagged bones were exposed) and her stomach cavity was open. Tadpoles concentrated feeding activity around the opened venter. Within the body cavity the intestines and stomach were intact, but the female was gravid and many eggs were loose. I inspected 10 tadpoles to determine if they were feeding on the eggs. The presence of eggs in 3 of the tadpoles confirmed that the tadpoles were feeding on the eggs.

Cannibalism or oophagy by tadpoles has been documented in numerous species (Crump 1983. Am. Nat. 121:281–287; Polis and Myer 1985. J. Herpetol. 19:99–107). In some species, cannibalism or oophagy can be an important and regular feature of tadpole life history, while in others it may simply be an opportunistic food source. This observation represents the latter, as this type of oophagy is probably rare for *Bufo terrestris* tadpoles.

Submitted by **KIMBERLY J. BABBITT**, Department of Wildlife and Range Sciences, University of Florida, Gainesville, Florida 32611, USA.

HYLODES PHYLLODES (NCN). **PREDATION**. Picinguaba (23°22'S 48°45'W), southeastern Brazil, embraces an area of Atlantic slope rainforest. The small diurnal leptodactylid frog *Hylodes phyllodes* Heyer and Cocroft (SVL 27.5-35.5 mm) is commonly found on or among rocks and roots along small overgrown streams. The pisaurid spider, *Trechalea keyserlingi* F.O. Pickard-Cambridge, is predominantly nocturnal with diurnal activity being restricted to shadowed areas in cracks and under rocks, and is frequently associated with flowing water.

On 9 December 1991, between 1630 and 1700 h, we observed a subadult *T. keyserlingi* (13.8 mm body length) vertically positioned upside down on the side of a rock next to a stream. This spider caught a young *H. phyllodes* (17. 2 mm SVL) by one of its hind limbs as it passed on the leaf litter about 50 cm below. The frog tried unsuccessfully to get away but was eventually immobilized by the spider's toxin. At that moment both were collected and preserved. The spider was placed in the Instituto Butantan Collection (IBU 5319) and the frog in the Museu de Zoologia da Universidade de São Paulo (MZUSP 69850).

The frequency of predation on *H. phyllodes* by *T. keyserlingi* is unknown but may be common, because both species appear to occupy the same microhabitat. Also, since both species attain larger sizes, predation might include adult frogs. Other pisaurid spiders eat fish and tadpoles (McCormick and Polis 1982. Biol. Rev. 57:29–58) suggesting that this species also could prey on *Hylodes* larvae.

Although spiders are often cited as important predators of small frogs, few published records simultaneously identify predator and

prey species (McCormick and Polis, *op. cit.*). We found no literature concerning such interactions for Atlantic forest species.

Submitted by **LUIS CESAR SCHIESARI, FLORA ACUÑA JUNCÁ** and **GUSTAVO DE MATTOS ACCACIO,** Departamento de Zoologia, Instituto de Biociências, Universidade de São Paulo, 20520, 01452-990, São Paulo-SP, Brazil.

LEPTODACTYLUS ALBILABRIS (Caribbean White-lipped Frog). **LARVAL DIET**. *Leptodactylus albilabris* is a common frog throughout Puerto Rico. It produces foam nests and its tadpoles occur in a variety of still and slowly flowing waters (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies, Descriptions, Distributions, and Natural History. Univ. of Florida Press, Gainesville. 720 pp.). Little is known of the larval biology of this species and nothing has been reported of the dietary habits of the tadpoles. On 19 May 1994, we observed *L. albilabris* tadpoles of sizes from approximately 6 mm (newly emerged from a nearby foam nest) to 13 mm in a shallow (<5 cm deep) stream at the bottom of a steep ravine in relatively undisturbed wet forest at an elevation of 700 m in the Reserva Forestal Carite (Guavate), Sierra de Cayey, Commonwealth of Puerto Rico (66°02'30"N, 18°05'45"W). Larger tadpoles in two separate pools in the stream were feeding. In one pool larvae were feeding on a dead earthworm (length ca. 100 mm). In the other they were removing flesh from the nearly fully skeletonized carcass of an anole (estimated intact SVL 60 mm). Features of the lizard's skull were consistent with those of *Anolis gundlachi*, which was abundant in the vegetation surrounding the stream. The only other anole observed near the stream was *A. evermanni*. Although few tadpole species are obligate carnivores (Bragg 1965. Gnomes of the Night, the Spadefoot Toads. Univ. of Pennsylvania Press, Philadelphia. 127 pp.), facultative carnivory is more widespread and can occur in species showing no obvious morphological feeding specializations (Heyer et al. 1975. Biotropica 7:100–111). Documentation of tadpole predation or scavenging on vertebrates is rare, but *Leptodactylus pentadactylus* preys on the tadpoles of other anurans (Heyer et al., *op. cit.*; Kluge 1981. Misc. Publ. Mus. Zool. Univ. Michigan 160:1–170). Scavenging of terrestrial vertebrates by larvae is less well-documented, but *Lechriodus fletcheri* tadpoles have been observed to feed on adults of the same species (Martin 1967. Aust. Nat. Hist. 15:326–330). Although the observation of scavenging on a terrestrial vertebrate carcass by *Leptodactylus albilabris* tadpoles is an isolated event, it suggests that facultative carnivory may be more widespread among members of the genus *Leptodactylus* than previously recognized. Further, it highlights the dietary plasticity and opportunistic feeding behavior capable by relatively generalized tadpoles.

Submitted by **RICARDO LEBRON, A. TINA BATRA, JAMES BONTEMPO, CHRISTIAN BUCKLEY, MITCHELL CRON, LINDA FENSTERMACHER, CHRISTINA MAHONEY, LAURA SCHMITT,** and **AARON M. BAUER**, Biology Department, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA.

PELTOPHRYNE GUENTHERI (NCN). **PARASITISM**. In the course of a dietary study of the endemic Hispaniolan toad, *Peltophryne guentheri*, we examined the stomach contents of 204 specimens. In three adult males from different sites in Haiti (Arbonite, near Los Poteaux) and the Dominican Republic (Independencia, near Lago Enriquillo; Monte Cristi, near Copey), we found immature nematodes (*Skrjabinoptera* sp., Physalopteroidea) admixed with ingesta. Prevalence was 1.5% (3 of 204 specimens examined). Intensities ranged from 1–4 (mean = 2.0) parasites per host. Total lengths of nematodes ranged from 1.7–2.4 mm (mean = 1.93 mm), maximum diameter from 14–15 μ (mean = 14.3 μ).

Skrjabinoptera has not been found previously in any amphibian (Baker 1987, Mem. Univ. Newfoundland Occ. Pap. Biol. No. 11), but *S. leiocephalorum* has been found in Hispaniolan lizard hosts. This parasite was originally described from *Leiocephalus schreibersii* and *L. barahonensis* (Greve and Powell 1989, J. Parasitol. 75:677–679; Powell et al. 1990, J. Helminthol. Soc. Washington 57:75–77). Powell et al. (1990. Herpetol. Rev. 21:60–61) noted its occurrence in *L. semilineatus*. Fobes et al. (1992. Carib. J. Sci. 28:200–207) and Moster et al. (1992. Bull. Maryland Herpetol. Soc. 28:150–161) found *S. leiocephalorum* in *Anolis cybotes* and *A. brevirostris*, respectively. That so many diverse lizards support this parasite suggests that a common prey item is the vector (probably one or more species of insect). *Peltophryne guentheri* may feed on the same prey. However, the low prevalence and the fact that all parasites were juveniles may reflect the inadequacy of *P. guentheri* as a final host.

PSEUDACRIS REGILLA (Pacific Chorus Frog). **REPRODUCTION**. On 28 and 29 August 1993, I observed *Pseudacris regilla* tadpoles in weakly brackish (~1.0%) ('brackish' sensu Remane and Schlieper 1971. Biology of Brackish Water. Wiley, New York. 327 pp.) supratidal pools on Frank Island and at South Beach, west-central Vancouver Island, British Columbia, Canada. Some inland populations of *P. regilla* frequent and presumably breed in brackish water (Brues 1928. Proc. Am. Acad. Arts Sci. 63:138–228; Brues 1932. Ibid. 67:184–303; Murray 1958. Herpetologica 11:33–48), but reproduction in brackish supratidal pools has not previously been reported. The Vancouver Island breeding pools appear similar to those used by *Bufo calamita* in Sweden (Andrén and Nilson 1985. Amphibia-Reptilia 6:137–142): pools are small (<3 m^2), shallow (<45 cm), and not connected to the ocean. At high tide they are no higher than 4 m above sea level and as close as 5 m to the water's edge. Salt spray and inundation of sea water during storms apparently adds salt water to these pools, but heavy rainfalls and surface runoff probably maintain salinities at dilute levels.

Although at least seven other amphibian species are sympatric with *Pseudacris regilla* across west-central Vancouver Island (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Press of Idaho, Moscow. 332 pp.), I found only *P. regilla* tadpoles and aquatic arthropods in the supratidal pools. Tadpoles ranged in density from one to about 25 individuals per pool and stages 28 to 42 of Gosner (1960. Herpetologica 16:183–190). The late stage larvae suggest that metamorphosis successfully occurs; however, I failed to locate any metamorphosed frogs. I deposited seven voucher tadpoles from Frank Island in the University of Alberta Museum of Zoology (UAMZ 3001), Edmonton, Alberta.

I thank Josie Cleland (Clayoquot Biosphere Project, Tofino) for bringing the Frank Island tadpole pools to my attention, Dick Pereschitz for conveying a relevant paper, Gertie Hutchinson (Univ. Alberta) for salinity testing, and my wife, Joan Marklund, for tolerating my field studies while we were vacationing.

PSEUDACRIS STRECKERI ILLINOENSIS (Illinois Chorus Frog). **BURROWS**. The fossorial chorus frogs *Pseudacris ornata* and *P. streckeri illinoensis* both use their forelimbs to burrow in the substrate (Brown et al. 1972. Herpetologica 28:325–328; Brown and Means 1984. Amphibia-Reptilia 5:261–273). Forward burrowing is unusual: most fossorial frogs dig backwards with their hind feet (Brown and Means, *op. cit.*). In *P. streckeri* this behavior is associated with subterranean feeding (Brown 1978. Herpetologica 34:212–216), and in both species with reduction of the intercalary phalanges in the forelimbs (Paukstis and Brown 1987. Brimleyana 13:55-61; Paukstis and Brown 1991. Can. J. Zool. 69:1297–1301). Few details about the burrows of free ranging chorus frogs of either species are available (Axtell and Haskell 1977. Nat. Hist. Misc. 202:1–8). We herein document the construction of burrows by newly transformed *P. s. illinoensis*, and add a further record of a burrow occupied by an adult male frog.

We observed a population of *P. s. illinoensis* in Madison County, Illinois (4.8 km SW Edwardsville, T4N, R9W, sec. 29). Soils in this area are Oakville fine sand and Bloomfield loamy fine sand (Goddard and Sabata 1986. Soil survey of Madison County, Illinois. U. S. Dept. Agriculture, Soil Conservation Service, U. S. Government Printing Office, Washington, D. C., 254 pp.), and are consistent with soils used by *P. s. illinoensis* from the lower Illinois River (Brown and Rose 1988. Illinois Nat. Hist. Surv. Biol. Notes 132:1-13).

On 20 April 1993 at 2230 h we dug one adult male (35 mm SVL) from a burrow 2.9 m from a breeding pond. This burrow was 45 cm long and 11 cm below the soil surface at its terminus. It appeared to be level with depth being produced by its location on a slope. The opening was semi-oval in shape (2.2 cm wide and 1.4 cm high) with a loose sand apron. Apparently, the loose sand was pushed from the burrow. The terminus consisted of a slightly enlarged chamber with damp but not saturated sand. The frog was well hydrated and active. We heard no calling from the vicinity of the burrow. Underground calling has been reported for *P. ornata* (Brown and Means, *op. cit.*).

The burrow was in an area of unvegetated sand. We excavated similar burrows (38), but found no other frogs. No excavated burrows were within 5 cm of plants. Some burrows could have been made by toads; choruses of *Bufo americanus* and *B. woodhousii fowleri* were present. Three male *B. americanus* were also dug from two burrows the same night. The larger burrows occupied by toads differed from the burrow made by the chorus frog in that their openings were circular with sand pushed up all around the margin of the opening. Toad burrows also dipped at a steeper angle. One toad burrow was 18 cm long and 12 cm deep; the other was 20 cm long and 10 cm deep.

Axtell and Haskell (*op. cit.*) reported that burrows of *P. s. illinoensis* dipped at a steep angle (20 cm depth with 10 cm lateral displacement) or were nearly vertical (2 of 3 burrows). The openings of those three burrows were similar to the one that we observed. The depths of the four (3 from Axtell and Haskell and one we report) known burrows of *P. s. illinoensis* averaged 15.2 cm (range 11–20 cm). Axtell and Haskell (*op. cit.* p. 2) also noted that burrows containing frogs were located in areas devoid of vegetation. These details are important because excavation of likely-looking burrows in vegetation-free areas in suitable sandy habitats is a useful method for locating specimens of the highly secretive *P. s. illinoensis* both at choruses (our record) and away from breeding sites (Axtell and Haskell's report).

Between 24 May and 12 June while conducting a survey of the site for transforming chorus frogs, 42 burrows containing newly transformed froglets were excavated in a wheat field near the natal pond. Twenty-three of these were in bare sand, but 19 were within 0.5 cm of wheat plants. No burrows were in heavy vegetation at the margins of the wheat field or between the wheat field and natal pond. Most burrows were less than 2 cm long (mean =

3.8 cm, range 1.2–15 cm, N = 22) and shallow, but one was 15.0 cm long and 4 cm deep at its terminus. Many froglets were seen at the mouth of burrows. When we approached, froglets usually fled by hopping into the open rather than into the burrow. All burrows were excavated during daylight and may have been temporary refuges constructed to avoid desiccation during a post-transformation migration.

Burrows containing either adult or newly transforming frogs were not found in heavy vegetation. Our observations support the hypothesis that sod or compacted soils are incompatible with the frog's burrowing life history (see Brown et al., *op. cit.*; Axtell and Haskell, *op. cit.*). If these contentions are true, vegetation in habitats used by *P. s. illinoensis* should be managed to prevent thickening or sod formation. Compaction of sandy soils by human or natural means may be detrimental to the persistence of the frog.

We thank K. Brockmeier, Brockmeier Sod Farms, for allowing unrestricted access to his property to conduct this study. L. E. Brown, D. Moll, G. L. Paukstis, and G. B. Rose read drafts of this paper. C. H. Theiling allowed us to use Long Term Resource Monitoring program facilities. G. Kruse expedited the granting of permits necessary for this research. This research was supported by Illinois Department of Transportation contract 1-5-90179 with the Illinois Natural History Survey, J. K. Tucker and D. P. Philipp, Co-Principal Investigators.

RANA CATESBEIANA (Bullfrog). **DIET**. True toads (Bufonidae) are infrequently reported in the diet of *Rana catesbeiana* (see review by Bury and Whelan 1984. U.S. Dept. Interior Fish and Wildlife Serv. Res. Pub. 155). On 31 July 1992 (2100 h), I collected two adult female bullfrogs (180 mm and 156 mm SVL, respectively) in a temporary roadside pool formed by overflow from a permanent irrigation pond, 12 km ESE of Hermanas, Luna County, New Mexico. Chorusing males of *Scaphiopus couchii*, *Spea multiplicata*, *Bufo cognatus*, *B. debilis*, and *Gastrophryne olivacea* were also present in this or nearby pools. The stomach of the larger bullfrog contained a *B. cognatus* (70 mm SVL), a *B. debilis* (42 mm SVL), and two tenebrionid beetles. The second frog had eaten an anuran, a mouse (both unidentifiable), a centipede (*Scolopendra* sp.), and several beetles. The *B. debilis* had been only recently ingested, whereas the *B. cognatus* probably had been eaten the previous night as it was partially digested.

Brown (1974. Southwest. Nat. 19:335–336), and Tucker and Sullivan (1975. Trans. Illinois State Acad. Sci. 68:167) noted that *Bufo* are apparently unpalatable to bullfrogs due to their toxic parotoid gland secretions which may cause regurgitation of the prey item or even immobilization of the predator. I shot both bullfrogs and therefore could not determine if the larger specimen exhibited symptoms of poisoning. It is noteworthy, however, that this frog, perhaps due to its large body mass, was able to consume the *B. debilis* after ingesting and partially digesting the *B. cognatus*. Similar observations of ingestion and digestion of *Bufo valliceps* by bullfrogs were reported recently by Platt and Fontenot (1993. Bull. Chicago Herpetol. Soc. 28:189–190).

The bullfrogs were collected under permit from the New Mexico Department of Game and Fish and are deposited (with stomach contents) in the Museum of Southwestern Biology, University of New Mexico (MSB 54999-55000). I thank W. G. Degenhardt, R. D. Jennings, and C. W. Painter for comments.

Submitted by **JAMES N. STUART**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

RANA TEMPORALIS (Golden Frog). **ECOLOGY**. Five adult (SVL 35.0–73.5 mm; mean = 53.80 ± SE 7.36 mm) *Rana temporalis* (Günther 1864) were collected 28 August 1990, from a forest in the vicinity of Tirunelveli (8° 25'-35' N, 77° 25'-35' E), Tamil Nadu State, India. The frogs were found on boulders along an intermittent stream bed. Two were males with enlarged testes (SVL 41.6 and 51.4 mm) and three were females with developed ovaries (SVL 67.5, 35.0 and 73.5 mm). Two of the females were gravid, one with SVL 67.5 mm contained 838 eggs (1.81% of body weight; mean = 0.07 mm, N = 3), another SVL 73.5 mm contained 1225 eggs (7.38% of body weight; mean = 0.14, N = 3).

Little data are available on the diet of this species. Abdulali (1962. J. Bombay Nat. Hist. Soc. 59:228–237) found three frogs, including a *Rana limnocharis*, in the stomachs of two *R. temporalis*. These *R. temporalis* contained food in their stomachs, constituting 0.20–1.46%, respectively, of the total body weight. A total of ten prey items were recovered from the five frogs reported here. Prey length ranged between 1.60–7.90 (mean = 4.66 ± SE 1.01) mm, and included two dipterans (including a stalk-eyed fly), two spiders, two cockroaches, two termites, and two unidentifled insects (one with eggs). The average number of prey items was 2 (SE 0.45, range 1–3 items).

TESTUDINES

CHRYSEMYS PICTA BELLI (Western Painted Turtle). **FEEDING BEHAVIOR**. *Chrysemys picta* is typically omnivorous (e.g., Ernst and Barbour 1989. Turtles of the World. Smithsonian Institution Press, Washington, D.C., 313 pp.; Raney and Lachner 1942. Copeia 1942:83–85). Although there is anecdotal information concerning painted turtles feeding on crustacean zooplankton (e.g., Brown 1992. J. Elisha Mitchell Sci. Soc. 108:38–54), the importance of zooplankton to turtle diets is poorly known (Knight and Gibbons 1968. Amer. Midl. Nat. 80:558–562; MacCulloch and Secoy 1983. Can. Jour. Zool. 61:1499–1509). This report examines the behavior of juvenile *C. p. belli* feeding on cladoceran zooplankton.

A juvenile *C. p. belli* (60 mm plastron length) was collected on 9 April 1993 while it was basking on a log in the littoral zone of Lone Star Lake (a 79 ha reservoir 20 km from Lawrence, Douglas Co., Kansas). The turtle was brought back to the laboratory, placed in a 19 L aquarium filled to a depth of 15 cm, and left overnight. A student placed a mixture of zooplankton in the aquaria and noticed that the turtle began to feed immediately. On 17 April 1993, I conducted an experiment to look at feeding behavior. After withholding food for 24 h, I placed 50 lab-cultured Daphnia magna (2–2.5 mm) in the aquarium (density = 5/L; water temperature = 20.5°C). I then observed the turtle for 5 min and counted the number of attacks and the number of successful attacks. Ten minutes after the trial was completed, I added 15 additional prey items of the same size to estimate the distance at which the turtle could locate *Daphnia*.

The turtle reacted immediately to the presence of prey, and attacked 39 *Daphnia* during the 5 min trial with a capture success of 92% (feeding rate = 7.2/min). During a typical feeding sequence, the turtle located a *Daphnia* while swimming underwater, oriented toward it, swam to within ca. 2 cm, retracted the head, and immediately lunged the head forward (termed a "head-lunge" by Brown, op. cit.) to capture the prey. The mean distance at which the turtle located *Daphnia* was 10 cm (range 4–11.5 cm). The turtle was released at the site of capture on 18 April 1993. I thank Thomas Berendonk for his initial observations.

ERETMOCHELYS IMBRICATA (Hawksbill). **PREDATION**. Records of shark predation on sea turtles are scarce, especially on the hawksbill (Witzell 1983. FAO Fish. Sinop. 137, Rome, 77 pp.). In the tropical eastern Atlantic Ocean the tiger shark, *Galeocerdo cuvier*, is a major predator on hawksbills (Cadenat 1977. Inst. Fr. Afr. Noire 19 (1):274–294). Here we report on a hawksbill eaten by a tiger shark in the western Atlantic Ocean, between Nova Viçosa and the Parcel de Abrolhos (18° 00' S, 39° 02' W), Bahia, eastern Brazil. On 2 March 1994 a whole juvenile hawksbill with carapace 34 cm long and 27 cm wide (curved measurements) was found by fishermen in the stomach of a shark with body mass 120 kg (estimated total length 250 cm, diameter of the jaws 31 cm) caught near reefs at a depth of about 15-20 m. The Nova Viçosa fishermen informed us that they frequently find sea turtles in the stomachs of tiger sharks. Predation on hawksbills by tiger sharks may be common, since both the turtle and the shark are associated with reefs and shallows (Böhlke and Chaplin 1968. Fishes of the Bahamas and adjacent Tropical Waters, Livingston Publ., Wynnewood, 771 pp.; Witzell, *op. cit.*). The turtle carapace and pieces of the shark jaws are deposited at the Museu de História Natural, Universidade Estadual de Campinas (ZUEC 1693 and 1960).

We thank I. Verjovsky, A. Batalha, and P. Bonino for introducing us to the fishermen of Nova Viçosa, G. de Jesus for information on tiger sharks, M. Martins for comments on the manuscript, and the CNPq for financial support.

HYDROMEDUSA MAXIMILIANI (Maximilian's Snake-necked Turtle). **JUVENILE MORPHOLOGY**. *Hydromedusa maximiliani* occurs in southeastern Brazil, from Espírito Santo to São Paulo (Ernst and Barbour 1989. Turtles of the World. Smithsonian Institution Press, Washington, D.C. 313 pp), living in shallow streams inside rain forests in mountainous regions. Although adults have been described in detail (Ernst and Barbour, *op. cit.*) there is no information on hatchling or juvenile morphology of this species.

From June to December 1993, several specimens (hatchlings, juveniles and adults) of *H. maximiliani* were observed and measured in the wild at Carlos Botelho State Reserve, São Paulo (24° 03' S; 47° 59' W). The mean carapace length of hatchlings and juveniles was 89.7 mm (N = 33; SD = 20.7 mm; range = 47.3–122.5 mm) and their mean mass was 78.2 g (N = 33; SD = 40.6 g; range = 15.0–160.5 g). Adult carapace length was 160.1 mm on average (N = 52; SD = 17.9 mm; range = 129.0–197.5 mm). The plastron color of hatchlings and juveniles was either completely dark with a yellowish bridge or yellowish with peripheral dark spots. The carapace was uniformly brown or dark gray, with the lower border of marginal scutes yellowish, with black sutures in some animals. Maxilla and mandible were blackish or yellowish (in adults, jaws are cream to yellow). The iris was black in all individuals. Dorsal and lateral parts of the head and neck and dorsal side of the limbs were brown or olive gray; ventral side of the limbs was yellowish or cream colored, similar to adults.

The main feature of the carapace morphology in juveniles is the marginal scutes, which from the seventh scutes posteriorly makes a serriform shape of the carapace rim. This characteristic disappears as the animal grows. None of the traits that exhibit sexual dimorphism in adults (Guix et al. 1992. Bol. Asoc. Herpetol. Esp. 3:23–25) was found to differ between male and female juveniles.

I thank to Dr. Bento V. M. Neto and Instituto Florestal for logistical support, Dr. A. S. Abe and an anonymous reviewer for commenting on the manuscript, and CNPq (grant 132400/93-6).

HYDROMEDUSA TECTIFERA (South American Snake-necked Turtle). **PREDATION**. On 12 November 1990, I observed a giant otter, *Pteronura brasiliensis* eating an adult (25 cm carapace length) *Hydromedusa tectifera*. The animals were in a 10 X 15 m, 3 m deep pool formed by a moderately fast-flowing, 10 m wide

river located inside Tropical Atlantic Forest in southern São Paulo State, Brazil (25°03'S, 48°04'W), elevation 150 m. The otter held the turtle with its paws, keeping itself partly in the pool, while biting the anterior part of the turtle's carapace mainly around its borders. Upon detecting me, the otter left the carcass and disappeared. The turtle's head, neck and legs had been eaten. About 1.5 km downstream I found a turtle plastron 15 cm long which had been gnawed by an otter. There is no published information on the natural enemies of eastern Brazil *Hydromedusa* (Ernst and Barbour 1989. Turtles of the World. Smithsonian Inst. Press, Washington, D.C., 313 pp.). The rare giant otter has been observed, in the Atlantic Forest, to disturb dead leaves which accumulate at the bends of rivers, a favorite habitat for *H. tectifera* (pers. obs.). These observations suggest that otters may be an important predator of *H. tectifera* in southeastern Brazil.

I thank F. Olmos for comments on the first draft of the manuscript.

LACERTILIA

CARLIA* CF. *FUSCA (NCN). **BEHAVIOR.** Although introduced *Carlia* cf. *fusca* (hereafter referred to as *Carlia*) has been implicated as a causal factor in declines of native scincids on Guam, Mariana Islands (Case and Bolger 1991. Evol. Ecol. 5:272–290; McCoid 1993. Herpetol. Rev. 24:1–17; Rodda and Fritts 1992. J. Herpetol. 26:166–174; Rodda et al. 1991. Micronesica 24:195–210), few corroborative data exist. Rodda and Fritts (*op. cit.*) presented retrospective museum data indicating a decline in native scincids while *Carlia* exhibited a reciprocal increase. These data, coupled with field observations, led these investigators to label *Carlia* as an aggressive kleptoparasite that displaced native scincids. It was routinely observed that *Carlia* would approach *Emoia caeruleocauda* that were foraging and either directly steal food or displace them from a foraging area. Herein, I provide additional observations and suggest that *Carlia* is also displacing native scincids by overt aggression and predation.

The most common native scincid on Guam is *Emoia caeruleocauda*; its distribution was probably island-wide at one time. Habitats with the current highest densities are primary and secondary forests, although enclaves of *E. caeruleocauda* can be found throughout the island in association with reasonably lush patio gardens and relict forest patches. In contrast, *Carlia* is now the most abundant scincid on Guam and is common in all habitats, including highly urbanized areas. *Emoia caeruleocauda* on Guam reaches a maximum SVL and mass of 54 mm, 3.3 g, while *Carlia* is longer and more robust (65 mm SVL, 6.3 g).

While trapping *Boiga irregularis* (brown tree snakes) on Guam (1989–1990), G. Rodda and I noticed that when adult *Hemidactylus frenatus* used as bait were released, they were frequently attacked by *Carlia*. On many other occasions, *Carlia* was observed on the forest floor chasing *E. caeruleocauda* for at least several meters. Often, *E. caeruleocauda* would escape *Carlia* by climbing vegetation where *Carlia* would rarely pursue higher than 1 m. On Guam, *E. caeruleocauda* appears to be more arboreal than on islands that lack *Carlia* (e.g., Rota, Mariana Islands) (pers. obs.). While using 'sticky traps' to collect lizards (Rodda et al. 1993. Herpetol. Rev. 24:99–100), I retrieved adult *Carlia* from traps with subadult *E. caeruleocauda* in their jaws on at least three occasions. It is likely the *Carlia* were attracted to the trapped skinks. On three occasions, the approach of an *E. caeruleocauda* to a *Carlia* in a basking site elicited a chase by the *Carlia*. In all three instances, the approaching *E. caeruleocauda* head-bobbed at a *Carlia* less than 1 m distant. The *Carlia* then head-bobbed and pursued. Despite being larger and heavier, size of the *Carlia* may not be important in agonistic interactions; a subadult *Carlia* (ca. 40 mm SVL) was observed chasing an adult male *E. caeruleocauda* (ca. 50 mm SVL). *Carlia* has also been seen to pursue, capture, and break off and devour a tail of an *E. caeruleocauda*. Pursuit of *Carlia* by *Emoia* has never been observed on Guam.

Recently, Petran et al. (1993. Science 259:354–358) concluded that behavioral exclusion by *Hemidactylus frenatus* affected local distributions of the native *Lepidodactylus lugubris*. McCoid and Hensley (1993. Herpetol. Rev. 24:87–88) augmented this portrait, using the same species, with observations of predation. It seems likely that local distributions of native scincids on Guam are being affected by introduced *Carlia* through similar competitive mechanisms. Behavioral exclusion, aggression, and predation on native scincids by *Carlia* probably all are important in altering the distribution of *E. caeruleocauda* on Guam.

Portions of this study were supported by the Endangered Species Conservation Program, Project E4. Rebecca Hensley kindly reviewed a version of this manuscript.

GALLOTIA GALLOTI (Canary Islands Lizard). **NECTAR FEEDING.** All four species of *Gallotia* (Lacertidae) currently living in the Canary Islands have been reported to eat a substantial amount of vegetable food (Kreffl 1950. Zool. Anz. 145(Suppl.):426–444; Molina-Borja 1991. Vieraea 20:1–9; Molina-Borja and Barquin 1986. Vieraea 16:233–236; Naranjo et al. 1991. Rev. Esp. Herp. 6:45–48). Plant parts consumed include leaves, flowers, flower buds, fruits and seeds, but there are no published accounts of any *Gallotia* feeding on nectar. In fact, observations of nectarivory in lizards are scarce and only a handful of species, mostly geckos, are known to regularly visit flowers to feed on nectar (Whitaker 1987. N. Z. J. Bot. 25:315–328). Here we report observations of nectar feeding in *G. galloti*, a medium-size lacertid (145 mm maximum SVL) inhabiting the westernmost islands of the Canarian archipelago (Barbadillo 1987. La Guia de Incafo de los Anfibios y Reptiles de la Peninsula Iberica, Islas Baleares y Canarias. Incafo, Madrid, 694 pp.).

Observations were conducted in Loro Parque, a privately owned zoological park located in the Punta Brava district of Puerto de la Cruz (Tenerife, Canary Islands). *Gallotia galloti* occur at relatively high densities throughout the park, but they are most conspicuous alongside the walkways in plots dominated by cacti and palm trees (*Phoenix* sp.), with no ground cover. The lizards are relatively undisturbed and tolerate close-range inspection by an observer. Adult *G. galloti* were seen carrying dates and other fruit in their mouths and occasionally picking up handouts provided by the visitors. Between 1400 and 1500 h on 23 August 1992 we noticed several *G. galloti* climbing through a hedgerow of crown of thorns (*Euphorbia milii* (= *E. splendens*), Euphorbiaceae), a thorned, woody-stemmed spurge from Madagascar. As many as five lizards were observed clinging to the shrubs, some ca. 50 cm from the

ground, sequentially lapping the nectar from several flowers. All the lizards foraging for nectar were juveniles; the dense branching and the sharp thorns may limit access to the flowers to all but the smallest individuals. Although *E. milii* is an exotic ornamental, the Canarian flora is rich in indigenous Euphorbiaceae that may be exploited as a natural source of nectar. Previous reports described adults of *G. galloti* feeding on leaves and flowers of *Euphorbia balsamifera* (Molina-Borja 1981. Doñana, Acta Vertebrata 8:43–78), adult *G. stehlini* from the island of Gran Canaria eating buds of *E. obtusifolia* and dry leaves of *Ricinus comunis* (Molina-Borja 1986. Vieraea 16:23–26), and juvenile *G. simonyi* from El Hierro Island taking flowers of *E. obtusifolia* (Machado 1985. Bonn. Zool. Beitr. 36:429–470).

Most observations of lizard nectarivory have occurred on islands (e.g., geckos: Whitaker, *op. cit.*; *Cnemidophorus murinus:* Dearing 1993. J. Herpetol. 27:111–114). Among lacertids, nectar feeding has been described in *Podarcis dugesii*, the Madeiran lizard (Elvers 1978. Botaniska Notiser 131:159–160), and *P. lilfordi* from Nitge (Menorca, Balearic Islands) (Brown et al. 1992. Oecologia 91:500–504). This note documents nectar feeding in another insular lizard species and reiterates the ability of *Gallotia galloti* to exploit a variety of food sources. We thank Matt Kramer, Statistical Research Division, U.S. Bureau of the Census, for his comments on this manuscript.

KENTROPYX ALTAMAZONICA (NCN). **COLOR**. Museu de Zoologia da Universidade de São Paulo, numbers 57891-57892. The "*calcarata*" group within the teiid genus *Kentropyx* have bright green stripes on the head and forebody at hatching which gradually become fainter with age. Adults are patterned with shades of brown, black, or grey which camouflage them among leaf litter (*K. calcarata* and *K. pelviceps*) or muddy river banks (*K. altamazonica*). In contrast, *K. striata*, which occurs in savannas and islands on the lower reaches of the Amazon River, has bright green coloration along the posterior dorsal surface of the body (Gallagher and Dixon 1992. Bolletin Museo regionale di Scienze naturali-Torino 10(1):125–171). Here we report the color of *K. altamazonica* which were encountered in flooded grasslands on islands in the central part of the Amazon River near Manaus Amazonas, Brazil (3°05'S, 60°00'W). At least 4 lizards were seen 16 June 1981 and two were shot with an air rifle and one was photographed to allow an accurate description of its color. The adult male had a brownish grey head with a faint green mid-dorsal stripe. Its flanks were grey with faint blue-green blotches. A rich brown dorsolateral stripe commencing at the hind legs broke up into large black blotches at mid-body and faded out so that it was barely distinguishable at the level of the forelimbs. Its extension to the eye was only discernable from tiny black irregularly distributed black blotches and a faint green stripe along its lower edge. The dorsal surface of the hindlimbs was brown with white blotches. The dorsal surface of the body lacked stripes and blotches. The nape of the neck was sky blue, becoming lime green at the level of the forelimbs. The lime green extended onto the tail about as far as the knee reaches when the hindlimb is extended backwards. The rest of the tail was light brown.

Scalation indicated that the lizard was definitely a *K. altamazonica* or, if a new cryptic species, at least a member of the "*calcarata*" species group. The sky blue on the nape of the neck has no equivalent among other species of *Kentropyx* but the generally uniform green dorsal surface is much more similar to that of *K. striata* than other members of the "*calcarata*" group. We speculate that the occupation of islands with flooded grassland habitat has resulted in color convergence between some populations of *K. altamazonica* and *K. striata*.

Submitted by **WILLIAM E. MAGNUSSON** and **ALBERTINA P. LIMA**, Departamento de Ecologia, Instituto Nacional de Pesquisas da Amazônia, CP 478, 69011-970 Manaus AM, Brazil.

PSAMMODROMUS ALGIRUS (Large Psammodromus). **PHONOTAXIS**. *Psammodromus algirus* is distributed throughout Iberia and parts of south western France. It is a medium-sized lacertid (8 cm SVL) with a robust body and large head (Arnold and Burton 1978. A Field Guide to the Reptiles and Amphibians of Britain and Europe. Collins, London, 272 pp.).

Seven adult male *P. algirus* were released into an enclosure at the Museo de Ciencias Naturales Field Station at El Ventorrillo, Madrid province (1000 m above sea level) in the Sierra de Guadarrama, central Spain. This enclosure was 65 m^2 and contained vegetation typical of the area (brooms; *Cytisus scoparius*, *Genista florida* and 'jara,' *Cistus laurifolius*) and in all respects reflected a normal habitat for *P. algirus*. These lizards are known to eat a wide variety of insects (Salvador 1985. Guia de Campo de los Anfibios y Reptiles de la Peninsula Iberica, Islas Baleares y Canarias. Unigraf, Madrid, 212 pp.) and I observed them eating two of the commoner species of orthopterans found at the site: *Oedipoda caerulescens* (Acrididae) and *Steropleurus stali* (Tettigoniidae). *S. stali* is a plump, flightless bushcricket about 2.5 cm long. The song of a male *S. stali* is a chirp of 252–305 ms duration with a frequency of 9700 Hz (Hartley et al. 1974. Anim. Behav. 22:382–389). The sound pressure level is about 70 dB at one meter and there is an inter-chirp interval of four to eight seconds (Bateman, unpubl.).

The following experiments were done on successive days in September 1993. All trials were carried out twice. 1) A recorded song of a male *S. stali* was played from a speaker situated in the center of the enclosure at ground level. 2) The song was played from the center of a bush approximately 30 cm above the ground. 3) This experiment was the same as experiment 1 except that a clear plastic container with four non-calling female *S. stali* was placed on top of the speaker. 4) This experiment was the same as experiment 2 except that a clear plastic container with four non-calling female *S. stali* was placed on top of the speaker. 5) The plastic container with the females (silent) was placed on the ground without the speaker. 6) Finally, three singing males were put in a small gauze box placed at ground level. In all cases speaker and/or bushcrickets were left for 30–40 minutes and if no reaction by the lizards was noted in that time the trial was terminated.

In experiments 1, 2, 3, and 4 there was a positive reaction to both trials. A male *P. algirus* was observed circling in towards the speaker when it was at ground level and circling in towards the base of the bush when the speaker was playing from above ground. The movement of these lizards appeared to be quite different from their behavior at other times when they were mostly making short runs into, or out of, shade. The lizard approached the speaker with the female bushcrickets on it more closely (within 10 cm) than the speaker without the bushcrickets (>20 cm). There was no reaction

to experiment 5 with the silent females and there was a single reaction to experiment 6 when a male again circled the gauze box and approached to within 10 cm before retreating again.

Several studies show that acoustic signallers run the risk of exposing themselves to predators, including calling gryllid crickets being hunted by herons (Bell 1979. New York Ent. Soc. 87(2):126–127) and calling tropical bushcrickets being hunted by bats (Belwood and Morris 1987. Science 238:64–67). In Britain the frequency range of the call of the bushcricket *Leptophyes punctatissima* overlaps that of shrews (Soricidae) and four species of foliage-gleaning bats and thus all are potential predators (Robinson 1990. *In* W. J. Bailey and D. C. F. Rentz (eds.), The Tettigoniidae: Biology, Systematics and Evolution, pp. 112–119. Crawford House Press, Bathurst).

These experiments demonstrated that an acoustic signal from a *Steropleurus* is evidently used by eavesdropping *P. algirus*. *Psammodromus algirus*, therefore, appear to use auditory cues in hunting acoustic prey, and may also use visual or olfactory cues at closer range.

I thank the directors of the El Ventorrillo Field Station, Drs. Alfredo Salvador, Luisma Carrascal, and Eulalia Moreno.

Submitted by **PHILIP W. BATEMAN**, Animal Behaviour Research Group, Department of Biology, The Open University, Walton Hall, Milton Keynes, MK7 6AA, U.K.

TUPINAMBIS TEGUIXIN (Tegu Lizard). **AQUATIC BEHAVIOR.** On 5 November 1993, while snorkeling in search of freshwater fish in a mountain creek pool about 300 m elevation at Ilhabela State Park, São Sebastião Island, Brazil (23°50'S, 45°20'W), I discovered a sleeping *Tupinambis teguixin sebastiani* Müller 1968 (Die Herpetofauna der Insel von São Sebastião, Saarbrucken Zeitung Verlag u. Druckrei Gmb H., 68 pp.) about 1 m TL and 30 cm SVL, on the bottom of the pool, 1.8 m deep. The lizard lacked the enlarged neck typical of adult males and showed a bright, new skin. The pool was located in rugged terrain covered by old second-growth and primary Atlantic forest, and was fed by a clear water creek 4-6 m wide that ran over sand and rocks. The day was sunny with air temperatures between 25–30°C, and water temperature between 15–18°C.

After watching the lizard for 10 min, without it ever moving, I lightly pulled its tail, which caused it to open its eyes, stare at me for a while, and close them again. After another pull, the lizard walked toward a pile of dead leaves that accumulated on the otherwise sand and gravel bottom and partly buried itself. Moments later it walked along the bottom towards an emerging rock, which it climbed until its head was above the water. I avoided further disturbing the lizard, and after about 10 min of watching me, it dove towards a submersed rock 1.1 m deep and laid itself by the rock's side, closing its eyes and not moving for 12 min, when it again walked along the bottom and positioned itself under a rock 0.5 m under the water. After another 10 min, disturbed by my attempts of following and measuring it, the tegu dove to deeper waters, this time half walking, half swimming with lateral strokes of its tail, and I was unable to find it again.

Why a tegu, regarded as a terrestrial lizard, would choose to sleep underwater in a cold stream (despite using a wet suit I was shivering after half an hour in the water) has no easy explanation. Although it may be a strategy to evade predators, the many boulders on shore would also offer shelter. It seems unlikely that the lizard was just taking a break after searching for food, as the stream was notably poor on fish, crabs, and crayfish that could be prey for a tegu. Perhaps the cold water offered a thermally comfortable environment for the lizard, but as the area is entirely covered by humid forest, other opportunities for finding adequate microclimates were likely at hand.

Although my observations may be regarded only as an oddity (but see Achaval and Langguth 1976. Boletin Soc. Zool. Uruguay 2:107) I am aware of two instances of tegus being caught in gill nets set at sea near the rocky shores of São Sebastião Island.

SERPENTES

CROTALUS VIRIDIS (Western Rattlesnake). **PHENOLOGY.** Mating in spring is apparently infrequent for *Crotalus viridis*. Spring mating has been reported in *Crotalus v. oreganus* along the Pacific Coast (Fitch 1949. Amer. Midl. Nat. 41:513–579; Fitch and Glading 1947. California Fish and Game 33:103–123; Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed. Univ. California Press, Berkeley, 1533 pp.) and was assumed to occur in populations of *C. v. oreganus* in Idaho (Diller and Wallace 1984. Herpetologica 40:182–193). However, many investigations involving intensive observation of free-ranging snakes have described midsummer to early fall matings in most *C. viridis* subspecies (see Ernst 1992. Venomous Reptiles of North America, Smithsonian Institution Press, Washington. 236 pp.).

During an investigation of activity patterns and feeding habits of a population of *Crotalus viridis viridis* in the Nebraska Sand Hills (42°15'0"N, 101°07'3"W), males were observed accompanying females five times during the mid-summer to early autumn mating period. Male-male combat was observed once on 1 Au-

gust 1991. Field observations were not conducted between 17 May and 16 July 1991 .

A single episode of courtship was observed in the spring on 6 April 1991 (this was not an observation of "commonly occurring spring mating" as misquoted by Duvall et al. 1992. *In* J. A. Campbell and E. D. Brodie, Jr., (eds.), Biology of the Pitvipers, pp. 321–336, Selva, Tyler, Texas). The female snake measured 835 mm SVL and weighed 428 g while the male measured 730 mm SVL and weighed 338 g. This pair of snakes was found 1 m from a prairie dog (*Cynomys ludovicianus*) burrow, containing the sloughed skin of the courted female. Ten meters away another fresh slough, that of the courting male, was found in the entrance of another prairie dog burrow. Dorsal patterns of slough and snake were matched for positive identification. The position of the skins suggested that they were sloughed as the snakes exited the burrows. Several loops of the male's body fell over the female's body and his tail was curled under and around the female's tail effecting cloacal apposition. The male intensively courted the female for 3.25 h. Sequence and duration of male courtship behaviors were consistent with those described previously for western rattlesnakes (Ernst, *op. cit.*; Hayes 1986. J. Herpetol. 20:246–249). The female was quiescent throughout the period of observation and did not tongue-flick, although she did exhibit the tail-whipping behavior described previously by Hayes (*op. cit.*). The snakes were courting when discovered at 1600 h and continued until 1915 h (sunset), at which time both snakes were collected. The snakes were not copulating at the time of collection. Eversion of the male's hemipenes was not observed, nor was intromission positively determined nor excluded.

Taken as a whole these observations suggest that most mating activity in this population occurs from mid-summer to early fall, consistent with previously published descriptions of mating phenology in this subspecies. While the observation of spring courtship may represent a relatively unusual event in this population, it raises the possibility that mating may occur in the spring as well as the fall for some populations of prairie rattlesnakes. Additionally, this observation agrees with the hypothesis that ecdysis and release of pheromones signalling female sexual receptivity may be linked.

Financial support of this research was provided by the University of Nebraska at Omaha Department of Biology, the University of Nebraska Graduate Student Research Fund, and by Tom and Caroline Holycross.

Submitted by **ANDREW T. HOLYCROSS**, Department of Zoology, Arizona State University, Tempe, Arizona 85287-1501, USA.

DIADOPHIS PUNCTATUS MODESTUS (San Bernardino Ringneck Snake). **DIET**. In April, 1992, a single individual of *Diadophis punctatus modestus* was collected from under a small board just off Redlands Boulevard, 1.0 mile south of San Timoteo Canyon Road in northern Riverside County, California. Examination in the laboratory revealed the snake had consumed a single individual of *Anniella pulchra* (California legless lizard). The lizard was swallowed head-first and most of the anterior portion of the body (including the skull, cervical vertebrae, and perhaps 1 or 2 anterior trunk vertebrae) was digested. Extremely degraded fragments of the left dentary and one or two cervical vertebrae remained. The snake measured 288 mm SVL (360 mm total length), the lizard approximately 130 mm (total remaining length). Neither specimen was weighed. To our knowledge, *Diadophis* has not previously been reported to prey upon *Anniella*. Specimens are curated in the University of California Museum of Paleontology (*Diadophis*, UCMP 140630; *Anniella*, UCMP 140631).

Submitted by **CHRISTOPHER J. BELL**, Department of Integrative Biology and Museum of Paleontology, University of California, Berkeley, California 94720, USA, and **JAMES K. BOWDEN**, Division of Earth Sciences, San Bernardino County Museum, 2024 Orange Tree Lane, Redlands, California 92374, USA.

HIEROPHIS VIRIDIFLAVUS (Western Whip Snake). **COMMUNAL NESTING**. Seasonal aggregations are sometimes observed in viperid (Duvall et al. 1985. Natl. Geogr. Res. 1:80–111; Fitch 1960. Univ. Kansas Mus. Nat. Hist. Publ. 13:85–288; Fukada 1962. Bull. Kyoto Gakugei Univ. Ser. B Math. Nat. Sci. 20:12–19) and colubrid (Henderson et al. 1980. Milwaukee Publ. Mus. Contrib. Biol. Geol. 32:1–9; Swain and Smith 1978. J. Herpetol. 34:175–177) snakes. Aggregations often occur before parturition (i.e., birthing rookeries, see Duvall et al., *op. cit.*). Unfortunately, little is known about the number of individuals in aggregations nor the site fidelity of aggregations across years.

Here we document an aggregation of female *Hierophis viridiflavus* in central Italy. Observations occurred about 50 km N Rome, Oriolo Romano, Province of Viterbo, 450 m above sea level. The site was characterized by a partially dilapidated stony box (5.0 x 3.5 m) bordered by rich spiny vegetation (mainly *Rubus* sp.) and completely surrounded by cultivated fields. We initiated the study in September 1989 when we captured 23 newborn *H. viridiflavus* (18–22 cm total length) in an area of 50 m^2. We regularly surveyed this site during late June 1990, 1991, and 1992. This aggregation of newborn snakes was noteworthy because 1) this species is not commonly encountered in cultivated habitats at the study area, and 2) the number of neonate snakes was greater than could be produced by a single female. Female *H. viridiflavus* normally produce 3–7 eggs per year in this area.

In June 1990 we collected five gravid female *H. viridiflavus* (Table 1). Snakes were measured (total length), marked (using scale clip procedures described in Brown and Parker 1976. J. Herpetol. 10:247–249), radiographed to obtain clutch size information, and released at the site of capture. No males, non-gravid females, nor juveniles were found.

During June 1991 we captured six gravid female *H. viridiflavus*, but still no males, non-gravid females, nor juveniles were observed. Gravid females were processed as before. Four of the six snakes were recaptures.

During June 1992, we captured two gravid females, while no other snakes were observed. Both females had been marked in 1990 and recaptured in 1991. This suggests that reproduction is annual at this site. There was a strong positive correlation between clutch size and female total length($r = 0.82$, Y-intercept = -18.41, slope = 0.198, $F = 22.80$, $P = 0.0005$). Because growth was slow fecundity also increased slowly as snakes aged (see Table 1).

All female *H. viridiflavus* marked during this study were observed near the stony box only during June (i.e., shortly before egg laying; see Luiselli and Rugiero 1990. Herpetozoa (Wien) 2:107–115), while absent during the rest of the year. On the other hand, juveniles were observed from late August to mid September (i.e., shortly after egg hatching), but not seen during other parts of the year.

Based on our observation we formulated preliminary conclusions: 1) The study site was regularly visited by female snakes for egg laying, possibly due to conditions favorable for incubation; 2) Nest site fidelity was high. Females used the site for egg laying in different years. We do not know if females stay in the area of the stone box during other times of the year. A telemetric study could resolve this question. If females use the area around the box only for nesting several questions remain unanswered. 1) How far do females travel from habitats used in other times of the year? 2) What conditions make the area around the stony box suitable as a nest site? 3) How do females navigate and recognize the nest site? We continue to study this phenomenon in order to answer these and other questions. Recently we discovered two other communal nest sites within a few kilometers of the study site, suggesting that communal nesting may be relatively common for *H. viridiflavus*.

TABLE 1. Gravid *Hierophis viridiflavus* captured during June 1990, 1991, and 1992, respectively. Individuals are distinguished by letters (A, B, C, etc.). TL = total length (in cm); CS = clutch size.

Snake	1990		1991		1992	
	TL	CS	TL	CS	TL	CS
A	117.2	4	118.0	4	118.7	4
B	121.3	6

Submitted by **MASSIMO CAPULA** and **LUCA LUISELLI**, Dipartimento di Biologia Animale e dell'Uomo, Università di Roma "La Sapienza," via A. Borelli 50, 00161 Roma, Italia.

LEPTOPHIS MODESTUS (NCN). **MORPHOLOGY**. On 19 July 1991, I collected a specimen of *Leptophis modestus* in Honduras, Departamento Comayagua, Cordillera de Montecillos, 1.6 km N, 0.2 km E Cerro San Juanillo, elevation 1960 m (14°29'44" N, 87°53'03" W). It was active in vegetation 4 m above ground in cloud forest dominated by the trees *Quercus skinneri, Matudea trinervia, Persea americana* var. *nubigena*, and *Podocarpus oleifolius*.

The snake was an adult male, SVL 1201 mm, tail 802 mm, 386 g. Nasal was divided, loreal absent (fused with prefrontal which borders 2nd and 3rd supralabials) preoculars 2; postoculars 2; temporals 1-2; supralabials 8-8 with 4th and 5th entering orbit; infralabials 11-10; ventrals 177; anal divided; dorsal scales in 15-15-11 rows with 1st row smooth and all others strongly keeled. Dorsum was uniform green; keels dirty yellow-green, most conspicuous at midbody; overlapped edges of dorsals blue, posterior tips black; lower, anterior dorsals yellow; midbody and posterior dorsals with black lower and trailing edges; skin between dorsal scales black. Venter bright yellow anteriorly grading to bluish and to pale green posteriorly. Rostral and supralabials yellow with green upper edges; a short, narrow postocular black bar on the upper edges of supralabials 7 L and 7-8 R; chin yellow cream grading to bright yellow on throat; iris golden with brown medial horizontal bar; tongue metallic blue.

Absence of a loreal plate and the presence of two preoculars instead of one adds to the range of morphologic variation reported for this species (Fig. 1). The specimen keys out to *Leptophis ahaetulla occidentalis* (using Peters and Orejas-Miranda. 1970. U.S. Natl. Mus. Bull. No. 297, 347 pp.). While the presence or absence of a loreal is a key character in diagnosing species, most of the species of *Leptophis* (= *Thalerophis*) exhibit variation (Oliver 1948. Bull. Amer. Mus. Nat. Hist. 92(4):160–280). This locality extends the known range 45 km to the east (Wilson et. al. 1986. Milwaukee Publ. Mus. Contr. Biol. and Geol. No. 66, 8 pp). Identification was verified by Gustavo A. Cruz and the specimen is deposited at Universidad Nacional Autonoma de Honduras (UNAH 2747).

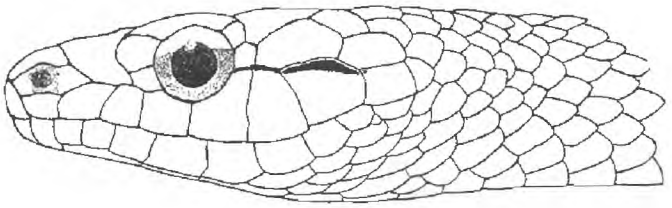

FIG. 1. Profile of *Leptophis modestus*, UNAH 2747.

Submitted by **PETER HOLM**, Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, Arizona 85721, USA.

LIASIS OLIVACEUS (Olive Python). **ALBINISM**. In March 1993 a female albino olive python (*Liasis olivaceus*) was collected near Woodcutters Mine, 80 km south of Darwin, Northern Territory, Australia. The animal is being kept alive at the Northern Territory University. The mining site is surrounded by small rocky hills dominated by eucalypt forest. At capture this animal was a subadult, ca. 1.5 m SVL (Shine 1992. Australian Snakes: A Natural History. Reed Books Pty Ltd., Balgowlah, 223 pp.). This python bears the pink eyes and tongue characteristic of an albino; however, the dorsal surface is cream-colored rather than white. The ventral surface is white. This is the first known report of albinism in this species.

Submitted by **GAVIN S. BEDFORD**, School of Biological Sciences, Northern Territory University, P.O. Box 40146 Casuarina, N.T., Australia, and **ROB COWARD**, Karama, N.T., Australia.

NERODIA SIPEDON SIPEDON (Northern Water Snake). **FEEDING**. On 24 June 1993 a young-of-the-year northern water snake was observed hunting smallmouth salamander (*Ambystoma texanum*) larvae in a small, shaded, temporary pond near the Charleston side-channel reservoir (NW1/4 Sec. 24, T11N, R9E), Coles Co., Illinois.

The pond (about 10 m long, 1 m wide, and 30 cm deep) was located at the bottom of a forested east-facing slope. A variety of aquatic macrophytes, insects, and *Bufo* larvae also inhabited the pond, but no fish were present.

I observed the water snake for about fifteen minutes. The snake waited at the water's surface supported by the vegetation. Its head

was raised above the water in an s-shape. When the smallmouth salamander larva broke the surface of the water to breath, the snake would strike and grab the salamander. The snake then proceeded to eat it. The foraging sequence was repeated about three times before the larva was captured.

San Diego, CA 92137

RHADINAEA LACHRYMANS (NCN). **PREY.** The diet of *Rhadinaea lachrymans* consists mainly of frogs, toads, and salamanders, in addition to terrestrial egg masses of frogs (*Eleutherodactylus*) and salamanders (Myers 1974. Bull. Amer. Mus. Nat. Hist. 153(1):81). Here, we report an observation of *R. lachrymans* feeding on *Bolitoglossa engelhardti*. On 16 April 1992, a juvenile female (MZFC 5967: SVL = 307 mm, TL = 421 mm) was collected by Adolfo Navarro in a cloud forest at El Chiquihuite (Volcan Tacana), Union Juarez, Chiapas, México, 2150 m elevation. Inspection of the stomach contents revealed a *Bolitoglossa engelhardti* (MZFC 5968: SVL = 29.6 mm). The body was intact and its tail had been broken into three pieces (1.6 + 7.6 + 19.0 = 28.2 mm).

Sazima et al. (1992. Herpetol. Rev. 23:120–121) suggested the small size, elongated head, and slender body of *Rhadinaea bilineata* make it well-suited for foraging on amphibians. The same generalizations apply to *Rhadinaea lachrymans*.

We thank Adolfo Navarro, Oscar Flores, and Mario Mancilla for comments on this manuscript and assistance in the field work. Financial assistance was provided by the Direccion General de Asuntos del Personal Academico (DGAPA) proyect IN201789.

Submitted by **FERNANDO MENDOZA QUIJANO** and **ALEJANDRA RENDON ROJAS,** Museo de Zoologia, Facultad de Ciencias, U.N.A.M. Apdo. Postal 70-399, México D.F. 04510, México.

SISTRURUS CATENATUS CATENATUS (Eastern Massasauga). **REPRODUCTION.** Throughout its range, the eastern massasauga (*Sistrurus catenatus*) demonstrates considerable variation in reproductive potential (Reinert 1981. Amer. Midl. Nat. 105:393–395). Mean litter size, for example, ranges from 5.3 in Texas to 11.1 in Wisconsin (Seigel 1986. Biol. Cons. 35:333–346). There are no published accounts of litter characteristics for the species in Ohio, where it is restricted to a few populations and currently recognized as a species of special interest, due largely to habitat loss.

Two pregnant *S. catenatus* were captured on 29 June 1993 at Area C of Wright-Patterson Air Force (WPAFB), Greene Co., Ohio. They were retained in individual enclosures heated to 27°C at the Dayton Museum of Natural History.

On 7 August 1993, the smaller female (500 mm SVL) gave birth to 9 neonates (6 male, 3 female) and 1 infertile ovum. Snout-vent length ranged from 154–190 mm (mean = 182.11, SD = 12.046). Body weight ranged from 7–8 g (mean = 7.556, SD = 0.527). On 21 August 1993 the larger female (565 mm SVL, 209 g) gave birth to 9 males. Snout-vent length ranged from 215–230 mm (mean = 223.667, SD = 5.788). Body weight ranged from 11–14 g (mean = 12.00, SD = 1.118). All neonates were sexed by probing. The offspring of the second female were significantly longer and heavier than those of the first female (ANOVA for SVL: df = 1, f = 87.015, p< 0.01; ANOVA for mass: df = 1, f = 116.364, p< 0.01 respectively). When the effects of body size were removed, there were no significant differences in weight between litters (ANCOVA for mass: df = 1, f = 0.099, p = 0.7571).

The mean litter size of these females is comparable with the mean reported for an Illinois population (mean = 9.5, SD = 3.209; Wright 1941. Amer. Midl. Nat. 25: 659–672). In terms of size at birth, these two litters were similar to the Pennsylvania population with mean for Ohio of 202.9 mm (SD = 23.26) and 206.2 mm (SD = 32.524) for Pennsylvania (Swanson 1933. Copeia 1933:37). Seigel and Fitch (1985. J. Anim. Ecol. 54:497–505) found litter size variation was higher within than between populations, and attributed this to female size differences. In the present case, the adult females differed in body size, but litter size did not. The variation in size at birth, however, could be attributed to difference in female body size, with larger females having larger neonates.

All animals used in this study were marked, photographed for dorsal pattern recognition, and released at the maternal capture site.

I thank T. Lucas and the rest of WPAFB Office of Environmental Management for logistic support and permission to capture rattlesnakes. I am grateful to the Dayton Museum of Natural History for providing lab space. This study was conducted under contract with The Nature Conservancy.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors must adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19:1–41; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985(3):802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen only when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to the Section Co-editors, Joseph T. Collins (USA & Canadian records only), Natural History Museum—Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA (E-mail: jcollins@kuhub.cc.ukans.edu), or Jerry D. Johnson (the rest of the world), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Painter, C. W., and C. M. Milensky. 1993. Geographic Distribution. *Crotalus tigris*. Herpetol. Rev. 24:155–156.

CAUDATA

AMPHIUMA MEANS (Two-toed Amphiuma). USA: FLORIDA: Taylor Co: Tide Swamp Unit, Big Bend Wildlife Management Area, SE 1/4 Sec. 1, Verified by David L. Auth. Florida Museum of Natural History (UF 91101). One adult caught during drift-fence study in fresh water marsh. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians in Florida. Part Three. The Amphibians. Second ed. Windward Publishing, Miami, Florida. 191 pp.).

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 663 Plantation Road, Perry, Florida 32347, USA.

AMPHIUMA PHOLETER (One-toed Amphiuma). USA: FLORIDA: Taylor Co: Spring Creek Unit, Big Bend Wildlife Management Area. 1992. Kristin N. Wood. Verified by David L. Auth. Florida Museum of Natural History (UF 91094). Adult caught in drift-fence array. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part Three. The Amphibians. Second ed. Windward Publishing, Miami, Florida. 191 pp.).

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 663 Plantation Road, Perry, Florida 32347, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). CANADA: NOVA SCOTIA: Cumberland Co: Emery Meadows, 45°38'30"N, 63°46'W. 16 May 1993. S. C. Friet and M. D. MacDonald. Verified by John Gilhen. Nova Scotia Museum of Natural History (NSM 10248). County record. One adult female found guarding nest of 25 eggs; located in sphagnum and grass along NE edge of small pool at head of Emery Brook, NW corner of Emery Meadows Bog; Ducks Unlimited Canada marsh adjacent to Trans-Canada Highway 114, 45°41'30"N; 63°43'W. 26 June 1993. S. C. Friet and M. D. MacDonald. Verified by J. Gilhen. NSM 10249. One female guarding a nest of 15 eggs; found at the base of a spruce snag in sphagnum at NE edge of marsh. These two records greatly expand the known range in Nova Scotia and may offer a possible range link with New Brunswick.

Submitted by **STEPHEN C. FRIET** and **MICHAEL D. MACDONALD**, Department of Biology, Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia B3H 4J1, Canada.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: VIRGINIA: Scott Co: Jefferson National Forest, beaver meadow along Glady Fork, ca. 10 km SE Norton, 2900 feet (884 m). All captures were made at a drift fence/pitfall array operated by the Division of Natural Heritage, Virginia Department of Conservation and Recreation: 11–23 June 1993 (Carnegie Museum of Natural History, CM 140195), 23 June–22 July 1993 (Virginia Museum of Natural History, VMNH 6537) and 22 July–18 August 1993 (VMNH 6538). All verified by Joseph C. Mitchell. New county record; first record from extreme SW Virginia (Tobey 1985, Virginia's Amphibians and Reptiles: A Distributional Survey. Publ. Virginia Herpetol. Soc., Purcellville, Virginia. 114 pp.) Extends range in Virginia ca. 200 km W of record from Buffalo Mountain, Floyd County (J. C. Mitchell and C. A. Pague, unpubl. data) and partially fills in the range gap between Virginia and Kentucky depicted in Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **STEVEN M. ROBLE** and **CHRISTOPHER S. HOBSON**, Division of Natural Heritage, Virginia Department of Conservation and Recreation, 1500 East Main Street, Suite 312, Richmond, Virginia 23219, USA.

NOTOPHTHALMUS VIRIDESCENS PIAROPICOLA (Peninsula Newt). USA: FLORIDA: Taylor Co: Spring Creek Unit, Big Bend Wildlife Management Area. 1992. Kristin N. Wood. Verified by David L. Auth. Florida Museum of Natural History (UF 91099). Specimen caught in drift-fence array. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part Three. The Amphibians. Second ed. Windward Publishing, Miami, Florida, 191 pp.).

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 663 Plantation Road, Perry, Florida 32347, USA.

ANURA

BUFO PUNCTATUS (Red-spotted Toad). USA: NEW MEXICO: Roosevelt Co: Melrose Bombing Range, 21.6 km S and 8.8 km E

of Tolar, Sheep Canyon. 7 August 1993. C. M. McCain and J. N. Stuart. University of New Mexico Museum of Southwestern Biology (MSB 56517–18, adults), USNM 335065 (lot of 3 tadpoles); 28 August 1993. D. T. Scott. MSB 56477 (lot of 3 juveniles). All verified by W. G. Degenhardt and S. W. Gotte. New county record; extends range SE in New Mexico from known localities in Quay and De Baca counties (W. G. Degenhardt, C. W. Painter, and A. H. Price, *in litt.*) to the western escarpment of the Llano Estacado (Southern High Plains). The paucity of records from on the Llano Estacado proper in eastern New Mexico and western Texas (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Press, College Station. 434 pp.) suggests a general lack of suitable habitat for *B. punctatus*, except at the margins of the plain.

Submitted by **JAMES N. STUART** and **DAMIEN T. SCOTT**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

HYLA CHRYSOSCELIS (Cope's Gray Treefrog). USA: FLORIDA: Taylor Co: Tide Swamp Unit, Big Bend Wildlife Management Area, NW 1/4 Sec. 28, T8S, R7E. 9 November 1993. Kristin N. Wood. Verified by David L. Auth. Florida Museum of Natural History (UF 91095). One adult caught in a hardwood swamp adjacent to a drift-fence array. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part Three. The Amphibians. Second ed. Windward Publishing, Miami, Florida, 191 pp.).

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 663 Plantation Road, Perry, Florida 32347, USA.

RANA CAPITO AESOPUS (Florida Gopher Frog). USA: FLORIDA: Taylor Co: Perry, jct. Osceola Street and Plantation Road, SE 1/4 Sec. 30, T4S, R8E. 30 May 1994. Harry J. Dutton. Verified by David L. Auth. Florida Museum of Natural History (UF 91093). Specimen caught in swimming pool. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part Three. The Amphibians. Second ed. Windward Publishing, Miami, Florida, 191 pp.).

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 663 Plantation Road, Perry, Florida 32347, USA.

RANA CATESBEIANA (Bullfrog). USA: ILLINOIS: DeKalb Co: Kishwaukee River, City of DeKalb, 41°55.8'N, 88°45.8'W. 10 June 1993. H. D. Walley. Verified by Tom Near. Northern Illinois University (HDW-NIU 1510–1). County record; fills gap between Lee and Cook counties (Smith 1961, The Amphibians and Reptiles of Illinois. Bull. Illinois Nat. Hist. Surv. 28:1–298); LaSalle Co: Paw Paw Creek, Paw Paw, 41°55.8'N, 88°45.8'W, 12 August 1994, H. D. Walley. HDW-NIU 1518. Verified by Tom Near. County record; fills gap between Knox, Fulton and McClean counties (Smith, *op. cit.*).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA.

RANA PALUSTRIS (Pickerel Frog). USA: ILLINOIS: Calhoun Co: Madison Creek, Tepen Hollow Road (NE 1/4 Sec. 17, T12S, R2W). 2 September 1994. J. K. Tucker and J. B. Camerer. Verified by C. Phillips. Illinois Natural History Survey (INHS 11353); Middle Fork of Fox Creek, along Bess Hollow Road, ca. 2.8 km NW jct. with Rt. 96 (NE 1/4 Sec. 1, T9S, R3W). 6 October 1994. M. Redmer. Verified by M. J. Blanford. Department of Zoology, Southern Illinois University at Carbondale (SIU-C H4738–4739). New county record. Jersey Co: Chautauqua (NE 1/4 Sec. 13, T6N, R12W). 3 May 1962. R. Brown. Verified by M. J. Blanford. Department of Biological Sciences, Southern Illinois University at Edwardsville (SIU-E 1598); Chautauqua Resort (Sec. 13, T6N, R12W). 17 April 1968. D. Thompson. Verified by M. J. Blanford. SIU-E 1591. Field tag erroneously places this locality in Madison County; Grafton, 1.8 km N and 1 km E of Rt. 100 and River Road (NE 1/4 Sec. 10, T6N, R12W). 17 April 1971. L. J. LaJeone. Verified by M. J. Blanford. SIU-E 1601–1602; Wooded stream parallel to Rosedale Road, behind Mississippi River State Waterfowl Management Area Headquarters (NW 1/4 Sec. 21, T21N, R1W). 6 October 1994. M. Redmer. Verified by M. J. Blanford. SIU-C H 4740. New county record; Madison Co: base of limestone bluff at edge of creek (Sec. 8, T6N, R10W). 4 April 1967. S. L. Smith. Verified by M. J. Blanford. SIU-E 1592; Alton, 0.4 km N of Mississippi River in swampy area (probably Sec. 5, T5N, R10W). 8 May 1963. G. Thompson. Verified by M. J. Blanford. SIU-E 1592. New county record; These three county records fill a gap in the Illinois distribution of *Rana palustris* between Pike and Greene counties on the north to St. Clair County on the south (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298; Redmer and Ballard 1995, Herpetol. Rev. 26(1):49–53). With the exception of Jackson County, the documented range of this species now includes all Mississippi River border counties from Adams County on the north to Alexander County on the south. All live specimens collected in 1994 had golden yellow flash coloration on their thighs (Redmer and Mierzwa 1994, Bull. Chicago Herpetol. Soc. 29:21–30).

Submitted by **MICHAEL REDMER**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901, USA, **JAMES B. CAMERER** and **JOHN K. TUCKER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 4134 Alby Street, Alton, Illinois 62002, USA, and **JEFFERY CAPPS**, Department of Biological Sciences, Southern Illinois University at Edwardsville, Edwardsville, Illinois 62026, USA.

RANA PIPIENS (Northern Leopard Frog). USA: ARIZONA: Mohave Co: Truxton Spring at Truxton Wash. NE 1/4 SE 1/4 Sec. 26, T24N, R13W. 3 August 1994. J. Eric Wallace. Adult male and female. Verified by James E. Platz. Arizona State University Lower Vertebrate Collection (ASU 30214–30215). Only Northern Leopard Frogs found to date in Mohave County. These frogs represent an isolated population 160 km WNW of the nearest known extant population in Arizona.

Submitted by **J. ERIC WALLACE**, Arizona Game and Fish Department, Nongame Branch, 2221 West Greenway Road, Phoenix, Arizona 85023, USA.

SPEA MULTIPLICATA (New Mexico Spadefoot). USA: COLORADO: El Paso Co: erosion control pond adjacent to West Fork of Red Creek, U.S. Army Fort Carson Military Reservation, 13 km NE Penrose, 38°32'55"N, 104°55'58"W. 7 June 1991. Richard L. Bunn. Verified by Hobart M. Smith. UCM photograph 92. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.). Northernmost known locality in the Arkansas River drainage.

Submitted by **RICHARD L. BUNN**, Wildlife Branch, DECAM, AFZC-ECM-NR, Building 302, Fort Carson, Colorado 80913-5000, USA.

CROCODYLIA

PALEOSUCHUS TRIGONATUS (Schneider's Smooth-fronted Caiman). GUYANA: Region I (NORTH-WEST DISTRICT): Almond Beach near Waini Point (8°23.969'N, 59°45.286'W; cf. Waini Point at 8°23.738'N, 59°48.786'W). 7 July 1993. P. C. H. Pritchard. Verified by David Auth. 109 cm (total length) adult male (tip of tail missing) emerged from sea and rested on beach. Photographed and videotaped. Kodachrome slide deposited in Florida Museum of Natural History (PCHP 002 October 1994). Animal was underweight but seemingly healthy; it was released in a freshwater pond behind the beach. First marine record for species; closest records are from Lower Demerara and Lower Essequibo rivers, Guyana (Medem 1983, Crocodylia de Sur America, Vol. 2:95); closest Venezuela record is from Angostura, Lower Orinoco (Lichtenstein and von Martens 1856, Nomenclatur Reptilium et Amphibium Musei Berolinensis, iv: 48. Berlin).

Submitted by **PETER C. H. PRITCHARD**, Florida Audubon Society, 400 Hwy 436 #200, Casselberry, Florida 32707, USA.

TESTUDINES

APALONE SPINFERA (Spiny Softshell). USA: ILLINOIS: LaSalle Co: 1.75 miles (2.8 km) W Utica, Pecumsaugan Creek, SW 1/4 Sec. 7 T33N, R2E. 10 May 1992, H. D. Walley. Verified by Tom Near. Northern Illinois University (HDW-NIU-1493). County record; fills gap between DeKalb, Kendall and Putnam counties (Smith 1961, The Amphibians and Reptiles of Illinois. Bull. Illinois Nat. Hist. Surv. 28:1–298).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois, DeKalb, Illinois 60115.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: COLORADO: Arapahoe Co: South Platte Park, NW 1/4 Sec. 32, T5S, R68W. 17 June 1993. Raymond H. Sperger. Verified by Lauren Livo. UCM color slide 87 of a female that had just laid a total of ca. 50 eggs. First county record and maximum number of eggs recorded in Colorado (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife. Denver. 131 pp.).

Submitted by **RAYMOND H. SPERGER**, Theo. H. Carson Nature Center, 7301 South Platte River Parkway, Littleton, Colorado 80120-2968, USA; **ROSANNE HUMPHREY**, **DAVID CHISZAR**, and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

CHRYSEMYS PICTA BELLII (Western Painted Turtle). USA: COLORADO: Arapahoe Co: South Platte Park on Mineral Avenue between Lake 5 and Cooley Lake, S side of west-bound lanes, SE 1/4 Sec. 30, T5S, R68W. 2 August 1992. Raymond H. Sperger. Verified by Lauren Livo. UCM 57019. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.).

Submitted by **RAYMOND H. SPERGER**, Theo L. Carson Nature Center, 7301 South Platte River Parkway, Littleton, Colorado 80120-2968, USA; **ROSANNE HUMPHREY**, **DAVID CHISZAR**, and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

DERMATEMYS MAWII (Central American River Turtle). MEXICO: QUINTANA ROO: La Union, Hondo River, 6 km NE La Union town (17°53'47"N, 88°52'34"W). 24 June 1994. Collected by M. Suárez and H. Bahena Basave. Verified by O. Flores-Villela. Museo de Zoologia del Centro de Investigaciones de Zuintana Roo (MZCIQRO 339). New record to Quintana Roo, Yucatan Peninsula, that verifies suspected distribution in Quintana Roo state (Iverson 1992, A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana. 363 pp.)

Submitted by **HUMBERTO BAHENA-BASAVE**, Dirección de Recursos Naturales, Centro de Investigaciones de Quintana Roo, Chetumal, Quintana Roo 77000, México.

GRAPTEMYS PSEUDOGEOGRAPHICA OUACHITENSIS (Ouachita Map Turtle). USA: MISSISSIPPI: Sunflower Co: Quiver River, 0.8 river km NE of Big Sunflower and Quiver Rivers confluence, Sec. 25, T19N, R4W. 1 September 1994. K. J. Killgore and J. Morrow. Verified by Neil H. Douglas. Northeast Louisiana Univ. Mus. of Zool. (NLU 70490). This voucher represents a new county record and confirms presumed distribution in this area (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **STEVEN G. GEORGE**, **JACK KILLGORE**, and **SHERRY L. HARREL**, U.S. Army Engineer Waterways Experiment Station, ER-A, 3909 Halls Ferry Road, Vicksburg, Mississippi 39180-6199, USA.

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). USA: ILLINOIS: Pulaski Co: 2 mi E Karnak. 12 August 1976. L. M. Page and M. A. Morris. Verified by Christopher A. Phillips. Illinois Natural History Survey (INHS 10304). First record for county. Pope Co: 1 mi W New Liberty on Unionville Road, in flooded hardwood forest in a foot of water at the base of a young tree adjacent to a remnant bald cypress swamp. 17 April 1994. K. Jacobson. Southern Illinois University at Carbondale Herpetology Collection (SIUC R-2689, adult male, carapace length 10.2 cm); identifiable plastron and other hard parts on a road adjacent to the same swamp. 2 June 1994. R. A. Brandon and M. Redmer. SIUC R-2672. First voucher specimens from a specific locality in county, although there have been other indications this turtle occurs in there. Cagle (1946, Am. Midl. Nat. 36:690–691) mentioned finding this species in "... a drainage ditch south of Dixon Springs, Illinois," and Smith (1961, Illinois Nat. Hist. Surv. Bull. 28:1–298) placed this locality in Pope County. There is another Pope County specimen (Carnegie Museum of Natural History 108574) collected by Edward Moll in 1971, but it lacks specific locality information.

Submitted by **RONALD A. BRANDON**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901, USA, and **KRISTINE JACOBSON**, 276 Cedar Creek Road, Makanda, Illinois 62958, USA.

STAUROTYPUS TRIPORCATUS (Mexican Giant Musk Turtle). MEXICO: QUINTANA ROO: La Union, Hondo River, 6 km NE La Union town (17°53'47"N, 88°52'34"W). 28 January 1993. Collected by H. Bahena Basave. Verified by O. Flores-Villela. Museo de Zoologia del Centro de Investigaciones de Zuintana Roo (MZCIQRO 340). New record for Quintana Roo, Yucatan Peninsula, that verifies and confirm a doubtful record in central part of Quintana Roo state (Iverson 1992, A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana. 363 pp.)

Submitted by **HUMBERTO BAHENA-BASAVE**, Dirección de Recursos Naturales, Centro de Investigaciones de Quintana Roo, Chetumal, Quintana Roo 77000, México.

TERRAPENE CAROLINA CAROLINA (Eastern Box Turtle). USA: ILLINOIS: Scott Co: NE 1/4 Sec. 20, T14N, R12W, Winchester Road, 0.2 km N Winchester. 21 August 1994. J. K. Tucker. Verified by Chris Phillips, Illinois Natural History Survey (INHS 11322). New county record, extends documented range 28 km NE of nearest previous documented record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298) and east of undocumented record for Morgan County (Applegate 1975, Trans. Illinois State Acad. Sci. 68:17). However, location of the latter record is uncertain as township and range cited in paper is actually located in Montgomery County from which Smith (*op. cit.*) reported documented records of the species.

Submitted by **JOHN K. TUCKER** and **JAMES B. CAMERER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 4134 Alby Street, Alton, Illinois 62002, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). USA: ILLINOIS: Calhoun Co: NE 1/4 Sec. 27, T8S, R2W, 3.7 km N Kampsville on Illinois Rt. 100. 24 May 1994. J. K. Tucker. Verified by C. Phillips, Illinois Natural History Survey (INHS 11323). New county record.

Submitted by **JOHN K. TUCKER** and **JAMES B. CAMERER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 4134 Alby Street, Alton, Illinois 62002, USA.

AMPHISBAENIA

RHINEURA FLORIDANA (Florida Worm Lizard). USA: FLORIDA: Taylor Co: Athena, Josh Ezel Grade. August 1993. Cindy Hunt. Verified by David L. Auth, Florida Museum of Natural History (UF 91089). Collected while excavating in a scrub oak habitat. New county record (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part Two. Lizards, Turtles and Crocodilians. Windward Publishing, Miami, Florida, 191 pp.) and partially fills the range hiatus as shown in Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). Extends the range of this species 40 km NW of the westernmost locality in the state (Meylan 1984, Herpetol. Rev. 15:23–24). There is a record from Liberty County, which is farther west than Taylor County, but it is believed to be based on unreliable data (David L. Auth, pers. comm.).

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 663 Plantation Road, Perry, Florida 32347, USA.

LACERTILIA

ANOLIS DISTICHUS (Bark Anole). USA: FLORIDA: Monroe Co: Key Vaca, Marathon, small woodland near Mile Marker 50 on U.S. Rt. 1. 29 July 1994. Gregory J. Watkins-Colwell. Verified by E. E. Williams. Animal photographed in the wild. KU 221730. Several adults and juveniles found on utility poles and tree trunks near open areas of the woodland. County and locality record for this introduced species (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part Two: Lizards, Turtles and Crocodilians. Windward Publ., Miami, Florida, 191 pp.; Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **GREGORY J. WATKINS-COLWELL**, Department of Biology, Sinclair Community College, 444 West Third Street, Dayton, Ohio 45402, USA, and **KELLIE A. WATKINS-COLWELL**, 2323 North Knoll Drive, Beavercreek, Ohio 45131, USA.

ANOLIS JACARE (NCN). VENEZUELA: ESTADO TACHIRA: Betania, 2150 m. 2 February 1979. Jaime Péfaur. Colección de Vertebrados de la Universidad de Los Andes (CVULA 896). First State record; Estado Merida: Monte Zerpa, 2200 m., 26 October 1990. Amelia Díaz de Pascual. CVULA 1698. Northernmost record for the species. Both verified by Juan Elías García Pérez. These specimens were identified as *Phenacosaurus niceforoi* in CVULA collection and most probably correspond to the localities, without vouchers, of "región de Betania, hacia el Páramo de Tamá, Estado Táchira" and "cercanías de la Ciudad de Mérida" reported for this species by Péfaur and de Pascual (1982, Actas VIII Congreso Latinoamericano de Zoología, Oct. 1980, Mérida, Venezuela:241). Táchira records extends known range ca. 190 km SW of the type locality (Boulenger 1903, Ann. Mag. Nat. Hist. [7]11:482; Williams et al. 1970, Breviora 353:1–15). Based on current evidence, the presence of *Phenacosaurus niceforoi* in the Venezuelan Andes is rejected, and the statement that this taxon is shared by the Cordillera de Mérida and the Colombian Cordillera Oriental (Péfaur and de Pascual 1984:249, 251) remains to be supported.

Submitted by **ENRIQUE LA MARCA**, Universidad de Los Andes, Facultad de Ciencias Forestales, Instituto de Geografía y Conservación de Recursos Naturales, Apartado Postal 116, Mérida 5101-A, Venezuela.

ANOLIS LAEVIVENTRIS (White Anole). MÉXICO: HIDALGO: Municipality of San Bartolo Tutotepec (20°25'N, 98°12'W) near Condege. 22 May 1970. J. Gimate. Verified by Ticul Alvarez Solórzano. Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional (ENCB 6377). First state record; extends known range at least ca. 165 km NW from former records in central Veracruz (Xalapa, Actopan, Mirador, Orizaba, Xicaltepec, and Xico; Smith and Taylor 1950, Bull. U.S. Natl. Mus. 199:1–253).

Submitted by **ADRIAN-NIETO MONTES DE OCA**, Natural History Museum, University of Kansas, Lawrence, Kansas 66045-2454, USA, and **FERNANDO MENDOZA-QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, México, Distrito Federal 04510, México.

ANOLIS LEMURINUS BOURGEAEI (Bourgeae's Ghost Anole). MÉXICO: HIDALGO: Municipality of San Bartolo Tutotepec, 3 km N San Bartolo Tutotepec (20°25'N, 98°12'W), 1190 m elev. 3 April 1979. A. Flores. Verified by Ticul Alvarez Solórzano. Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional (ENCB 10881). First state record; extends known range at least ca. 190 km NW from former records in central Veracruz (Huatusco and Orizaba; Smith and Taylor 1950, Bull. U.S. Natl. Mus. 199:1–253).

Submitted by **ADRIAN-NIETO MONTES DE OCA**, Natural History Museum, University of Kansas, Lawrence, Kansas 66045-2454, USA, and **FERNANDO MENDOZA-QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, México, Distrito Federal 04510, México.

ANOLIS SERICEUS (Silky Anole). MÉXICO: HIDALGO: Municipality of Huejutla de Reyes, 1 km S Tehuetlán (21°02'N, 98°31'W), 390 m elev. 14 May 1980. M. Rodríguez. Verified by Ticul Alvarez Solórzano. Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional (ENCB 11005). First state record. Lee (1980, Copeia 1980:310–320) provided locality records of the species for the states of Tamaulipas, San Luis Potosí, and Veracruz; Lee (1983, Cat. Am. Amphib. Rept. 340.1–340.2) included eastern Hidalgo and Puebla in his distribution map for the species, but did not provide locality records for these states. This record partly fills the hiatus between Xilitla, San Luis Potosí, ca. 60 km to the northwest, and records from Veracruz to the east and southeast (Lee 1980, *op. cit.*); Municipality of Actopan, 5 km E Actopan (20°16'N, 98°56'W). 8 March 1972. L. Ruiz. Verified by Ticul Alvarez Solórzano. ENCB 7301–04. Extends distribution at least ca. 260 km NW from former records in central Veracruz (vicinity of Córdoba, Lee 1980, *op. cit.*), and represents the inlandmost record for the species in the northern portion of its range.

Submitted by **ADRIAN-NIETO MONTES DE OCA**, Natural History Museum, University of Kansas, Lawrence, Kansas 66045-2454, USA, and **FERNANDO MENDOZA-QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70-399, México, Distrito Federal 04510, México.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). USA: FLORIDA: Taylor Co: Tide Swamp Unit, Big Bend Wildlife Management Area, NW 1/4 Sec. 33, T8S, R7E. 6 October 1993. Kristin N. Wood. Verified by David L. Auth. Florida Museum of Natural History (UF 91098). Specimen caught in drift-fence array. New county record (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part Two. Lizards, Turtles & Crocodilians. Second ed. Windward Publishing, Miami, Florida, 191 pp.).

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 663 Plantation Road, Perry, Florida 32347, USA.

COLEONYX BREVIS (Texas Banded Gecko). USA: NEW MEXICO: Lincoln Co: White Sands Missile range, Oscura Mountains, 9 km NE jct. Range Road 7 and Range Road 12; 4.6 km N Range Road 12 to Schist Site; ca. 40 air km E and 35 air km S San Antonio (33°32'10.5"N, 106°20'03.2"W). 30 May 1994. L. K. Kamees and D. W. Burkett. Verified by C. W. Painter. University New Mexico Museum Southwestern Biology (MSB 57268). County record (Degenhardt et al. The Amphibians and Reptiles of New Mexico. In press).

Submitted by **LARRY K. KAMEES** and **DOUGLAS W. BURKETT**, Cortez III Service Corporation, P.O. Box L, White Sands Missile Range, New Mexico 88002-9998, USA.

EUMECES FASCIATUS (Five-lined Skink). USA: FLORIDA: Taylor Co: Spring Creek Unit, Big Bend Wildlife Management Area. 1992. Kristin N. Wood. Verified by David L. Auth. Florida Museum of Natural History (UF 91096). Specimen caught in drift-fence array. New county record (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part Two. Lizards, Turtles & Crocodilians. Second Ed. Windward Publishing, Miami, Florida, 191 pp.).

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 663 Plantation Road, Perry, Florida 32347, USA.

EUMECES FASCIATUS (Five-lined Skink). USA: ILLINOIS: Jersey Co: S 1/2 Sec. 12, T6N, R13W, under tin, at Brussels Ferry, 3.8 km WNW Grafton, near Ill. Rt. 100. 18 May 1994. J. K. Tucker and J. B. Hatcher. Verified by C. Phillips. Illinois Natural History Survey (INHS 11412). New county record.

Submitted by **JOHN K. TUCKER** and **JAMES B. HATCHER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 3134 Alby Street, Alton, Illinois 62002, USA.

HEMIDACTYLUS MABOUIA (Tropical House Gecko). USA: FLORIDA: Monroe Co: Key Vaca, Marathon, under debris in a small woodland near mile marker 50 on U. S. Rt. 1. 25 July 1994. Gregory J. Watkins-Colwell. Verified by J. T. Collins. Juvenile caught under plywood in wooded area. KU 221732. This is a new island record, but not a county record, for this species (Meshaka et al. 1994, Herpetol. Rev. 25:80–81).

Submitted by **GREGORY J. WATKINS-COLWELL** and **KELLIE A. WATKINS-COLWELL**, Biology Department, Sinclair Community College, Dayton, Ohio 45402, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: FLORIDA: Escambia Co: Santa Rosa Island, Sabine Yacht Club, T3N, R29W. 6 August 1994. John B. Jensen and Jodie B. Jensen. Florida Museum of Natural History (UF 91969); Okaloosa Co: Ft. Walton Beach, apartment complex on South Avenue, 0.5 km west of Eglin Parkway, Sec. 1, T2S, R24W. 23 October 1994. LeAnn West. UF 94152–53. All verified by Paul Moler. New county records for this introduced species (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). Populations in both counties assumed to be well established based on individuals of various size classes observed.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

SCELOPORUS GRACIOSUS GRACIOSUS (Northern Sagebrush Lizard). USA: COLORADO: Grand Co: 1.3 km W and 1.3 km S Radium, SE 1/4 SW 1/4 Sec. 28, T1S, R82W. 16 September 1994. G. Horstman. Verified by L. J. Livo. UCM Color Slide 89. New county record; extends range ca. 14 km ENE of nearest records at McCoy, Eagle County (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Div. Wildl. Publ., Denver. 131 pp.).

Submitted by **GREG HORSTMAN**, Colorado Division of Wildlife, 711 Independent, Grand Junction, Colorado 81505, USA.

SCELOPORUS UNDULATUS (Fence Lizard). USA: ILLINOIS: Madison Co: NE 1/4 Sec. 10, T5N, R10W, on rocks near bluff, 0.6 km W Alton, near Ill. Rt. 100. 3 October 1994. J. K. Tucker. Verified by C. Phillips. Illinois Natural History Survey (INHS 11408). New county record.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 3134 Alby Street, Alton, Illinois 62002, USA.

SERPENTES

CLONOPHIS KIRTLANDII (Kirtland's Snake). USA: ILLINOIS: Shelby Co: NW 1/4 Sec. 1, T10N, R6E, under cardboard in relictual prairie between ICG railroad and U.S. Rt. 45, 1.2 mi N Sigel. 12 May 1994. J. K. Tucker. Verified by C. Phillips. Illinois

Natural History Survey (INHS 11351). Collected under Illinois Dept. Cons. Permit 94-3S. New county record; fills gap in range between Effingham and Coles counties (Brown et al. 1975, Herpetol. Rev. 6:78–79; Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **JOHN K. TUCKER** and **JAMES B. CAMERER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 4134 Alby Street, Alton, Illinois 62002, USA.

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer). USA: COLORADO: Arapahoe Co: South Platte Park, SE 1/4 Sec. 30, T5S, R68W. June 1991. Raymond H. Sperger. Verified by Lauren Livo. UCM color slide 88. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.).

Submitted by **RAYMOND H. SPERGER**, Theo L. Carson Nature Center, 7301 South Platte River Parkway, Littleton, Colorado 80120-2968, USA; **ROSANNE HUMPHREY**, **DAVID CHISZAR**, and **HOBART M. SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA.

COLUBER CONSTRICTOR FOXII (Blue Racer). USA: ILLINOIS: Greene Co: SE 1/4 Sec. 15, T10N, R10W, DOR Ill Rt. 108, 1.1 km W junction U.S. Rt. 67. 7 October 1994. J. K. Tucker. Verified by C. Phillips. Illinois Natural History Survey (INHS 11421). New county record.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 3134 Alby Street, Alton, Illinois 62002, USA, and **GARY L. PAUKSTIS**, 2489 Quail Court, Aurora, Illinois 60504, USA.

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). USA: ILLINOIS: Jersey Co: NE 1/4 Sec. 14, T6N, R12W, DOR Ill. Rt. 100, 0.3 km E Rice Hollow Road; NE 1/4 Sec. 21, T6N, R11W, DOR Ill. Rt. 100, 0.3 km E Elsah Road. 1 October 1994. J. K. Tucker. Both verified by C. Phillips. Illinois Natural History Survey (INHS 11444 and 11445, respectively). Previously reported by Smith (1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298) from Jersey County based on Principia College specimen (number 490) collected in 1949 which I reexamined to confirm identity. First listed specimen reported herein extends range of subspecies, which is listed as endangered in Illinois, 3.1 km WNW of Principia record.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 3134 Alby Street, Alton, Illinois 62002, USA.

HETERODON NASICUS (Western Hognose Snake). USA: ILLINOIS: Jo Daviess Co: Savanna Army Depot, SW1/4 Sec. 24, T26N, R1E, at the junction of River Road and Burning Grounds Road. 12 July 1994. M. McCallum and E. Moll. Illinois Natural History Survey (INHS color slide 1994-1). Verified by C. Phillips. New county record (male, length = 470 mm).

Submitted by **MALCOLM L. McCALLUM**, 103 Rex Drive, Collinsville, Illinois 62234, USA.

LAMPROPELTIS TRIANGULUM (Milk Snake). USA: ARIZONA: Cochise Co: 31°35'40"N 109°14'19"W. 23 June 1994. Andrew T. Holycross (Arizona Game and Fish scientific collecting permit HLYCR000038). Arizona State University Animal Care Facility (living specimen). Specimen captured in a drift fence/funnel trap array in a tobosa grassland. First county record and first verifiable record in Arizona south of the Mogollon Rim (Williams 1988. Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*, 2nd ed. Milwaukee Publ. Mus. 176 pp.). Extends range ca. 320 km south from the nearest known specimen to the north (Charles Lowe, pers. comm.) and ca. 225 km west from the nearest New Mexico locality (Degenhardt et al., in press. The Amphibians and Reptiles of New Mexico. Univ. of New Mexico Press, Albuquerque). The specimen is a male, 70.4 g body weight, 522 mm SVL, 613 mm total length. Confirms unpublished record for same location (UAZ 50283 photographic voucher). James P. Tracey and Dale T. Tracey. 15 July 1988. Verified by Charles Lowe. The Tracey specimen is also a male, 7.8 g body weight, 273 mm SVL, 314 mm total length. Measurements made on 9 September 1988.

Our specimen not only confirms the Tracey record but may lend credence to Yarrow's (1875. Rep. Geog. Geol. Expl. Surv. W 100th Mer., Engineer. Dept. U.S. Army 5:509-584) records from "Camp Apache, Ariz" as discussed by Williams (*op. cit.*). Although Williams (*op. cit.*, p. 92) did not verify these records and suggested that they may be *L. pyromelana*, he later (*op. cit.*, p. 93) states that he has "no reason to doubt" their authenticity. Apache (Cochise Co., Arizona) is apparently the "Camp Apache" of Yarrow (*op. cit.*) and lies ca. 16 km NE of our collection locality.

Another specimen was found subsequent to the previous records in the Animas Valley of New Mexico, ca. 30 km SE of the Holycross specimen. USA: NEW MEXICO: Hidalgo County: 2.4 km N of Cloverdale. 13 September 1994. Jeff Gee and Barney Tomberlin. Verified by Charles Painter. Museum of Southwestern Biology MSB 58186 (shed skin). Found in grassland beneath a board. First county record, first record for the Animas Valley, and fills a gap in the known distribution between the Arizona specimens and the nearest records in New Mexico (see above). The Peloncillo Mountains of Arizona and New Mexico separate the San Bernardino Valley (Arizona specimens cited above) and the Animas Valley (this specimen).

Submitted by **ANDREW T. HOLYCROSS**, Department of Zoology, Arizona State University, Tempe, Arizona 85827-1501, USA, and **CECIL SCHWALBE**, National Biological Survey, Cooperative Park Studies Unit, University of Arizona, Tucson, Arizona 85721, USA.

MICRURUS BROWNI (Brown's Coral Snake). MÉXICO: QUINTANA ROO: La Union, under litter, 0.15 km N La Union town (17°53'47"N, 88°52'34"W). 17 December 1992. Museo de Zoologia del Centro de Investigaciones de Quintana Roo (MZCIQRO 206); 8 km N La Union Town. 6 January 1993. MZCIZRO 209; La Union town. 3 February 1993. MZCIQRO 229; near Hondo River, 4 km NE La Union town. 20 February 1993. MZCIQRO 245; La Union town. 29 March 1993. MZCIQRO 253. All collected by Humberto Bahena Basave and verified by O. Flores-Villela. New record for Quintana Roo state and the Yucatan Peninsula (Lee 1980, Univ. Kansas Nat. Hist. Mus. Misc. Publ. 67:1–75).

Submitted by **HUMBERTO BAHENA-BASAVE**, Dirección de Recursos Naturales, Centro de Investigaciones de Quintana Roo, Chetumal, Quintana Roo 77000, México.

OPISTHOTROPIS KUATUNENSIS (Striped Stream Snake). HONG KONG TERRITORY: LANTAU ISLAND (Tai Yue Shan): Tei Tong Tsai, ca 300 m elev. Michael Lau. 19 May 1993. Verified by Stephen Karsen. Museum of Comparative Zoology (MCZ A 11991). First island voucher. Known distribution peculiarly dis-

continuous: known from southeastern (Fujian, Jiangxi, and Zhejiang) and south-central (Guangxi) China, but not Hunan or Guangdong in between (Zhao and Adler 1993, Herpetology of China. SSAR Contrib. Herpetol. 10:248). Also well known from the Hong Kong New Territories adjacent to Guangdong, but not Hong Kong Island (Karsen, Lau, and Bogadek 1986, Hong Kong Amphibians and Reptiles. Urban Council, Hong Kong: 100). Karsen et al. (idem.) mention Lantau Island, but Karsen reports (pers. comm.) that was a sight record.

Submitted by **JAMES LAZELL**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835, USA.

PITUOPHIS CATENIFER DESERTICOLA (Great Basin Gopher Snake). USA: COLORADO: Grand Co: 0.7 km W and 1.0 km S Radium, NW 1/4 SW1/4 Sec. 27, T1S, R82W. 16 September 1994. G. Horstman. Verified by L. J. Livo. UCM Color Slide 90. New county record; extends range ca. 41 km NE of nearest record near Eagle, Eagle County, in the Colorado River drainage and is the easternmost record of this subspecies in the state (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.).

Submitted by **GREG HORSTMAN**, Colorado Division of Wildlife, 711 Independent, Grand Junction, Colorado 81505, USA.

RHINOCHEILUS LECONTEI TESSELLATUS (Texas Longnose Snake). USA: OKLAHOMA: Texas Co: 0.45 km W Guymon. 15 October 1973. Collector unknown. Verified by Richard L. Holland. UCM 57039. First county record (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press, Norman, 370 pp.).

Submitted by **KURT SCHAEFER**, Department of Biology, Panhandle State University, Goodwell, Oklahoma 73939, USA; **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA; and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

SISTRURUS CATENATUS TERGEMINUS X EDWARDSII (Massasauga). USA: COLORADO: El Paso Co: school yard at Edison. September-October 1987 or 1988. Stephen T. Pegler. Verified by Richard L. Holland. UCM 57099. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.). The first author's experience indicates that until 1989 the species was moderately common in El Paso County, but thereafter became rare and now approaches extirpation in that general area. As an isolated population (Conant and Collins 1991, A Field guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin, Boston, Massachusetts. 450 pp.) it merits the protection already afforded by the Colorado Division of Wildlife, and stronger measures should be considered.

Submitted by **STEPHEN T. PEGLER**, Denver Seminary, 3401 South University Boulevard, No. 202, Englewood, Colorado 80110, USA; **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado, 80309-0345, USA; and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado, 80309-0334, USA.

TANTILLA CUCULLATA (Blackhood Snake). USA: TEXAS: Terrell Co: ca. 8 mi E Sanderson on U.S. Rt. 90 (AOR). 8 June 1991. Observed and photographed by John C. Fraser. KU Color Slide 11135. County record; fills hiatus between Pecos and Val Verde (as mapped by Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 434 pp); Val Verde Co: 3 mi S Loma Alta on U.S. Rt. 277 (AOR). 4 June 1991. Observed and photographed by John C. Fraser. KU Color Slide 11134. Both verified by John E. Simmons. Although not a county record, both this and the Terrell County specimen exhibit narrowly broken neck rings (characteristic of *Tantilla cucullata*), and the Val Verde County example, from an area on the E edge of the range of *T. diabola*, makes untenable the continued recognition of the Devil's River Blackhead Snake as a distinct taxon.

Submitted by **KELLY J. IRWIN**, 2218 West 2nd Street, Topeka, Kansas 66606, USA; and **JOSEPH T. COLLINS**, Natural History Museum, University of Kansas, Lawrence, Kansas 66045-2454, USA.

THAMNOPHIS PROXIMUS PROXIMUS (Western Ribbon Snake). USA: ILLINOIS: Greene Co: NE 1/4 Sec. 21, T9N, R13W, DOR on Co. Rd. 325E, 0.2 km N junction with Co. Rd. 630N. 17 October 1994. J. K. Tucker. Illinois Natural History Survey (INHS 11426). Calhoun Co: SE 1/4 Sec. 29, T8S, R3W, DOR on Ill. Rt. 96 at jct. with Co. Rd. 3180N (Infidel Hollow Road). 19 October 1994. J. K. Tucker. INHS 11428. Verified by C. Phillips. Illinois Natural History Survey (INHS). New county records.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 3134 Alby Street, Alton, Illinois 62002, USA.

THAMNOPHIS SIRTALIS PARIETALIS (Red-sided Garter Snake). USA: OKLAHOMA: Beaver Co: Slapout. 17 March 1974. Collector unknown. Verified by Richard L. Holland. UCM 57037. First county record (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press, Norman, 370 pp.) and a westward range extension of ca. 48 km from Ft. Supply, (Woodward County) for the subspecies in Oklahoma.

Submitted by **KURT SCHAEFER**, Department of Biology, Panhandle State University, Goodwell, Oklahoma 73939, USA; **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA; and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). USA: ILLINOIS: Scott Co: NE 1/4 Sec. 20, T14N, R12W, Winchester Road, 0.1 km N Winchester. 21 August 1994. J. K. Tucker. Verified by Chris Phillips, Illinois Natural History Survey (INHS 11350). New county record.

Submitted by **JOHN K. TUCKER** and **JAMES B. CAMERER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 4134 Alby Street, Alton, Illinois 62002, USA.

TRETANORHINUS NIGROLUTEUS (Orangebelly Swamp Snake). MÉXICO: QUINTANA ROO: La Union, in Hondo River, 3 km NE La Union town (17°53'47"N, 88°52'34"W). 27 January 1993. H. Bahena Basave. Museo de Zoologia del Centro de Investigaciones de Quintana Roo (MZCIQRO 223); in Hondo River, La Union town, 31 March 1993. H. Bahena Basave. Both verified by O. Flores-Villela. MZCIQRO 258. New record to Quintana Roo, Yucatan Peninsula.

Submitted by **HUMBERTO BAHENA-BASAVE**, Dirección de Recursos Naturales, Centro de Investigaciones de Quintana Roo, Chetumal, Quintana Roo 77000, México.

New Island Records from Panay, Philippines

Even though the island of Panay ranks seventh in size in the Philippine Archipelago, until recently few faunal surveys had been done there (Gonzales and Kennedy 1990). From 1983 through 1989 the National Museum of the Philippines (PNM) sponsored several expeditions to Panay, the last being co-sponsored by the Cincinnati Museum of Natural History (CMNH). Fourteen new island records of amphibians and reptiles are reported below with specimens being deposited at either CMNH or PNM. Common names were taken from Alcala (1986) when available. Records were checked in Alcala (1986) and against the catalogs of the following collections: California Academy of Sciences, Carnegie Museum of Natural History, Field Museum of Natural History, National Museum of the Philippines, The Rabor Collection (University of the Philippines at Los Banos), U.S. National Museum of Natural History, and an unpublished list compiled by Ronald I. Crombie. Identifications were verified by Ronald I. Crombie.

ANURA

Rana everetti (Everett's Frog). Antique Province: Valderrama Municipality: Barrio San Agustin, Mt. Baloy, 210 m elev. 4 October 1989. J. W. Ferner. CMNH 3153. Island record.

Rana leytensis (Leyte Frog). Antique Province: Valderrama Municipality: Barrio San Agustin, Mt. Baloy. February 1987. R. Sison and L. Pelayo. PNM 1114. Island record.

Platymantis guentheri (Guenther's Forest Frog). Antique Province: Valderrama Municipality: Barrio San Agustin, Mt. Baloy, 950 m elev. 17 October 1989. J. W. Ferner. CMNH 3166. Island record.

SAURIA

Draco sp. (Flying Lizards). Aklan Province: Ibajay Municipality: Barrio Bugtong-bato. August 1983. CMNH 3237–3239 (PNM Field Nos. 367–370, 373, 375); Antique Province: Barbasa Municipality: Barrio Igapalge. August 1989. PNM Field Nos. 338-343; Iloilo Province: Viejo Municipality: Barotac Viejo, Sitio San Francisco. March 1988. CMNH 3240-3241 (PNM Field Nos. 344-346). R. Sison. Island record for genus. Currently, specific names are not reliable in this genus based on taxonomic revisions underway (R. I. Crombie, pers. comm.).

Hemidactylus stejnegeri (Stejneger's House Gecko). Iloilo Province: Dingle Municipality: Barrio Moroboro, Bulabog-Puti-an National Park, 100 m elev. 19 October 1989. R. Sison. CMNH 3225. Island record.

Gekko mindorensis (Mindoro Narrow-disked Gecko). Iloilo Province: Dingle Municipality: Barrio Moroboro, Bulabog Putiraan National Park, 100 m elev. 22 October 1989. R. Sison. PNM Field No. 2500. Island record.

Gonyocephalus sp. (Anglehead Lizards). Aklan Province: Libacao Municipality: Barrio Danao. February 1987. PNM 1130–1132. R. Sison and L. Pelayo. Island record for genus. Currently, specific names are not reliable in this genus based on revisions underway (see Ross and Gonzales 1991).

Mabuya indeprensa. Iloilo Province: Mt. Baloy. February 1987. CMNH 3247 (PNM 1151-1152). R. Sison and L. Pelayo. Antique Province: Valderrama Municipality: Barrio San Agustin, Mt. Baloy, 200 m elev. 4 October 1989. PNM Field No. 97. J. W. Ferner. Island record.

Sphenomorphus fasciatus (Banded Sphenomorphus). Antique Province: Valderrama Municipality: Barrio San Agustin, Mt. Baloy, 1200 m elev. 13 October 1989. CMNH 3248. R. Kennedy. Island record.

Tropidophorus grayi (Spiny Waterside Skink). Antique Province: Valderrama Municipality: Barrio Binanogan. 24 May 1989. PNM Field No. 96. R. Sison. Island record.

SERPENTES

Chrysopelea paradisi (Paradise Snake). Aklan Province: Ibajay Municipality: Barrio Bugtong-bato. 8 July 1983. PNM 1050. R. Sison. Island record.

Oligodon modestus (Spotted-bellied Short-headed Snake). Aklan Province: Libacao Municipality: Barrio Jamindang. March 1987. PNM 1066. R. Sison and L. Pelayo. Island record.

Dendrelaphis caudolineatus (Lined Slender Arboreal Snake). Antique Province: Valderrama Municipality: Barrio San Agustin, Mt. Baloy, 200 m elev. 1 October 1989. CMNH 3254. R. Sison. Island record.

Pseudorhabdion mcnamarae (McNamara's Burrowing Snake). Antique Province: Valderrama Municipality: Barrio San Agustin, Mt. Baloy, 950 m elev. 14 October 1989. PNM Field Nos. 163 and 209. R. Sison. Island record.

Acknowledgments.— We thank R. I. Crombie for his patient assistance as we became more familiar with Philippine herpetofauna. The logistical support for this project provided by R. S. Kennedy is greatly appreciated. Thanks to R. S. Kennedy, J. Cabalquinto, E. Canada, M. Ebreo, R. Fernandez, J. Lasugas, M. Manuel, and V. Samarita and numerous other assistants for their aid in the field. Financial support was generously provided by the Cincinnati Museum of Natural History and Thomas More College.

New Distributional Records of Amphibians and Reptiles from New Hampshire

As part of on-going surveys of the amphibians and reptiles of New England (Klemens 1993), a small collection of preserved amphibians and reptiles from New Hampshire was accumulated, representing both my efforts as well as those of several colleagues. Collections were deposited at the American Museum of Natural History (AMNH) and significantly augment Taylor's (1993) distribution maps of New Hampshire's herpetofauna. Identifications were verified by Darrel R. Frost.

CAUDATA

Ambystoma maculatum (Spotted Salamander). Sullivan Co: Cornish, pond E of Chase Cemetery near Rt. 12-A. 20 April 1986. R. P. Cook. AMNH 128996. First record from Sullivan County, documenting Taylor's (1993:23) unconfirmed "sighting reports."

Desmognathus f. fuscus (Northern Dusky Salamander). Rockingham Co: Seabrook, E of U. S. Rt. 1, S of Seabrook Station. 29 March 1986. R. P. Cook. AMNH 128997. First record from Rockingham County and first documentation of this species' occurrence in New Hampshire's coastal region (Taylor 1993:26).

Plethodon cinereus (Redback Salamander). Sullivan Co: Cornish. 15 May 1986. R. P. Cook. AMNH 129021. First record from Sullivan County (Taylor 1993:29).

ANURA

Hyla versicolor (Gray Treefrog). Sullivan Co: Cornish, pond E of Chase Cemetery near Rt. 12-A. 25 May 1986. R. P. Cook. AMNH 129050. First record from Sullivan County (Taylor 1993:36).

Pseudacris c. crucifer (Northern Spring Peeper). Sullivan Co: Cornish, E of Rt. 12-A, ca. 0.25 mi. N Chase Cemetery. 18 April 1986. R. P. Cook. AMNH 129048–49. First record from Sullivan County documenting Taylor's (1993:37) unconfirmed "sighting reports."

TESTUDINES

Chelydra s. serpentina (Common Snapping Turtle). Grafton Co: Landaff, trib. to Pearl Lake, 1020 feet elev. 27 June 1982. M. W. and N. S. Klemens. AMNH 124936. Extends New Hampshire range 15 miles NNE from Grafton County record mapped by Taylor (1993:46).

Chrysemys picta (Painted Turtle). Grafton Co: Landaff, Chandler Pond, 1100 feet elev. 27 June 1982. M. W. and N. S. Klemens. AMNH 124937–38. Extends New Hampshire range 30 miles NNE from southern Grafton County record mapped by Taylor (1993:50).

SERPENTES

Lampropeltis t. triangulum (Eastern Milk Snake). Carroll Co: ca. 5 mi. N Center Sandwich on Maple Ridge Road. 17 June 1967. H. J. Greer. AMNH 100394. First record from Carroll County documenting Taylor's (1993:61) unconfirmed "sighting report."

Lampropeltis t. triangulum (Eastern Milk Snake). Grafton Co: Landaff, near Merrill Mountain Road. 29 June 1982. E. Twaronite. AMNH 124942. First record from Grafton County (Taylor 1993:61).

Nerodia s. sipedon (Northern Water Snake). Merrimack Co: Warner, near wooded inlet stream to Ballard Brook above Joppa Road. 5 February 1991. D. Carroll. AMNH 137472. Extends New Hampshire range 25 miles W from record near Rockingham-Merrimack county line mapped by Taylor (1993:54).

Acknowledgments.—David Carroll, Robert P. Cook, Mary Hake, Josephine Kelleher, Nicole S. Klemens, and Eugene Twaronite provided specimens and/or assistance with New Hampshire field work. All collections were made under the provisions of scientific collecting permits issued by the New Hampshire Fish and Game Department.

Recent Distribution Records for Amphibians and Reptiles in Illinois

Since Smith's (1961, Bull. Illinois Nat. Hist. Surv. 28:1–298) comprehensive work on the amphibians and reptiles of Illinois, a number of short articles have reported new information on the distribution of some Illinois species. Many of these articles treated individual species, frequently those uncommon in the state or secretive (e.g., *Hemidactylium scutatum, Scaphiopus holbrookii, Ophisaurus attenuatus, Clonophis kirtlandii*). Several short articles provided blocks of new distribution information for multiple species, for example, Holman (1966, Trans. Illinois State Acad. Sci. 59:298–300), Moll (1962, Herpetologica 18:207–209), Moll et al. (1977, Herpetol. Rev. 8:85), Morris (1976, Herpetol. Rev. 7:126–127), Munyer and Parmalee (1967, Trans. Illinois State Acad. Sci. 60:200–202), Schramm and Nordgren (1977, Trans. Illinois State Acad. Sci. 70:243) and Thurow and Sliwinski (1991, Bull. Chicago Herpetol. Soc. 26:129–132). The bibliography of Illinois herpetological literature from 1960 to 1980 (Morris et al. 1983, Bull. Illinois Nat. Hist. Surv. 33:123–138) included distribution records during that period.

Some Illinois counties for which Smith had few records have remained poorly known. Even some species considered to be com-

mon statewide or common in surrounding regions are undocumented for those counties (e.g., Boone, Clinton, Fayette, and JoDaviess).

This article includes new county records and recent records for several species in disjunct portions of their Illinois ranges. Several vouchers are included to confirm literature records not previously documented. Vouchers have been deposited in the herpetology collections of the following institutions: Illinois Natural History Survey (INHS, verified by C. Phillips); Milwaukee Public Museum Photo Collection (MPM, verified by G. S. Casper), and Southern Illinois University at Carbondale, Department of Zoology (SIUC, verified by R. A. Brandon).

CAUDATA

Ambystoma laterale (Blue-spotted Salamander). DuPage Co: Wood Dale Grove Forest Preserve, North Conservation Area (NW 1/4 Sec. 22, T40N, R11E). 14 April 1987. M. Redmer. INHS 10800. Darien, near 91st Street and Rt. 83 (SW 1/4 Sec. 2, T37N, R11E). 4 June 1989. M. Redmer. SIUC H-3805. Specimens confirm previous literature records (Jessup 1981, Bull. Chicago Herpetol. Soc. 16:44–46; Mierzwa 1987, Bull. Chicago Herpetol. Soc. 22:121; Ludwig et al. 1992, Trans. Illinois State Acad. Sci. 85:187–199) in which no vouchers were mentioned.

Ambystoma maculatum (Spotted Salamander). Monroe Co: 5.8–7.1 km N Randolph County line on Prairie du Rocher/Valmeyer Road (T4S, R10W). 3 April 1991. R. A. Brandon and S. R. Ballard. SIUC H-4265–69. Pinkle's Woods along Bluff Road (NE 1/4 Sec. 22, T3S, R11W). 23 March 1993. M. Redmer. SIUC H-4435. New county record.

Ambystoma t. tigrinum (Eastern Tiger Salamander). Boone Co: pond near Kishwaukee River at Lawrenceville Road (SW 1/4 Sec. 30, T44N, R4E). 30 July 1988. M. Redmer. INHS 10804. New county record.

Eurycea longicauda melanopleura (Dark-sided Salamander). Jersey Co: Pere Marquette State Park, tributary of Graham Hollow (northern Sec. 7, T6N, R12W). 4 July 1991. R. A. Brandon, D. Brandon, S. R. Ballard and J. Howard. SIUC H-4437. New county record.

Siren intermedia nettingi (Western Lesser Siren). Fayette Co: 0.8 km E Hurricane Creek on County Road 800N (SW 1/4 Sec. 19, T5N, R1W). 8 May 1993. S. R. Ballard, A. Jones, B. Jones. SIUC H4448-49. New county record.

ANURA

Scaphiopus h. holbrookii (Eastern Spadefoot). Pope Co: New Liberty, 0.6 km NW jct. Unionville Road on Bay City Road (NE 1/4 Sec. 17, T16S, R7E). 31 July 1993. M. Redmer. SIUC H-4440. Documents county record of Thompson et al. (1968, Trans. Illinois State Acad. Sci. 61:427) for which no vouchers exist (R. A. Brandon, pers. comm.). Williamson Co: Wolf Creek, on Wolf Creek Road, 1.1 km S Palestine Church (NW 1/4 Sec. 36, T10S, R1E). 20 September 1992. M. Redmer. SIUC H-4150. New county record; northernmost record for central Shawnee Hills.

Gastrophryne carolinensis (Eastern Narrowmouth Toad). Pope Co: small pond NE of Golconda (SE 1/4 Sec. 9, T12S, R7E). 11 August 1992. D. Spivey. SIUC H-4103. 1.6 km W New Liberty (western Sec. 17, T16S, R7E). 22 June 1991. S. J. Karsen. SIUC H-4107. New county record.

Bufo a. americanus (Eastern American Toad). Boone Co: Kishwaukee River at Piscasaw Creek (SW 1/4 Sec. 30, T44N, R4E). 30 July 1988. M. Redmer. INHS 10810-811. New county record; Lee Co: Green River Conservation Area, S shore of Atkinson Road Marsh (NW 1/4 Sec. 13, T19N, R8E). Pump Factory Road, across flooded field from Area 6 parking lot (SE 1/4 Sec. 18, T19N, R9E). 7 April 1991. M. Redmer. SIUC H-4082 and H-4075, respectively. Franklin Creek State Park, NW portion, Twist Road across from park office (NE 1/4 Sec. 33, T22N, R10E). 6 April 1991. M. Redmer. SIUC H-4080. New county record.

Hyla chrysoscelis (Cope's Gray Treefrog). Lee Co: Nachusa Grasslands, fen area (NW 1/4 Sec. 21, T22N, R10E). 15 May 1988. M. Redmer, J. Levell. MPM P-148. New county record identified by sonogram (on file at MPM).

Hyla cinerea (Green Treefrog). Massac Co: Mermet Lake Conservation Area (NW 1/4 Sec. 35, T14S, R3E). 17 June 1989. S. J. Karsen. SIUC H-3777. New county record; Pope Co: ca. 1.6 km W New Liberty on Unionville Road (SW 1/4 Sec.17, T16S, R7E). 22 July 1993. M. Redmer, R. A. Brandon, M. Bavetz. SIUC H-4450. Next to Barren Creek on Bay City Road just west of bridge (NE 1/4 Sec. 35, T14S, R6E). 31 July 1993. M. Redmer. SIUC H-4442. Smithland Locks and Dam Road, 0.1–0.3 km W Army Corps buildings (SE 1/4 Sec. 33 T15S, R7E). 31 July 1993. M. Redmer. SIUC H-4443–47. New county record; SE most records in state; Williamson Co: Crab Orchard National Wildlife Refuge, Spillway Road swamp (SW 1/4 Sec. 4, T10S, R1E). 10 July 1992. M. Redmer. SIUC H-4102. New county record; extends range ca. 17–20 km NE of previous records in SW Jackson County.

Hyla versicolor (Gray Treefrog). DuPage Co: Waterfall Glen Forest Preserve, Bluff Road Pond (SW 1/4 Sec. 11, T37N, R11E). 21 May 1988. M. Redmer. MPM P-149. Identified by sonogram (on file at MPM); confirms previous literature record for county (Ludwig et al. 1992, Trans. Illinois State Acad. Sci. 85:187–199).

Pseudacris c. crucifer (Northern Spring Peeper). Franklin Co: ca. 2 km SW Zeigler (NW 1/4 Sec. 26, T7S, R1E). 28 March 1989. M. Redmer. SIUC H-3430. New county record; Lee Co: Nachusa Grasslands fen (NW 1/4 Sec. 21, T22N, R10E). 15 May 1988. M. Redmer. MPM P-150. Franklin Creek State Park, NW side, Twist Road pond (NE 1/4 Sec. 33, T22N, R10E). 6 April 1991. M. Redmer. SIUC H-4067–68. New county record; continues sporadic distribution in northern Illinois; Massac Co: S of New Columbia (SW 1/4 Sec. 16, T14S, R4E). 25 March 1989. M. Redmer. SIUC H-3435–36. New county record; Perry Co: Pyramid State Park (NW 1/4 Sec. 14, T6S, R3W). 24 March 1989. M. Redmer. SIUC H-3431–32. New county record; Washington Co: Washington County Conservation Area (SE 1/4 Sec. 7, T2S, R2W). 24 March 1989. M. Redmer. SIUC H-3433–34. New county record.

Pseudacris t. triseriata (Western Chorus Frog). Lee Co: Green River Conservation Area, flooded field at Hunting Area 3 (NW 1/4 Sec. 18, T19N, R9E). 5 April 1991. M. Redmer. SIUC H4071–72. Franklin Creek State Park, Twist Road Pond (NE 1/4 Sec. 33, T22N, R10E). 6 April 1991. M. Redmer. SIUC H-4070. New county record.

Rana catesbeiana (Bullfrog). Boone Co: Kishwaukee River at Piscasaw Creek confluence (SW 1/4 Sec. 30, T44N, R4E). 18 July 1988. M. Redmer. INHS 10807–08. New county record; Marshall Co: 0.8 km N Woodford/Marshall County line on Rt. 26 (NE 1/4 Sec. 34, T29N, R3W) and 1.8 km N Woodford/Marshall County line on Rt. 26 (NE 1/4 Sec. 27, T29N, R3W). 19 and 20 June 1990. S. R. Ballard. SIUC H-3948–49 respectively. New county record.

Rana clamitans melanota (Green Frog). Marshall Co: 0.8 km N Woodford/Marshall County line on Rt. 26 and along RR Tracks (NW 1/4 Sec. 35, T29N, R3W). 20 June 1990. S. R. Ballard and D. Ferrari. SIUC H-3950–52. New county record; Randolph Co: Kaskaskia Island, in Old River under St. Mary's Bridge (SE 1/4 Sec. 8, T7S, R10E). 30 April 1989. M. Redmer. SIUC H-3437. New county record; first Illinois record from west of the Mississippi River.

Rana palustris (Pickerel Frog). Randolph Co: 0.4 km S Monroe/Randolph County line on Prairie du Rocher-Valmeyer Road. 11 April 1991. S. R. Ballard. SIUC H-4270. New county record; St. Clair Co: Imbs Road, ca. 1.8 km SW Zion Church and 2.5 km NE Phelps (NW 1/4 Sec. 26, T1N, R10W). 7 April 1993. M. Redmer. SIUC H-4428. Verifies old literature record (Hurter 1893, St. Louis Acad. Sci. Trans. 6:251–261, cited by Smith 1961, Bull. Illinois Nat. Hist. Surv. 28:1–298).

TESTUDINES

Chelydra s. serpentina (Common Snapping Turtle). Lee Co: Rt. 26, 1.1 km N of Union Road (SE 1/4 Sec. 4, T19N, R9E). 23 June 1991. M. Redmer. SIUC R-2349. New county record; Stephenson Co: Le-Aqua-Na State Park, Waddams Creek at picnic area (NW 1/4 Sec. 17, T28N, R6E). 28 July 1991. M. Redmer. SIUC R2302. New county record.

Sternotherus odoratus (Common Musk Turtle). Franklin Co: ca. 2 km SW Zeigler (NE 1/4 Sec. 27, T7S, R1E). 28 September 1988. M. Redmer and S. J. Karsen. SIUC R-2081. New county record; Pulaski Co: 2 km SSE Perks (Sec. 14, T14S, R1E). 13 May 1986. R. A. Brandon and M. A. Morris. SIUC R-2122. New county record; Whiteside Co: Mississippi River, ca. 3 km upstream from Lock and Dam 13 (NE 1/4 Sec. 2, T22N, R3W). 3 September 1987. M. Redmer. SIUC R-2475. New county record; confirms presence in NW Illinois (Conant and Collins 1991, A Field Guide to the Reptiles and Amphibians of Eastern and Central North America. 3rd Edition. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Kinosternon subrubrum (Eastern Mud Turtle). Gallatin Co: 2.4 km N Saline Mines (northern Sec. 23, T10S, R9E). 25 March 1991. S. R. Ballard and R. A. Brandon. SIUC R-2476. New county record; Perry Co: 2.2 km E DuQouin on RR tracks in Reese Creek Bottoms (NE 1/4 Sec. 15, T6S, R1W). 7 April 1993. S. J. Karsen. SIUC R-2481. New county record.

Chrysemys picta (Painted Turtle). Boone Co: Genoa Road at Kishwaukee River (SW 1/4 Sec. 30, T44N, R4E). 30 July 1988. M. Redmer. INHS 10816. New county record; Greene Co: Rt. 108, 6.1 km W jct. Rt. 267 (NW 1/4 Sec. 19, T10N, R12W). 24 July 1993. S. R. Ballard. SIUC R-2480. New county record; Lee Co: Rt. 26 at Union Road (SW 1/4 Sec. 10, T19N, R9E). 19 May 1991. M. Redmer. SIUC R-2337. Franklin Creek State Park, NW portion, on Twist Road (NE 1/4 Sec. 33, T22N, R10E). 22 June 1991. M. Redmer. SIUC R-2454. New county record; Perry Co.: 3.2 km E DuQuoin on Rt. 14 (NW 1/4 Sec. 27, T6S, R1W). 2 October 1988. R. G. Weck. SIUC R-2143. New county record; fills in gap between Randolph, Washington, Jefferson, Franklin and Jackson counties.

Graptemys geographica (Common Map Turtle). DuPage Co: Warrenville Grove Forest Preserve, below dam (NE 1/4 Sec. 3, T39N, R9E). 17 July 1989. M. Redmer. SIUC R-2482. Confirms literature record (Ludwig et al. 1992, Trans. Illinois State Acad. Sci. 85:187–199).

Terrapene c. carolina (Eastern Box Turtle). Randolph Co: 3.2 km N of Rockwood on Rt. 3 (SW 1/4 Sec. 2, T8S, R6W). 22 July 1988. R. G. Weck. SIUC R-2232. New county record; fills in gap between Monroe and Jackson counties.

Apalone s. spinifera (Eastern Spiny Softshell). Lee Co: Green River at Rt. 26 bridge (NW 1/4 Sec. 4, T19N, R9E). 4 May 1991. M. Redmer. SIUC R-2315. New county record; fills gap between Whiteside, Ogle, and Bureau counties.

SAURIA

Cnemidophorus s. sexlineatus (Six-lined Racerunner). Pulaski Co: near Karnak (NE 1/4 Sec. 15, T14S, R2E). 12 July 1989. S. Karsen. SIUC R-2169. New county record.

SERPENTES

Coluber constrictor (Racer). Hardin Co: Karber's Ridge Road, 1.5 km NE jct. Rt. 34 (SE 1/4 Sec. 11, T11S, R7E). 26 May 1990. S. R. Ballard. SIUC R-2221. New county record, fills gap between Pope and Gallatin counties; Lee Co: Green River Conservation Area Hunting Area 2 (SE 1/4 Sec. 7, T19N, R9E). 4 June 1991. M. Bavetz, R. Flick, M. Redmer, R. A. Brandon. SIUC R-2339. New county record; Madison Co: Sand Road in Poag, just E jct. with Poag Road (SW 1/4 Sec. 18, T4N, R8W). 5 October 1993. S. R. Ballard. SIUC R-2492. New county record.

Elaphe v. vulpina (Western Fox Snake). Boone Co: ca. 2 km NW Caledonia, Greenlee Road at RR Tracks (NW 1/4 Sec. 17, T45N, R3E). 5 September 1988. M. Redmer. INHS 10809. New county record; JoDaviess Co: 0.5 km N Carroll/JoDaviess County line on Rt. 84 (SW 1/4 Sec. 36, T26N, R2E). 26 May 1989. M. Redmer. SIUC R-2207. New county record and NW most record in state; Lee Co: Green River Conservation Area, Maytown Road 0.3 km E Pump Factory Road (SW 1/4 Sec. 17, T19N, R9E). 20 May 1991. M. Redmer. SIUC R-2343. New county record; Warren Co: 2 km NE Roseville on County Road 900N at R. Killy Farm (south-central Sec. 16, T9N, R2W). 5 June 1993. M. Redmer. SIUC R-2471. New county record.

Farancia abacura reinwardtii (Western Mud Snake). Pope Co: 1.2 km W New Liberty (center of Sec. 17, T16S, R7E). 13 July 1991. S. J. Rarsen. SIUC R-2474. New county record.

Heterodon platirhinos (Eastern Hognose Snake). Whiteside Co: Fulton-Thompson Sand Prairie Nature Preserve, 4.5 km N Fulton (NW 1/4 Sec. 1, T22N, R3E). 3 September 1987. M. Redmer.

MPM P-131. New county record; St. Clair Co: Milstadt. May 1979 and May 1981. R. Young and R. Besse. SIUC R-1862–63 respectively. New county record.

Lampropeltis c. calligaster (Prairie Kingsnake). Johnson Co: Goreville (Sec. 22, T11S, R2E). 3 October 1989. S. Henning. SIUC R-2213. Confirms literature record (Klimstra and Hutchison 1965, Trans. Illinois State Acad. Sci. 58:151–156) for which no vouchers exist (R. A. Brandon, pers. comm.). Fills gap between Union, Williamson, Pope and Massac counties.

Lampropeltis t. triangulum (Eastern Milk Snake). Woodford Co: 1.6 km E Rt. 26, off upper Spring Bay Road, near Woodford/Tazewell county line (eastern Sec. 36, T27N, R4W). D. Holmes. SIUC R-2483. New county record.

Nerodia r. rhombifer (Diamondback Water Snake). Gallatin Co: cypress ditch 5 km W Shawneetown (NW 1/4 Sec. 20, T9S, R9E). 10 June 1989. S. J. Karsen. SIUC R-2214. New county record.

Nerodia sipedon pleuralis (Midland Water Snake). Massac Co: Mermet Lake Conservation Area (NW 1/4 Sec. 35, T14S, R3E). 17 June 1989. S. J. Karsen. SIUC R-2215. New county record; fills gap between Pulaski, Johnson and Pope counties.

Nerodia s. sipedon (Northern Water Snake). Boone Co: at confluence of Kishwaukee River and Piscasaw Creek (SW 1/4 Sec. 30, T44N, R9E). 3 July 1989. M. Redmer. SIUC R-2412. New county record; Whiteside Co: S entrance to Morrison-Rockwood St. Park (south-central Sec. 16, T21N, R2W). 5 June 1993. M. Redmer. SIUC R-2470. New county record.

Opheodrys aestivus (Rough Green Snake). Massac Co: Mermet Lake Conservation Area, W side of lake (Sec. 35, T14S, R3E). 6 May 1988. W. D. Robinson. SIUC R-2024. New county record; Pulaski Co: Belknap Road at Cache River, N of Karnak (NE 1/4 Sec. 15, T14S, R2E). 16 June 1988. R. A. Brandon, R. G. Weck and S. R. Ballard. SIUC R-2009. New county record.

Opheodrys vernalis (Smooth Green Snake). Lee Co: Green River Conservation Area, dirt road 0.5 km W Hunting Area 2 parking lot (SE 1/4 Sec. 7, T19N, R8E). 20 May 1991. M. Redmer. SIUC R2340. Franklin Creek State Park, Twist Road Pond (NE 1/4 Sec. 33, T22N, R10E). 22 June 1991. M. Redmer. SIUC R-2346. New county record.

Pituophis catenifer sayi (Bullsnake). Marshall Co: 0.8 km N Woodford/Marshall County line along RR tracks at Rt. 26 (NW 1/4 Sec. 35, T29N, R3W). 18 June 1992. S. R. Ballard. SIUC R-2479. New county record.

Regina septemvittata (Queen Snake). Ogle Co: White Pines Forest State Park, NW tributary to Pine Creek (NE 1/4 Sec. 8, T23N, R9E). 14 July 1991. M. Redmer. SIUC R-2300. Third record from Rock River Drainage, first record W of Rock River and NW most record in range of the species in Illinois (Smith 1961, Bull. Illinois Nat. Hist. Surv. 28:1–298; Anton and Redmer 1991, Herpetol. Rev. 24:26).

Storeria dekayi wrightorum (Midland Brown Snake). Boone Co: Riverside Road at Beaver Creek (SE 1/4 Sec. 5, T44N, R3E). 30 July 1988. M. Redmer. INHS 10815. New county record; Carroll Co: Mississippi Palisades State Park, near RR tracks (SW 1/4 Sec. 21, T25N, R3E). 26 May 1989. M. Redmer. SIUC R-2209. New county record and NW most record in state; Clinton Co: Eldon Hazlet State Park, DOR on blacktop road 0.4 km E park office (NW 1/4 Sec. 33, T3N, R2W). 16 October 1993. S. R. Ballard. SIUC R-2493. New county record; Fayette Co: DOR on County Road 450N, 0.08 km W jct. with County Road 60E (central Sec. 7, T4N, R1W). 23 October 1993. S. R. Ballard. SIUC R-2496. New county record; Lee Co: Nachusa Grasslands, oak savanna (NW 1/4 Sec. 21, T22N, R10E). 15 May 1988. M. Redmer. MPM P-153. Franklin Creek State Park, NW portion along Twist Road, 0.4 km N park office (NE 1/4 sect33, T22N, R10E). 22 June 1991. M. Redmer. SIUC R-2295. Green River Conservation Area, Maytown Road at Parking Area 10 (SE 1/4 Sec. 13, T19N, R8E). 29 June 1991. M. Redmer. SIUC R-2341. New county record; Pope Co: 5 km SW New Liberty (NW 1/4 Sec. 35, T16S, R7E). 17 June 1989. S. J. Karsen. SIUC R-2216. New county record; fills gap between Johnson and Hardin counties.

Storeria o. occipitomaculata (Northern Redbelly Snake). Carroll Co: Mississippi Palisades State Park near RR tracks (SW 1/4 Sec. 21, T25N, R3E). 26 May 1989. M. Redmer. SIUC R-2210. New county record, NW most locality in state, and confirms presence of species in NW Illinois (Smith 1961, Bull. Illinois Nat. Hist. Surv. 28: 1–298; Conant and Collins 1991, A Field Guide to the Reptiles and Amphibians of Eastern and Central North America. 3rd Edition. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.); Jersey Co: Pere Marquette State Park, Trail 9 (NE 1/4 Sec. 10, T6N, R13W). 22 June 1991. R. A. Brandon, D. Brandon, S. Ballard and J. Petzing. SIUC R-2473. New county record.

Thamnophis r. radix (Eastern Plains Garter Snake). Boone Co: along Lawrenceville Road near confluence of Kishwaukee River and Piscasaw Creek (SW 1/4 Sec. 30, T44N, R4E). 30 July 1988. M. Redmer. INHS 10812. New county record.

Thamnophis s. sirtalis (Eastern Garter Snake). Clinton Co: DOR on County Road 1840E, 1.1 km N jct. with County Road 1430N (central Sec. 7, T2N, R2W). 23 October 1993. S. R. Ballard. SIUC R2497. New county record; Johnson Co: ca. 1.6 km E West Vienna on Rt. 146 (east-central Sec. 33, T12S, R2E). 19 May 1988. R. A. Brandon and S. R. Ballard. SIUC R-2148-49. New county record, filling gap between Union, Williamson, Pope and Pulaski counties; Saline Co: 0.8 km SE Eldorado (Sec. 27, T8S, R7E). 12 October 1974. M. Anderson and K. Anderson. SIUC R-1860. New county record.

Agkistrodon contortrix mokasen (Northern Copperhead). Saline Co: 1.6 km W Horseshoe (Sec. 34, T10S, R7E). 22 September 1990. S. J. Karsen. SIUC R-2477. New county record. Franklin Co: (SE 1/4 Sec. 33, T5S, R4E). 20 August 1992. R. Hutchcraft. SIUC R-2478. New county record.

Crotalus horridus (Timber Rattlesnake). Pope Co: nine-day trail ride to One Horse Gap Lake (SE 1/4 Sec. 32, T11S, R7E). 18 May 1990. E. Steward Work Camp Crew. SIUC R-2220. New county record; fills gap between Johnson and Hardin counties.

Acknowledgments.—We thank R. A. Brandon, Southern Illinois University at Carbondale, for commenting on the manuscript and for his constant advice and encouragement. For permission to collect we thank the Illinois Department of Conservation, the United States Fish and Wildlife

Service (Crab Orchard National Wildlife Refuge), the United States Forest Service (Shawnee National Forest), and the Forest Preserve District of DuPage County. Several individual collectors donated specimens reported herein to the herpetology collection, Department of Zoology, Southern Illinois University at Carbondale. S. J. Karsen accompanied MR in the field on many occasions and made considerable donations of specimens to the SIUC collection.

Portions of the field work were funded by the Illinois Endangered Species Protection Board and Illinois Department of Conservation (Nongame Wildlife Conservation Fund contracts to R. A. Brandon). Lee County photo vouchers were taken during a 1987 Chicago Herpetological Society field trip organized by K. S. Mierzwa.

BOOK REVIEWS

Biology of Whiptail Lizards (Genus *Cnemidophorus*), John W. Wright and Laurie J. Vitt (editors). 1993. The Oklahoma Museum of Natural History: i–xiv + 417 pp. Hardcover. US $29 plus shipping. ISBN 1-883090-01-6.

This volume is the outcome of a symposium devoted to the teiid genus *Cnemidophorus*. The symposium—conceived and organized by John W. Wright and held at the University of Oklahoma in August 1984 during the joint annual meetings of the American Society of Ichthyologists and Herpetologists, the Herpetologists' League, and the Society for the Study of Amphibians and Reptiles—brought together a diverse assemblage of over 50 specialists who presented 30 papers on a broad spectrum of topics related to *Cnemidophorus*. The resulting volume (The Herpetologists' League Special Publication No. 3), containing 15 separate papers by 22 authors, is dedicated to Charles H. Lowe and Richard G. Zweifel. Contributions have been revised and updated with additional findings through September 1992. The individual papers are not grouped under subject headings, but the topics covered include systematics, reproduction, physiology, behavior, ecology, and community level analyses. Not surprisingly, a pervasive topic is the differences and similarities between unisexual and bisexual species in aspects of their biology.

The preface by John Wright and Laurie Vitt explains that the decision to produce this volume was not reached until after the symposium, and that some of the symposium presentations were already in press or committed to be published elsewhere by that time. Included in the preface is a list of the authors and titles of all 30 papers that were presented at the symposium, as well as a list of 12 symposium papers that were published elsewhere and are thus not included in the present volume.

The first chapter is an introduction by Charles H. Lowe which provides an historical review of taxonomy and systematics of *Cnemidophorus* organized to cover three time periods from 1830 to 1990. Lowe's chronological presentation recounts the considerable difficulties and confusion experienced by workers attempting to discriminate taxa and discusses the major contributions during each time period that led to our current understanding of the genus. In the author's opinion, one of the most significant breakthroughs in discriminating *Cnemidophorus* taxa was the description of *C. neomexicanus* by Lowe and Zweifel (1952). For the first time, in addition to appearance in life and ecological information gathered in the field, discrimination of a *Cnemidophorus* species was based on statistical analysis of quantitative meristic data. The author further reviews the impact on *Cnemidophorus* research of the discovery of parthenogenesis in *Lacerta* by Darevsky, and more recently, the high level of taxonomic resolution achieved through chromosomal and molecular studies.

In Chapter 2, John W. Wright provides a summary of the evolutionary relationships of *Cnemidophorus* and a taxonomic arrangement partitioned into six species groups. The composition of each group is discussed and distribution maps and color photographs of representative taxa are provided. Wright reviews the origin and evolution of parthenogenesis in *Cnemidophorus* as well as the controversies surrounding nomenclature of parthenogenetic taxa. The lineages of parthenogenetic taxa are reviewed by species group, with particular reference to the results of mitochondrial DNA analyses. An alphabetical listing of the groups and their respective members, which contains over 100 taxa and includes over a dozen undescribed forms, differs substantially from the recent taxonomic arrangement of Maslin and Secoy (1986).

The next five papers present results of field investigations and literature reviews on the interrelated subjects of foraging ecology, thermoregulation, activity patterns, and locomotion.

Roger Anderson investigated foraging ecology of *Cnemidophorus tigris* at a six-hectare site in the Sonoran Desert of Riverside County, California, through systematic time-constrained field observations of foraging animals and quantitative assessments of vegetation, prey availability, and stomach contents. At this site, *C. tigris* was determined to be a wide forager that depended primarily on chemoreception to detect fossorial and hidden prey, but relied on vision to choose foraging pathways between and within patches of widely dispersed microhabitats. The results indicate that successful foraging in *C. tigris* is clearly not the result of opportunistic success during random wanderings.

Using experimental chambers, Richard Bowker explored questions relating to the brief daily activity periods of *C. exsanguis* and *C. velox* and the costs of their wide-foraging lifestyles by examining temperature regulation and the influence of water loss on activity times. Bowker discusses the relationships between maintaining precisely regulated body temperatures, the costs of activity, and the increase in water loss with increase in body temperature. The activity experiments indicated that water loss was proportional to length of activity, and Bowker concludes that water may be an important factor limiting daily activity in these animals.

Gustavo Casas-Andreu and Marco Gurrola-Hidalgo report on the comparative ecology of *C. communis* and *C. lineatissimus* at a tropical deciduous forest site in Jalisco, México. Average body temperatures for both species are slightly lower than those reported in a number of studies on *Cnemidophorus* from the southwestern United States, and daily activity patterns were unimodal, with greatest activity at mid-day during the entire year. Similar unimodal activity patterns have been found for other species of tropical tei-

ids, whereas bimodal activity patterns are reported for lizards from the southwestern United States.

Kay Etheridge and Lawrence Wit examine the comparatively short active season and the resulting long inactive period of adult *C. sexlineatus* in Alabama and discuss evidence from the literature and their own field work regarding the factors affecting this activity cycle. They conclude that the short annual activity period of *C. sexlineatus* can be attributed to a lack of territorial behavior, their wide-ranging foraging behavior and high foraging efficiency, avoidance of negative energy returns when food is scarce, and reduction of the risk of predation.

Locomotor performance and activity metabolism of *C. tigris* are reviewed by Theodore Garland and compared to the available quantitative data for other species of lizards. Results from the laboratory work reported here show that the endurance capacity of *C. tigris* is exceptionally high in comparison to that of other lizards, and appears to exceed what is required for foraging alone. Garland concludes that while the primary adaptive significance of high endurance capacity in *C. tigris* is unclear, a variety of activities other than foraging that may require high endurance capacities must be considered. Garland points out that the available comparative information is very limited and that additional data on other arid habitat *Cnemidophorus* are needed. Also, performance capacities demonstrated in the laboratory need to be compared to findings from the field.

The contributions by Vitt and Breitenbach, Trauth and Fagerberg, and Crews and Moore provide information on reproduction in *Cnemidophorus*. Laurie Vitt and Gary Breitenbach present an exhaustive review and synthesis of literature on reproduction and life histories of *Cnemidophorus*, emphasizing ecological aspects of reproduction. They compiled literature information on reproductive characteristics of 17 species of *Cnemidophorus* and a list of over 50 *Cnemidophorus* populations from which the reproductive data were obtained. The authors examine the available information on clutch size and egg mass, seasonality in reproduction and clutch frequency, geographic and temporal variation in reproduction, and female investment to provide support for five postulated differences in reproductive characteristics that would be expected between *Cnemidophorus* and typical wait-and-ambush lizard species.

Stanley Trauth and Wayne Fagerberg looked at eggshell ultrastructure of oviducal eggs from the hybrid species *C. laredoensis* compared with the eggshell morphology of *C. sexlineatus*, one of its parent species. In light of the results, the authors discuss the potential application of stereological methods for resolving eggshell ultrastructure in order to detect inter- and/or intraspecific differences in eggshells and as a means of correlating local environmental conditions of nest sites.

The paper by David Crews and Michael Moore provides an update on the ongoing investigations into the psychobiology of parthenogenetic whiptails and describes the relationship between pseudocopulatory behavior, hormonal correlates, and the ovarian cycle in *C. uniparens*. The authors also defend their interpretations of the causes and functions of pseudocopulatory behavior in parthenogenetic *Cnemidophorus* in light of contentions that pseudocopulation is an artifact of crowding in captivity and that reproductive condition is not associated with behavioral roles during pseudocopulation.

Thyroid activity and metabolic rate in *C. sexlineatus* were studied by Lawrence Wit and Jeffrey Sellers using animals caught from the wild over a 16-month period in Alabama and Georgia. They suggest that the lowered metabolic rate and elevated plasma thyroxine titers found in hibernating animals are not simply consequences of the animals becoming dormant in response to cold temperatures. The authors conclude that the increase in plasma thyroxine is due to decreased peripheral use of the hormone, as indicated by oxygen consumption, rather than increased production.

Beth Leuck's analysis of aggressive behavior between sympatric diploid and triploid *C. tesselatus* represents an insightful approach designed to investigate the effects of genetic relatedness on aggressive behavior. Under experimental conditions, lizards in mixed diploid and triploid trials had significantly more aggressive acts towards each other than those of the same ploidy level. Based on these results, Lueck concludes that diploid and triploid *C. tesselatus* appear able to distinguish genetic relatedness.

Three papers focus on competitive interactions and resource partitioning in communities with bisexual and parthenogenetic whiptail species. Joseph Schall studied a community of five *Cnemidophorus* species, two parthenogenetic and three bisexual, in southwestern Texas to test the hypothesis that all-female species should use a broader range of habitats and resources, have more patchy distributions, and live in more disturbed areas. The two parthenogenetic species, *C. exsanguis* and *C. tessealatus*, had microhabitat niche breadths approximately 25% larger than the three bisexual species and were found in a much broader range of macrohabitat types, but they were most common in disturbed areas. However, he found no evidence of a difference in diet between the bisexual and parthenogenetic species.

The remaining two papers report on field studies in southern New Mexico that employed experimental population manipulations to examine mechanisms of coexistence between *C. tigris* and a sympatric unisexual whiptail. As part of a nine-year study, Orlando Cuellar monitored the immigration of *C. tigris* into an open sandy field from which *C. uniparens* was being systematically removed. The density of *C. tigris* at the site increased after removal of *C. uniparens* but decreased when the latter was no longer being removed. Cuellar concludes that the parthenogenetic species was excluding the bisexual through competition, and that parthenogenetic and bisexual whiptails coexist by inhabiting neighboring but distinct microhabitats.

Andrew Price, Joseph Lapointe, and Wirt Atmar removed *C. tigris* from one of three study grids and *C. tesselatus* from another, with the third grid serving as a control. Because there was no change in habitat use, their results indicated no microhabitat segregation between the two species. Further, there was no measurable response by the parthenogenetic *C. tesselatus* through either recruitment or increased reproduction to the removal of *C. tigris*.

The book measures 6 x 9 inches and is printed on nonreflective paper in easy-to-read, single column format. It contains numerous text figures, six distribution maps, and 48 color photographs of representative taxa in six *Cnemidophorus* species groups, including some not previously illustrated. Literature citations are placed at the end of each paper, whereas an index to subject matter and scientific names was compiled for the entire volume.

The book suffers from a number of flaws in editing and production. There are numerous typographical errors in the text. In addition, there are egregious omissions and errors with respect to tables and figures. The most obvious omissions include a reference to table 2 on p. 57 when only table 1 is present in chapter 2. Also, table 3 is absent from chapter 8 although it is referenced once on p. 221 and twice on p. 225. In chapter 2, the legends for figures 5, 7, 9, 11, and 13 all refer to figure 2 for specimen references but none are provided with figure 2; the legend for figure 3

does give information for specimens from the Natural History Museum of Los Angeles County, but does not have museum information for the acronyms listed in the other figure legends. An incorrect legend was placed with figure 8 on p. 272. The editors subsequently distributed to book purchasers a corrected legend for this figure.

These criticisms aside, I have high praise for this uniquely important book. It represents a culmination of efforts that started with John Wright's inspiration to organize and carry to fruition the first symposium on *Cnemidophorus*. The book provides superb summaries of evolutionary and ecological research that will prove indispensable for future work on whiptails, as well as especially useful to anyone doing field research on lizards in general. The extensive bibliographies will provide the reader the opportunity to become familiar with the primary literature on virtually any aspect of whiptail biology. I highly recommend the book to those interested in technical work on lizards. At $29, it represents a welcome bargain during times of ever-increasing book prices.

Washington, D.C. 20560, USA.

The Amphibians and Reptiles of Alberta, by Anthony P. Russell and Aaron M. Bauer. 1993. Copublished by The University of Calgary Press, 2500 University Drive, N.W., Calgary, Alberta, T2N 1N4 and The University of Alberta Press, Athabasca Hall, Edmonton, Alberta, T6G 2E8, Canada. ISBN 1-895176-20-4, 264 pp. CAN $24.95 paperback, $29.95 hardcover. [Outside Canada prices are in US $.]

How do you build a full length layman's book out of a herpetofauna of only 18 species? The Russell-Bauer solution is to incorporate much more than just a local field guide into their book. *The Amphibians and Reptiles of Alberta* is really a compact general herpetology text, with special focus on the problems of prairie poikilotherms. The subtitle (printed inside, but strangely not on the cover) accurately describes this volume as both a "field guide" and a "primer of boreal herpetology."

The field guide, i.e. the Keys and Species Accounts, is the smaller portion of the book. The greater portion, the primer, is distributed among assorted chapters with titles such as "Characterization of Amphibians and Reptiles," "Zoogeography of the Alberta Herpetofauna," "Coping with the Cold," and "The Challenge of Aridity."

The scope of this book will make it a valuable addition to every high school and college library in Alberta. In the high school setting this book should help raise student interest in herpetology. In this regard, Tony Russell and Aaron Bauer deserve particular praise for including in their Keys and Species Accounts *Ascaphus truei, Chelydra serpentina, Coluber constrictor*, and *Charina bottae*. None of these species is yet reported in Alberta, but all could be there given their known ranges and ecology. By including these yet-to-be-found species in their book, Russell and Bauer challenge their readers to go out and find them. I can't imagine a better stimulus for neophyte herpetologists—in an admittedly herpetologically depauperate place like Alberta—than a chance to be the first to document a species' presence in the province.

To help the neophyte along, the field guide portion of this book is comprehensive, with good descriptions, keys, maps, natural history notes, glossary, etc. The authors include not just adults, but also eggs and larvae in their keys for amphibians. The Bibliography is much larger than in most existing state or provincial field guides. The color photographs by Wayne Lynch are first rate. They are esthetically pleasing and at the same time clearly reveal the features that distinguish the species.

On the negative side, too many of the line drawings are amateurish. All of the people involved in producing this book should—in good Canadian fashion—apologize to each other for the bizarre drawing on page 8, which shows a tadpole with gills growing out of its rump. Then they should agree to correct the drawing immediately, before any more copies of the book are printed.

In a similar vein, I was amused by two overly simplistic survivorship curves used to demonstrate the difference between r– and K–selection (Fig 7.5). The cartoon sketches of a frog (i.e., r–selected) and *Phrynosoma* (i.e., K–selected), incorporated in that figure, lead the reader to assume that "time," on the X-axis, is minimally one generation. However, if that were true, then we are very lucky not to be buried in short-horned lizards!

There are other problems with production. For example, my review copy of the paperback version had pages 119–126 printed twice.

In future editions the glossary should be expanded. Right now it includes only herpetological terms. But if readers need a definition for "tadpole," they probably need one for "taiga." And if "herpetofauna" deserves definition, then surely so does the "hypothalamus."

The couplet #9 in the Key to Larval Amphibians of Alberta has the word "anterior" where it should be "posterior." The correct information, however, is in the Species Accounts.

All of these flaws are minor and can be cleaned up in future editions. Overall, this is an important book that helps direct attention to boreal herpetology. Given the currently high public interest in a possible global decline of amphibians, this book is particularly timely. For if the issue of global decline is going to be rigorously assessed, we need to be especially attentive to shifts in the distribution of herps near the edges of their range. By informing the public of what is and is not known about the distribution of amphibians and reptiles at their northern limits, this book not only serves the people of Alberta but may ultimately help the 18 species of amphibians and reptiles that try to live up there with them.

The Natural History of West Indian Boas, by Peter J. Tolson and Robert W. Henderson. R&A Publishing, Ltd., Taunton, Somerset, England. 125 pp., 72 color photographs. Hardcover US$75.00. ISBN 1-872688-04-7. Available in U.S. from Eric Thiss, Serpent's Tale Books, 464 Excelsior, Minnesota 55331, USA.

The boid fauna of the West Indies is unique and diverse, and includes some of the first species of reptiles to be recognized as endangered. Tolson and Henderson have produced an important and critically needed text on this subject. This book is a comprehensive, authoritative, and exhaustive analysis of these snakes, addressing their natural history, paleoherpetology, conservation status, and phylogeny.

The first section of the book addresses the natural history, geology, and geography of Greater and Lesser Antilles, with an analysis of each island group. The accounts of the geology and natural history of the Islands are interesting and provide an important framework for understanding the natural history of the boid taxa. The various habitats and biotopes are well illustrated by photographs and descriptive text. The chapter on the phylogeny of the boid fauna is thorough and accurate. The original hypotheses of relationship within this group proposed by Tolson have subsequently been corroborated by Kluge. A chapter on the zoogeography of the boid fauna reviews the fossil record and the phylogeny of this group with respect to the plate tectonics of the region. This information facilitates understanding of the modern distribution of these snakes.

The second section is a species account type of review. In addition to the strictly systematic information, the authors include range maps, natural history notes, food habits (both field observations and husbandry information) as well as reproductive husbandry information. Finally, notes on the conservation status of many of the taxa are included.

The third section is a review of the reproductive biology of *Epicrates* and *Tropidophis*, but does not include reproductive behavior of the two *Boa* taxa. This is not an exhaustive review, but includes interesting observations on captive behavior as well as some of Tolson's seminal studies on the relationships between climate and male-male interactions and testosterone levels.

The fourth section addresses the conservation issues of this group. Interestingly, the authors note that historical errors in population assessments led to incorrect assumptions on the relative scarcity of some taxa. The authors also note that the deleterious effect of the mongoose has been exaggerated.

This text is a superb overview of the boid taxa of the West Indies. Additionally, it is an excellent summary of the geology and natural history of this region, making it useful reading for herpetologists interested in other organisms of this region. The breadth and scope of the authors' analysis make this book fascinating and pleasurable reading, and it is a welcome departure from the traditional boiler-plate herpetology texts.

It is unfortunate that the publisher has priced this book at $75.00. It is also unfortunate that the quality of the illustrations is generally substandard. Many of the color photographs appear to have been improperly separated. The layout of the book is faulty; the top and bottom margins are crowded, and there is excessive white space in many areas. A glossary would have been helpful for those unfamiliar with some of the geologic terms.

These criticisms notwithstanding, this is an essential text for the student of herpetological natural history. It is easy and enjoyable reading, and is the definitive text on this subject.

PUBLICATIONS RECEIVED

Australia's Reptiles [Volume 1: Snakes and Monitors] is based on the book of the same title by Wilson and Knowles. This new CD-ROM contains over 260 photographs of Australian monitors and terrestrial snakes; the full text of every species; distribution maps; scientific and common names; and notes on the current status of most species, and more.

Reptiles can be selected for display by scientific name, common name, genus, or family. The CD-ROM also contains a reptile trivia quiz, a glossary of reptile terms, and notes on the treatment of snakebite in Australia. Fascinating video clips are included from many of the Australian reptile parks.

The CD-ROM is designed for herpetologists, schools, libraries, herpetological societies, and naturalists with an MPC standard IBM-type personal computer with CD-ROM drive.

Volume I is available for US$49 plus $3 shipping from Satronics Communications, P.O. Box 52261, Philadelphia, Pennsylvania 19115-7261, USA. Volume II was planned for issue by November 1994 and contains nearly 800 images of skinks, geckos, and dragons.

For additional information, please write or send Internet mail to: mmiller@tjuvm.tju.edu.

Life on the Edge. A Guide to California's Endangered Natural Resources: Wildlife. Edited by Carl G. Thelander (with 200+ contributors). 1994. Biosystems Books, 303 Potrero Street, Santa Cruz, California 95060-2719, USA (tel. 1-800-983-5433). Format 9x12 inches, 550 pages (500+ pages in color), hardcover (also available in softcover). US $75.00. ISBN 0-930588-66-5.

This hefty (ca. 5 lbs.) volume presents 115 individual species accounts for rare and endangered taxa (fish, amphibians, reptiles, birds, mammals, and invertebrates). Species of herps profiled by individual accounts include seven salamanders (*Ambystoma macrodactylum croceum, Plethodon stormi, Batrachoseps aridus, B. simatus, B. stebbinsi, Hydromantes shastae*, and *H. brunus*), one anuran (*Bufo exsul*), the desert tortoise (*Gopherus agassizii*), four lizards (*Coleonyx switaki, Uma inornata, Gambelia sila*, and *Xantusia riversiana*), and four snakes (*Charina bottae umbratica, Masticophis lateralis euryxanthus, Thamnophis sirtalis tetrataenia*, and *T. gigas*). Interviews with prominent conservationists (such as Robert Stebbins and Kenneth Norris) and essays are included. The connections of Native American legends to wildlife are examined and illustrated. Although herpetologists are not likely to find much new information about their favorite animals here, this is a visually impressive volume that effectively conveys the magnitude of conservation problems facing Californians and their wildlife.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Techniques, Natural History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles or Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editor only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided at the time page proofs are sent to the authors. Proofs are not sent to authors of Natural History Notes or Geographic Distribution manuscripts; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, New Jersey Field Office, The Nature Conservancy, 200 Pottersville Road, Chester, New Jersey 07930, USA (tel. 908-439-3007).

Herpetological Review is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Karen Toepfer, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 580		$290
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 580	$130

For back orders only: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA (fax 314-977-3117).

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees. All members receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

ANNUAL DUES AND SUBSCRIPTIONS–1995: The fees for individual memberships and institutional subscriptions are as follows: Individual membership US$40; Student membership $25; Family membership $55; Institutional subscription $70; Additional fee for air mail postage outside USA $25. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $15; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Karen L. Toepfer, SSAR Treasurer, P.O. Box 626, Hays, Kansas 67601–0626, USA. Telephone: (913) 623-4258; Fax: (913) 625-8890; e-mail: aren@ksuvm.ksu.edu or aren@ksuvm.bitnet.

Future Annual Meetings

1995 — Appalachian State University, Boone, North Carolina, USA, 8–13 August (R. Wayne Van Devender, Chair).
1996 — University of Kansas, Lawrence, Kansas, USA, 24–29 July (William E. Duellman, Chair).
1997 — University of Washington, Seattle, Washington, USA, 25 June–2 July.

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (to serve as President for 1996): *Louis J. Guillette, Jr.*

Secretary: *J. Eric Juterbock* (unopposed).

Treasurer: *Karen L. Toepfer* (unopposed).

Directors: *Don C. Forester, Lyndon A. Mitchell.*

Symposium on Amphibian Development

At the annual meeting in Boone, North Carolina (8–13 August 1995), SSAR is sponsoring a symposium on "Evolutionary Patterns of Amphibian Development," organized by Stephen Deban (University of California at Berkeley). This symposium features topics of amphibian development that are viewed from a comparative perspective. The focus is on how developmental mechanisms may contribute to evolutionary changes in amphibian lineages. Topics feature the effects of genome size on development, how physiological mechanisms may affect the evolution of metamorphic and paedomorphic forms, and overviews of the evolution and development of morphology and behavior in salamanders. The half-day symposium features the work of senior graduate students and recent post-doctoral students.

About our Cover

Trimeresurus flavomaculatus is a pitviper species endemic to the humid pluvial forests of the Philippines, an archipelago of about 7100 islands lying approximately 800 km off the SE coast of Asia. It is widespread and may include more than one species, although biochemical analyses will be necessary to establish this. As recognized presently, this species exists in a broad array of patterns and colors as well as feeding and microhabitat preferences: some are terrestrial, others arboreal. The most recent studies have been conducted by Leviton (1964. Philippine J. Sci. 93(2):251–276), and Schätti and Guillod (1990. Herpetofauna 12(66):32–34). The snake on the cover is a female, approximately 1400 mm in total length, from the live collection of The University of Texas at Arlington Collection of Vertebrates. It was photographed with a Pentax LX camera, Vivitar 90 mm f2.5 macro lens, on Fujichrome Velvia film, at 1/75th of a second at f22. The photographer is herpetologist William W. Lamar, Adjunct Professor at The University of Texas at Tyler and Research Associate at UT Arlington. He is co-author (with Jonathan A. Campbell) of *The Venomous Reptiles of Latin America*. When not conducting research on herps, Bill leads herp- and wildlife-oriented tours for Green Tracks, Inc.

SSAR Student Travel Awards Call for Applications

Ten SSAR Student Travel Awards of $200 each are available to undergraduate and graduate student members of the SSAR to help defray the cost of travel to the upcoming meeting in Boone, North Carolina. An applicant must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author of a paper or poster to be presented. An applicant must include in the application package:

1) a letter signed by his or her major advisor or department chair stating that he or she is currently an undergraduate or graduate student and that he or she is not completely funded for travel from another source;

2) an official copy of the poster or paper abstract to be presented;

3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Travel Awards Committee are excluded from applying for a travel award. APPLICATIONS MUST BE POSTMARKED BY 15 MAY 1995. Award recipients will be notified by early June 1995 and award checks will be dispersed at the meeting. Send applications to: *Dawn S. Wilson, Department of Biology, University of South Florida, Tampa, Florida 33620, USA. For further information Wilson may be contacted at: Tel. (813) 974-9175, FAX (813) 974-3263; e-mail WILSON@CHUMA.CAS.USF.EDU.*

SSAR Student Travel Awards Fundraiser Call For Donations

At the 1994 SSAR/HL meetings in Athens, Georgia, the newly formed SSAR Student Travel Awards Committee organized a frameable art silent auction to raise funds for students attending and presenting papers at an annual meeting. Because of the great success of the first silent auction (over $2000 raised), the Travel Awards Committee is pleased to announce the second frameable art silent auction to be held at the 1995 SSAR meeting in Boone, North Carolina. Many people attending the Athens meeting expressed an interest in donating an item to the silent auction. Items acceptable as a donation include: photos of your favorite study animal (or herpetologist!), line drawings, prints, paintings, or anything else that can be put into a frame, if not framed already. If you are interested in donating an item please contact Dawn S. Wilson (contact numbers above).

Herpetological Review Now On-line

A pre-publication listing of the contents of each issue of *HR* is now available from several on-line sources. Postings should occur approximately one month before the publication of the next issue. This service should be helpful to herpetologists in countries where mail delivery is unpredictable, as well as providing pre-publication information to other interested persons. *HR*'s on-line contents listing is available from the following:

Society for the Study of Amphibians and Reptiles
1995 Annual Meeting

Dates: 8–13 August 1995
Place: Appalachian State University, Boone, North Carolina, USA

Keynote Address: "Territorial Behavior: Testing the Assumptions," by Judy Stamps (University of California, Davis).

Symposium: "Eastern Rattlesnakes: Biology and Conservation of *Crotalus horridus* and *Crotalus adamanteus*." *Organizers*: William S. Brown (Skidmore College, Saratoga Springs, New York, USA) and Walt Timmerman (Helena, Montana, USA). *Participants for session on Timber Rattlesnake*: W. S. Brown, B. W. Bowen, A. -M.Clark, L. M. Bushar, H. K. Reinert, D. E. Keyler, B. L. Oldfield, R. Stechert, A. Breisch, S. H. Harwig, S. Smith, W. H. Martin, E. Possardt, T. Tyning, R. T. Zappalorti, D. Wynn, A. H. Savitzky, B. A. Savitzky, G. Rocco, J. B. Sealy, A. Soha, J. T. Taylor, A. C. Smith, Jr., K. Michell, R. R. Rupert, Jr., D. F. Fraser, J. Congdon. *Participants for session on Eastern Diamondback Rattlesnake*: W. Timmerman, W. Auffenberg, W. H. Martin, D. B. Means, G. Dalrymple, P. Kain, S. Telford, J. W. Gibbons, R. Mount, L. Jones.

Symposium: "Evolutionary Patterns of Amphibian Development." *Organizer:* Stephen M. Deban (University of California, Berkeley, USA). *Participants*: S. M. Deban, J. C. O'Reilly, D. M. Parichy, S. B. Marks, C. S. Rose, E. L. Jockusch.

Regional Societies Conference: "Regional Herpetological Societies: Programs and Projects." *Organizer*: Martin J. Rosenberg. Participants not yet finalized.

Workshop: "Herp Photography." *Organizers*: David Dennis and J. Eric Juterbock.

President's Travelogue Slide Shows: Profusely-illustrated lectures of exotic herps and habitats.

Multimedia Presentations: "Herps of the West" and "Amphibians of the Appalachians" by David Dennis and J. Eric Juterbock; "Herpetological Namesakes" by Kraig Adler, David Dennis, and J. Eric Juterbock.

Oral and Poster Sessions: Several concurrent sessions each day.

Student Paper Awards: Seibert Prizes to be awarded to the two best student-presented papers at the meeting ($250 first prize, $150 second prize).

Student Travel Grants: Ten awards of $200 each will be given. For details see SSAR Business in this issue (p. 1).

"The Great Reprint Scavenge" (for students only!). Professionals are asked to clear unwanted duplicate reprints out of their offices (and receive free raffle tickets as a "thank you").

Social Activities: Welcoming Social, the SSAR Annual Auction, Barbecue Dinner, Graduate Student Social, local tours.

Field Trips: Grandfather Mountain, Linville Gorge Wilderness Area, night trips for salamander watching, and others.

Live Exhibit: Featuring herps of the region. Sponsored by the North Carolina Herpetological Society and Appalachian State University. Animals available for viewing and photography.

Costs and Accommodations: Registration $75 student, $110 regular; $50 spouse. After 15 April 1995, registration fees will be $115, $145, and $50, respectively. Lodging at Broyhill Inn (meeting location) will be $40 (single occupancy) or $46 (double occupancy) per day. Dormitory room rates are $15 (single) or $10 (double) per day plus $8 for linen. Approximately 100 additional rooms are reserved at several local motels for $49–$70 per day. Note that Boone, North Carolina is a popular summer resort area; reservations should be made well in advance.

Further Details: See December 1994 issue of *Herpetological Review* (pages 133–135). Meeting Announcement/Call for Papers was mailed to all North American members of SSAR in January 1995; it is also available on request from *Dr. Robert Wayne Van Devender, Department of Biology, Appalachian State University, Boone, North Carolina 28608, USA (telephone 704-262-2665; fax 704-262-2127; e-mail vandevenderr@appstate.edu).* Address questions about meeting sites, rooms, registration, etc., to *Richard Hudson, Office of Conferences and Institutes, University Hall (telephone 704-262-3045; fax 704-262-4992; e-mail hudsonre@appstate.edu).*

SPECIAL OFFER TO ALL STUDENT HERPETOLOGISTS!

Free Copy of "Turtles of Venezuela" for Students Attending the August Meeting

AS AN INCENTIVE TO JOIN THE SOCIETY AND TO ATTEND its August meeting, SSAR is making a special offer. All student SSAR members who register for and attend the August 8–13, 1995 meeting in Boone, North Carolina, will receive a free copy of Pritchard and Trebbau's classic, "The Turtles of Venezuela," published by SSAR in 1984. The list price is US$45. This 414-page, clothbound book contains 48 color plates (25 watercolor portraits and 165 photos of turtles and habitats), with keys and spot distribution maps. This book is an exhaustive biology and natural history of the turtles of northern South America and covers fully half of the turtle species on the continent.

Dr. Peter Pritchard will be in attendance at the meeting and has kindly agreed to autograph copies on request.

In order to take advantage of this one-time-only offer, you must already be a student member of SSAR or join before the Boone meeting. The special student membership rate is still only US$25, which entitles you to receive *Journal of Herpetology* and *Herpetological Review* (4 issues of each per year) plus get pre-publication discounts on other SSAR publications. If you wish to join, fill out the spaces below.

YOUR NAME: _____

ADDRESS: _____

_____

POSTAL CODE: _____ COUNTRY: _____

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Send this form, or a copy of it, with payment, to:

Karen L. Toepfer, SSAR Treasurer
PO Box 626, Hays, Kansas 67601–0626, USA.

Telephone: area code 913, 623–4258.
Fax: area code 913, 625–8890.

When you register for the meeting, please mark the student box and indicate that you want a copy of "Turtles of Venezuela," so that we can have the proper number of copies shipped to North Carolina for distribution. *The deadline for requesting the book is 1 July 1995.*

Herp-Net — direct dial to 215-464-3562 (300-2400bps 8-N-1) or 215-698-1905 (9600, 14.4kbs) 24 hours per day. Select "Herp. Review" menu item.

Via **Usenet** newsgroup, "sci.bio.herp" (use any newsreader available on your network account), look for the posting "Herpetological Review Contents."

Via the **HERP-L** distribution list available to any Internet address. To subscribe send email to listproc@xtal200.harvard.edu with the phrase "subscribe HERP-L <your name>" in the body of the message.

On the commercial **CompuServe** Information Service in their Animal Forum (Go Petstwo) reptile/amphibian library section 6. Search by keyword "SSAR."

This service is made possible by Mark Miller and the Herpetology On-Line Network. Miller can be reached by FAX at 215-464-3561 or Internet email: mmiller@tjuvm.tju.edu.

SSAR General Guidelines for Field and Laboratory Studies on Amphibians and Reptiles

These guidelines were endorsed during the 1994 meeting of the SSAR Board of Directors. The intent of the guidelines is to focus the attention of herpetologists on ethical issues that are a part of the research process. Consideration of these issues, as reflected in the guidelines, should enhance the quality of herpetological research and minimize the impact of research on populations of amphibians and reptiles, and on their habitats.

I. Collecting

A. Investigators should consider the impact of collecting on a population, and remove no more individuals than necessary. Alternative non-lethal means of sampling should be considered.

B. Investigators should obtain the appropriate collecting and land-use permits.

II. Field Observations and Experiments

A. Investigators should attempt to minimize disturbance to the habitat, and to target and non-target populations.

B. Investigators should conduct appropriate preliminary studies to determine whether observation, confinement, or experimental manipulation affect the behavior of target animals.

C. Investigators should remove all markers, equipment, supplies, etc. from their field sites at the end of their project.

III. Laboratory Observations and Experiments

A. Animals should be obtained only from legal sources.

B. Given normal logistic and hygienic constraints, maintenance housing should simulate natural conditions of temperature, light, moisture, shelter, and cleanliness, and should follow appropriate animal care guidelines.

C. If animals are killed during or as a result of experimentation, or are subjected to pain or stress, the investigator should consider whether alternative experiments are possible, or whether the experiment should be performed at all.

D. The investigator should consider experimental designs by which sample sizes can be reduced or should perform experiments that collect several kinds of data on the same individual.

IV. General

A. Investigators should acquaint themselves with special rules of conduct or policies applicable to the area or habitat visited.

B. Investigators should abide by the spirit as well as the letter of relevant legislation.

NEWSNOTES

Hamadryad

Currently in its 19th volume, *Hamadryad* is Asia's oldest peer-reviewed herpetological journal, and is published by the Centre for Herpetology, Madras Crocodile Bank Trust, India.

Recent papers in *Hamadryad*: Checklist of the amphibians of India; Territory-marking in *Eublepharis macularius*; Distribution of *Varanus salvator* in the Philippines; Breeding biology of *Aspideretes nigricans* in Chittagong; Eggs and hatchlings of lizards from Borneo; Captive breeding of frogs; Biology and conservation of wart snakes; Social hierarchy in *Varanus salvator*; Natural history of *Kachuga smithii*; Distribution of *Gavialis gangeticus*; Snake conservation in Sri Lanka; New species of *Cnemaspis* gecko from Indonesia; Sex ratios of Indian freshwater turtles; Feeding ecology of *Lissemys punctata*; Herpetology of Lambir Hills, Sarawak; Checklist of Pakistani geckos; New locality records of *Kachuga sylhetensis*; Growth of *Eretmochelys imbricata*; *Ophiophagus hannah* from a marginal habitat; Man-eating by *Crocodylus palustris*.

Annual subscription is US$25.00 (inclusive of airmail postage for one volume). Checks should be made out to "Madras Crocodile Bank Trust" and sent to: *Centre for Herpetology, Madras Crocodile Bank Trust, P.O. Bag 4, Mamallapuram, Tamil Nadu 603 104, India.*

New Journal from Sri Lanka

The Amphibian and Reptile Research Organization of Sri Lanka (ARROS) announces the publication of *Lyriocephalus*. This is the only journal dedicated to the publication of papers concerning the taxonomy, ecology, conservation, and other aspects of amphibians and reptiles of Sri Lanka. Each edition will include articles, short communications, book reviews, and announcements of activities and research projects of ARROS. Two issues per year are planned.

The contents of Volume 1, Number 1 are: An introduction to the herpetofauna of Sri Lanka; The Amphibia of Sri Lanka: a provisional checklist and their common names; The *Ichthyophis* in Sri Lanka: a short review; Natural history of *Ramanella obscura* (Amphibia: Microhylidae): some preliminary observations; Some notes on *Gonydactylus frenatus* (Gunther, 1864) (Reptilia: Gekkonidae); Amphibians and reptiles observed at Galekanda, Panwilathane; Some vernacular names of terrapins in Sri Lanka; Snakes observed in Gampola, Sri Lanka; Pattern of snakebite in Kandy District; *Amphiesma stolata* (Linnaeus, 1758): additional Sinhala names; Some beliefs regarding chelonians in Sri Lanka; Preliminary report of snakes and agamid lizards in Galle district; Some popular beliefs, traditions and practices concerning amphibians and reptiles of Sri Lanka; Reptile fauna of the Knuckles Range: Sri Lanka; Some reptiles and amphibians observed at Mahaweli System B and C; and two book reviews. The editor is Bryan Walker. The editorial board consists of W. R. Breckenridge, Indraneil Das, D. G. A. Perera, and Anslem de Silva.

Lyriocephalus is available for US$10.00. ARROS can cash personal checks, but cash is preferred because of the high cost of exchange. Orders should be sent to: *Anslem de Silva, President, ARROS, c/o Faculty of Medicine, University of Peradeniya, Peradeniya, Sri Lanka.*

Sociedad Herpetológica Mexicana

The Sociedad Herpetológica Mexicana invites all interested herpetologists to participate as members of the society. All members receive the publication *Boletín de la Sociedad Herpetológica Mexicana*, published two times per year. A national meeting is held every two years. The annual fees for individual membership are US$25.00 and US$15.00 for students. Payment should be made to Sociedad Herpetológica Mexicana and sent to: *Amaya González, ENEP-Iztacala, Laboratorio de Herpetología, Ap. Postal 314, 54090 Tlalnepantla, Edo. de México, México.*

Southwestern Research Station Volunteer Positions for 1995

Approximately 20 volunteer positions are open in 1995 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. 602-558-2396.*

Biology of Plethodontid Salamanders

A summer course of the same title will be offered 5–16 June 1995 at the Highlands Biological Station, located in the Blue Ridge Mountains of North Carolina—a region renowned for the diversity of its salamander fauna. The course will be taught by Dr. Stephen G. Tilley (Smith College) and is designed to acquaint students with plethodontid salamanders and to show how studies of these animals have enhanced our understanding of a series of major evolutionary and ecological topics. Numerous trips to significant salamander localities are a highlight of the course. For information, contact: *Highlands Biological Station, P.O. Drawer 580, Highlands, North Carolina 28741, USA. Tel. (704) 526-2602.*

MEETINGS

Meetings Calendar for 1995

22 April 1995—18th Annual All Florida Herpetological Conference. University of Florida, USA. Contact: Dr. David L. Auth (tel. 904-392-1721). *See further information below.*

2–6 June 1995—10th Annual Meeting of the Society for the Preservation of Natural History Collections (SPNHC). Royal Ontario Museum, Toronto, Canada. SPNHC '95 *Preserving the Record of Nature through Countless Ages*. Contact: Janet Waddington, Royal Ontario Museum, 100 Queen's Park, Toronto, Ontario, Canada M5S 2C6.

15-19 June 1995—Annual Meeting of the American Society of Ichthyologists and Herpetologists and The Herpetologists' League. University of Alberta, Edmonton, Alberta, Canada. Contact Dr. Joseph S. Nelson, Department of Biological Sciences, University of Alberta, Edmonton, Alberta, Canada T6G 2E9. Tel. (403) 492-4741. FAX (403) 492-9234. E-mail: joe_nelson@biology.ualberta.ca.

23–25 June 1995—International Gecko Society Symposium. Palm Mountain Resort, Palm Springs, California. Contact IGS Symposium, P.O. Box 370423, San Diego, California 92137-0423, USA. *See ad on page 40 for further details.*

6–10 July 1995—International Congress of Chelonian Conservation. Tortoise Village, Gonfaron, France. Contact: Secretariat, SOPTOM, B.p. 24, 83590 Gonfaron, France. Tel. (33) 94 78 26 41. Fax (33) 94 78 24 27.

8–13 August 1995—Annual Meeting of the Society for the Study of Amphibians and Reptiles. Appalachian State University, Boone, North Carolina, USA. *Refer to meeting announcement on page 2 of this issue for contact numbers and other information.*

6–10 September 1995—2nd International Asian Herpetological Meeting. Ashgabat, Turkmenistan. Contact: Theodore J. Papenfuss, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA. Tel. (510) 642-3567. Fax (510) 643-8238. E-mail: asiaherp@uclink2.berkeley.edu.

18th Annual All Florida Herpetology Conference

The All Florida Herpetology Conference will be held 22 April 1995 at the University of Florida in Gainesville. The Florida Museum of Natural History and Gainesville Herpetological Society co-sponsor the event. Walter Auffenberg, David Auth, David Barker, Greg Brock, James Cox, Dante Fenolio, Robert Herrington, Harvey Lillywhite, Peter May, Joseph Mitchell, Ray Pauley, Michael Ready, and Kevin Wright will give talks. Richard Funk and Mark Wilson will conduct disease prevention workshops, and Patricia Ashton will lead a Young Herpetologists' Workshop. Herpetological art, supplies, and books will be exhibited for sale. An evening barbecue and auction will be held at the museum. To preregister, call or write to *Dr. David L. Auth, Division of Herpetology, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA. Tel. (904) 392-1721.*

LETTERS TO THE EDITOR

Is the SSAR an American or an International Society?

According to statistics released by the SSAR in 1983 and 1991, one out of five SSAR members resides outside the USA. Indeed, unlike other herpetological societies in the USA and the world, the SSAR's name includes no geographical specification. Nevertheless, all of the 38 key functionaries listed on the inside covers of Herpetol. Rev. 25(2), have US addresses; none of those hundreds of foreigners serves. This is remarkable because, most probably, those herpetologists, in any country, who elect to pay membership in a society abroad and to subscribe to a journal in a foreign language (how many Americans do so?) stand above the average of national society members.

Initially one tends to explain this deficiency, on the one hand, as a natural outcome of democratic election processes, and on the other hand, as practical for functional purposes. However, doubt as to the completeness of these explanations is raised by a statement in Herpetol. Rev. 25(2):41. Under "Donations Needed for SSAR Symposium," we read, "All donations are tax-deductible..." The item is not signed, so the Editor is responsible. Hence I ask: in how many countries other than the USA, of the tens in which members live, was this verified before printing the announcement? If, as I suspect, the answer is "none" (or "only Canada"), I ask further: are the non-USA members considered by the Editor as negligible, or have they merely been ignored?

YEHUDAH L. WERNER
Department of Evolution, Systematics and Ecology
Hebrew University
91904 Jerusalem
Israel.

The Editor replies.— Professor Werner is correct: we erred in not stating that income-tax deductibility would apply only to US members. As an international society based in the USA, SSAR has had a longstanding policy to avoid use of words such as "foreign," "foreigner," or any others that imply differential treatment of US and non-US members, but occasionally we slip up. Our policy also extends to the subtle addition of "USA" to the addresses of US officers and authors in all SSAR publications.

SSAR has as active international program. All of its publications are international in scope and its books in recent years have concerned Arabia, Australia, Brazil, China, Costa Rica, Iran, and Venezuela, and it is now becoming the major publisher of herpetological books on Asia. Several of these have been issued jointly with overseas herpetological societies. SSAR has actively supported international herpetological activities, most notably by making sizable grants to the first two world congresses. It also makes research grants to students from throughout the world. The society's own meetings are sometimes held outside the USA (in México and the UK, with plans for a Canadian meeting). We regularly have many overseas members at our meetings in the USA and special efforts are made to make them feel welcome. Prof. Werner himself has participated in these meetings on several occasions.

There is a practical restriction, however, on the national composition of the SSAR Board of Directors. Although any members may be elected, regardless of nationality, in order for the Board to function its members must meet together, face-to-face, at least once a year. Nominees must commit themselves to attend all Board meetings during their three-year term and, as most meetings are in the USA, this puts an additional burden on non-US members. Beginning in 1982, SSAR has designated one Board seat for someone outside the USA, which to date has been held by persons from Canada, México, and the UK. Our various committees and editorial boards, which originate many of the operating procedures and supervise the programs of SSAR, traditionally have international memberships. Moreover, by my count, 24% (176 of 726) of the authors of articles and notes appearing in the *Journal of Herpetology* and *Herpetological Review* for 1994 had non-USA addresses; this approximates the percentage (21%) of SSAR members who reside outside the USA.

It should also be noted that all members in SSAR are entitled to vote, whereas in some other societies only those in attendance at meetings do so, thus in effect restricting elections to US members. In short, SSAR has for a very long time encouraged international participation in developing and carrying out its programs. It is constantly seeking new ways to do so, however, and solicits members' ideas and advice. Please address your letters to the SSAR President for 1995: *Dr. Alan H. Savitzky (Department of Biological Science, Old Dominion University, Norfolk, Virginia 23508, USA. E-mail AHS100F@ODUVM.CC.ODU.EDU; FAX 804-683-5283).*

More on Conservation Biology

Campbell and Frost (1994. Herpetol. Rev. 25:100–102) describe vividly the problem of biological regulation. Biologists have complained privately for a generation; in public they've generally asked for what they got—motivated by an obviously false moral assumption (Porter 1993. Bull. Chicago Herp. Soc. 28:154–155)—and they're still asking today.

I suggest Campbell and Frost didn't go far enough. Biologists are indeed slow learners when it comes to political realities. They hope for special privilege: to just regulate others and leave themselves alone. That's no solution because the problem is more general. Political reality means putting public appearance over genuine reality. That means hype over substance and sound-bite over strategy; the treatment accorded systematists is a fitting model for any projected means to a long-term goal which comes under such short-range jurisdiction.

That's why political protection generally doesn't work. Herpetoculture does, because its animals are protected, *genuinely* protected, against all the rest of mankind—regardless of power, pull, or influence—by the private property system. That's the best possible protection against the depredations of men. Then the ideal solution, rarely feasible, is for private individuals (or groups) who do appreciate *Abronia*, etc., to privately buy, own, and manage appropriate habitat. Hindering this is where political regulation does the worst damage.

TOM PORTER

Reseda, California 91335, USA.

CURRENT RESEARCH

With this issue we introduce a new section to *HR*. The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editor: Breck Bartholomew, 195 West 200 North, Logan, Utah 84321-3905, USA. Comments and suggestions are also welcome.

Temperature-dependent Sex Determination

Richard C. Vogt discusses the possibility of using temperature-dependent sex determination (TSD) as a conservation tool in a recent issue of *Chelonian Conservation and Biology*. He argues that conservation programs that artificially incubate turtle eggs should attempt to produce more females than males, since male turtles breed with more than one female. This departure from the desired 1:1 sex ratio may help turtles recover faster. If, however, Frederic J. Janzen's predictions, based on a population of *Chrysemys picta* on an island in the Mississippi River are realized, global warming will cause many turtle species to produce primarily females.

VOGT, R. C. 1994. Temperature controlled sex determination as a tool for turtle conservation. Chelonian Conserv. Biol. 1(2):159–162.

JANZEN, F. J. 1994. Climate change and temperature-dependent sex determination in reptiles. Proc. Natl. Acad. Sci., USA 91:7487–7490.

Several additional papers on TSD in reptiles were published in the *Journal of Experimental Zoology*..Contents of this issue are:

LANCE, V. A. 1994. Introduction: Environmental sex determination in reptiles: Patterns and processes. J. Exp. Zool. 270(1):1–2.

EWERT, M. A., D. R. JACKSON, AND C. E. NELSON. 1994. Patterns of temperature-dependent sex determination in turtles. J. Exp. Zool. 270(1):3–15.

MROSOVSKY, N. 1994. Sex ratios of sea turtles. J. Exp. Zool. 270(1):16–27.

Amphibian Water Economy

C. Barker Jørgensen recently published the results of experiments on water balance and hydration behavior in toads only to find similar experiments had been conducted nearly 200 years ago by Robert Townson. Jørgensen found these eighteenth century experiments to be of such importance he decided to revive Townson's work and incorporate it into modern literature.

JØRGENSEN, C. B. 1994. Robert Townson's observations on amphibian water economy revived. Comp. Biochem. Physiol. 109A(2):325–334.

Duvernoy's Secretions

Scott A. Weinstein and Kenneth V. Kardong reviewed the properties of Duvernoy's secretions in a recent paper published in *Toxicon*. In addition to reviewing the protein content and toxicity of these secretions, they also reviewed methods of secretion extraction, storage, and assay.

WEINSTEIN, S. A., AND K. V. KARDONG. 1994. Properties of Duvernoy's secretions from opisthoglyphous and aglyphous colubrid snakes. Toxicon 32(10):1161–1185.

Jaw Musculature

The premier issue of the *Russian Journal of Herpetology* includes a paper by Iordansky on the tendinous jaw muscles of several amphibians and reptiles. Homology and evolution of jaw musculature is discussed within both the Amphibia and Reptilia.

IORDANSKY, N. N. 1994. Tendons of jaw muscles in Amphibia and Reptilia: Homology and evolution. Russian J. Herpetol. 1(1):13–20.

The Linnean Society recently published a study of the jaw adductor musculature of alethinophidian snakes. In addition to proposing new nomenclature for the jaw adductor musculature in snakes, Hussam Zaher discusses phylogenetic relationships based on this musculature. Phylogenetic conclusions include support for Acrochordidae + Colubridae monophyly, separating the Tropidophiidae from all other Caenophidia, and removing Xenopeltidae from the 'booids.' In another recent paper Zaher uses this musculature data as well as additional morphological data to show the Tropidopheoidea *sensu lato* is polyphyletic. In order to make the taxonomy reflect recovered history Zaher recommends placing *Ungaliophis* and *Exiliboa* within the Booidea as a family, Ungaliopheidae. *Tropidophis* and *Trachyboa* remain in the superfamily Tropidopheoidea. This second paper is in French with an English abstract and two-page abridged version.

Amphibian Decline?

Although a number of recent papers have addressed aspects of amphibian decline, one is particularly interesting because it duplicates a survey completed by Frank Blanchard in 1923. During 1991 and 1992 Michael J. Lanno and colleagues surveyed the wetlands of Dickinson County, Iowa for amphibians. They found seven species of amphibians, five of which were recorded by Blanchard's survey. One of the new species, *Rana catesbeiana*, was introduced by state fisheries biologists while the other new species, *Bufo cognatus*, is thought to have migrated into the area. Two species reported by Blanchard were not found during Lanno et al.'s survey.

LANNO, M. J., K. LANG, T. WALTZ, AND G. S. PHILLIPS. 1994. An altered amphibian assemblage: Dickinson County, Iowa, 70 years after Frank Blanchard's survey. Am. Midl. Nat. 131:311–319.

Biomechanics

Bipedal locomotion is common in several species of tetrapodal reptiles and is commonly used during quick acceleration. Christian et al. present biomechanical arguments to show how and why bipedalism facilitates quick running.

CHRISTIAN, A., H.-G. HORN, AND H. PREUSCHOFT. 1994. Biomechanical reasons for bipedalism in reptiles. Amphibia-Reptilia 15(3):275–284.

Molecular Techniques

The hypothesis that multiple matings result in multiple paternity in *Vipera berus* was tested by Tegelström and Höggren trough the use of DNA fingerprinting and random amplified polymorphic DNA (RAPD). DNA fingerprinting proved most effective for distinguishing between large numbers of putative fathers, but both methods were adequate when fewer potential fathers were involved.

TEGELSTRÖM, HÅKAN, AND MATS HOGGREN. 1994. Paternity determination in the adder (*Vipera berus*)–DNA fingerprinting or random amplified polymorphic DNA. Biochemical Genetics 32(7/8):249–256.

Roger S. Thorpe and colleagues utilized several mtDNA regions as well as nuclear DNA to determine the colonization sequence of the Canary Island lizard *Gallotia galloti*. Although the nuclear DNA RAPD analysis and the 12s rRNA were unable to resolve the closer relationships, the other four methods yielded virtually identical phylogenies. A biogeographic hypothesis derived from the combined molecular data was consistent with the geologic history of the islands.

THORPE, R. S., D. P. MCGREGOR, A. M. CUMMING, AND W. C. JORDAN. 1994. DNA evolution and colonization sequence of island lizards in relation to geological history: mtDNA RFLP, cytochrome b, cytochrome oxidase, 12s rRNA sequence, and nuclear RAPD analysis. Evolution 48(2):230–240.

Lizard Ecology

Habitat, microhabitat, diel activity, and prey taxa and size were analyzed for five of the twelve species of lizards occurring at El Pinacate, Sonora, México. Unfortunately the publisher has apparently decided to print the tables and figures cited in this paper in part II which is expected in the December 1994 issue. Once these data are included this paper should be an important ecological study for this area.

ORTEGA-RUBIO, A., A. GONZALEZ-ROMERO, AND R. BARBAULT. 1994. Structure and functioning of a desert lizard community at El Pinacate, Sonora, Mexico. Part 1. The Herptile 19(3):120–128.

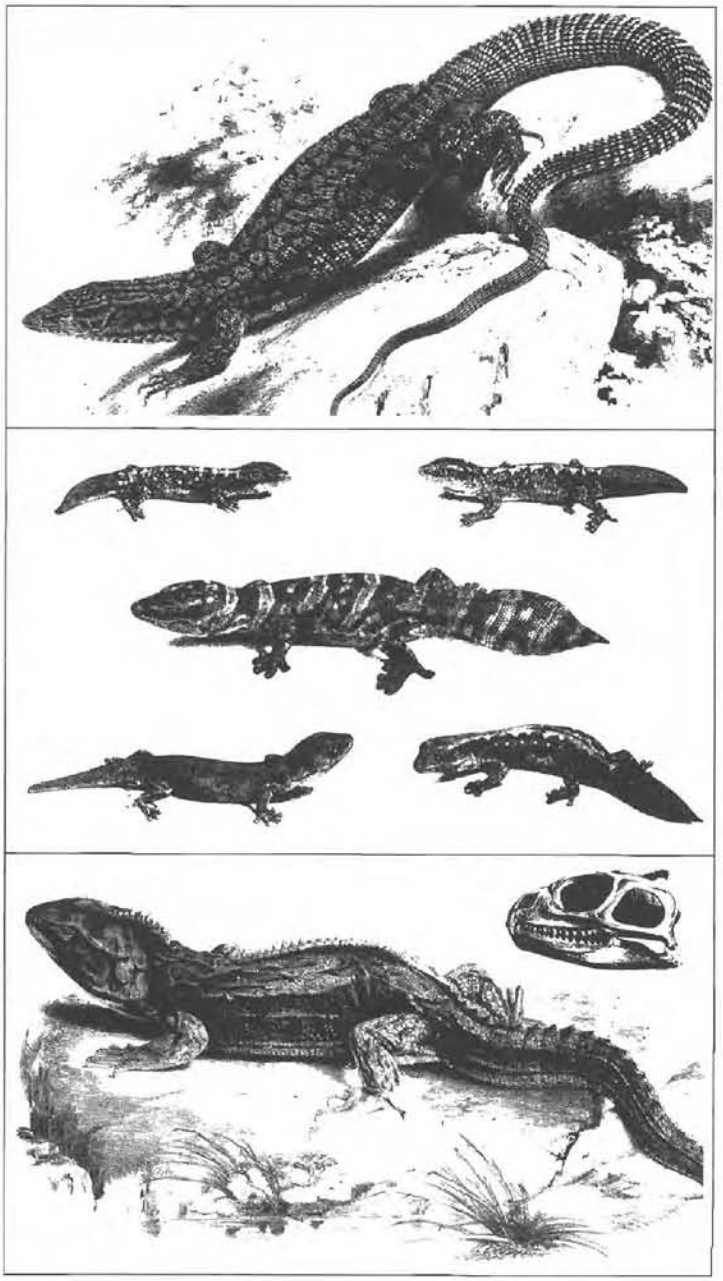
ARTICLES

A Review of the Adaptive Strategy Used by Hatchling Painted Turtles to Survive in the Cold

Painted turtles (*Chrysemys picta:* family Emydidae) are common residents of shallow lakes, ponds, and marshes across much of North America. They occur in southern Canada from Nova Scotia to British Columbia, and east of the Rocky Mountains in the U.S.A. as far south as Georgia, Alabama, Mississippi, and Louisiana (Ernst and Barbour 1972). These are among the best-studied of all freshwater turtles, owing to their extensive distribution, local abundance, diurnal habits, and ease of capture.

Courtship and mating occur among painted turtles soon after they emerge from winter dormancy, and nesting occurs a few weeks

A New Facsimile Reprint from the Society for the Study of Amphibians and Reptiles



THE LIZARDS OF AUSTRALIA AND NEW ZEALAND

by John E. Gray and Albert Günther

with an introduction by Glenn M. Shea (University of Sydney)

THIS BOOK represents the first monograph dealing exclusively with the herpetofauna of Australia and New Zealand. It consists of two separate but related works that share the same set of plates. The first of these, by Gray and Günther, was issued in two sections (1845, 1875), as part of the scientific results of the voyage of H.M.S. *Erebus* and *Terror*, commanded by Captain Sir James Ross Clark, and sent by the British Admiralty during 1839–1843 to determine the limits of Antarctica and to explore Australia and New Zealand. This is the first comprehensive review of the lizards of Australia and New Zealand and gives the scientific name, synonymy, description, and distribution of each species. Many new species are described for the first time. The second work being reprinted in this volume is Gray's monograph, "The Lizards of Australia and New Zealand in the Collection of the British Museum" (1867), which is also a checklist containing the basic details for each species.

The outstanding feature of this reprint are the 20 lithographic plates, drawn by G. H. Ford, staff artist at the British Museum and one of the best natural history artists of the 19th century. These plates illustrate monitors (4 plates), pygopodids (1), geckos (3), skinks (9), agamids (2), and one of the tuatara, which was then classified as an agamid lizard. These exquisite drawings are among the most detailed and lifelike ever produced on the Australian and New Zealand herpetofaunas. They represent the first published illustrations of many of these species, including the tuatara. Half of the plates illustrate single animals in natural poses, whereas each of the others have as many as 15 figures (see reproductions, greatly reduced in size, at right).

Because these plates are of such exceptional quality, complete sets are being made available separately, printed on one side only of a heavy, acid-free paper stock. These plates measure 8 $^1/_2$ × 11 inches and are suitable for framing.

Specifications: 80 pages, 20 full-size plates. Format 8 $^1/_2$ × 11 inches (21.5 × 28 cm). Clothbound. To be published June 1995. ISBN 0–916984–34–6.

- Price of book to Institutions and Non-members . . . . . $ 20
- Price of set of 20 plates, in protective plastic wrapper . $ 12

Shipping: In USA, add $2 per copy; non-US, add $4.

Send orders to Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103, USA (*Telephone*: area code 314, 977–3910 or –3916; *fax*: 314, 977–3117). Please make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks (include an additional amount to cover bank conversion charges) or by International Money Order. Orders may be charged to MasterCard or VISA (account number and expiration date must be provided). Membership details and a complete list of SSAR publications can be obtained on request to Dr. Aldridge.

later (Ernst and Barbour 1972). Each gravid female comes onto land, locates an appropriate nest-site, and excavates a flask-shaped cavity in (usually) sandy or loamy soil (Cagle 1937). She then deposits a clutch of 2–20 eggs in the subterranean chamber (Ernst and Barbour 1972). The eggs in most clutches are arranged into layers, with eggs at the bottom being only 6–10 cm from the surface of the ground and those at the top being even more superficial in their location (Cagle 1937; Cahn 1937; Ernst and Barbour 1972; Legler 1954). The female then scrapes dirt back into the neck of the cavity, camouflages the opening, and returns to water (Legler 1954), leaving the eggs to develop under physical conditions dictated largely by prevailing weather, by depth of the egg chamber, and by slope and aspect of the nest site (Packard and Packard 1988).

Baby painted turtles hatch from their eggs approximately two months after oviposition (Cagle et al. 1993; DePari 1988), but the neonates do not emerge immediately from their nest cavity. Instead, the hatchlings usually remain inside the shallow nest throughout the autumn and winter, and do not dig their way out of the chamber until the following spring (Breitenbach et al. 1984; Cagle 1954; DePari 1988; Hartweg 1946; Lindeman 1991; Mitchell 1988; Packard et al. 1989; Woolverton 1963). This "adaptive strategy" for overwintering apparently enables hatchlings to avoid exposure to predators at a time of year when days are becoming shorter, ambient temperatures are declining, and opportunities for growth are limited (Wilbur 1975). The strategy may have profound consequences, however, for neonates in populations toward the northern limit of the range of distribution.

Temperatures in nests are highly variable during winter at higher latitudes. Nests in protected sites that receive a deep, insulative layer of snow may not experience temperatures much below freezing at any time during winter (Breitenbach et al. 1984; Packard et al. 1989; Paukstis et al. 1989). In more exposed locations, however, lower temperatures may be sustained in nests for several weeks (DePari 1988), and minima between -5°C and -10°C may occur during the coldest part of winter (DePari 1988; Packard et al. 1989; St. Clair and Gregory 1990; Storey et al. 1988; Woolverton 1963). Hatchlings do not migrate downward into the soil to avoid these temperatures, but instead remain in the nest chamber where they necessarily encounter the cold (Breitenbach et al. 1984; DePari 1988; Storey et al. 1988). Nonetheless, many hatchlings survive such exposure and subsequently emerge from their nests when the ground thaws in the spring (DePari 1988; Packard et al. 1989; Storey et al. 1988; Woolverton 1963).

The remarkable ability of neonatal painted turtles to survive exposure to subzero temperatures has been widely attributed to a tolerance by the animals for freezing of water in the extracellular space (Zug 1993). According to this theory of "natural freeze tolerance," hatchlings begin to freeze at high subzero temperatures when liquid in the extracellular compartment reaches a limit of supercooling or when this solution is inoculated (or "seeded") by ice penetrating into the compartment from the frozen soil (Storey and Storey 1992). Freezing of extracellular fluids presumably is initiated when temperature is at or slightly below the equilibrium freezing point of -0.65°C (Packard and Packard 1995; Storey et al. 1991), so cells are not subjected to the osmotic shock that would occur if the extracellular fluids were supercooled more deeply before they began to freeze (Claussen et al. 1990). Moreover, small amounts of "cryoprotectants" (like glucose) may be released from the liver and distributed to peripheral tissues before the circulation is caused to shut down by ice forming in vascular channels (Churchill and Storey 1991; Storey et al. 1988). These cryoprotectants presumably protect cells from damage that would otherwise result from the cellular dehydration which accompanies freezing of water in the extracellular space (Carpenter and Crowe 1988).

Close examination of the theory reveals some shortcomings, however. For example, the theory rests, in part, on the belief that turtles are caused to freeze at high subzero temperatures by spontaneous (= homogeneous or heterogeneous) nucleation or by inoculation (Storey and Storey 1992). One line of evidence supporting this belief is the observation that hatchlings in some laboratory studies began to freeze at temperatures between -1°C and -4°C (Churchill and Storey 1992; Storey et al. 1988)—a result that has been taken to mean that the animals experienced spontaneous nucleation. However, the procedure for holding neonates prior to study apparently caused skin in the axillary and inguinal pockets of the turtles to be contaminated with damp sphagnum (Packard and Packard 1995). When the turtles later were exposed to subzero temperatures, water in the sphagnum must have frozen and the resultant ice probably caused the turtles themselves to freeze by inoculation (Packard and Packard 1995). Indeed, turtles that have been cleaned and dried prior to being exposed to subzero temperatures can easily be supercooled to -12°C without freezing (Packard and Packard 1993a, 1995). Thus, hatchlings actually are not at significant risk of freezing at high subzero temperatures as a result of spontaneous nucleation.

The companion belief, namely that hatchlings are highly susceptible to inoculation by ice in frozen soil, is based on studies of inoculative freezing in frogs, not painted turtles (Storey and Storey 1992). Recent experiments indicate that the extrapolation from frogs to painted turtles is unwarranted, because the integument of the head, neck, and limbs of hatchlings resists the transmission of ice into body compartments from the environment (Packard and Packard 1993b). Although the integument in the axillary and inguinal pouches apparently is less resistant than skin on the extremities to conducting ice into body fluids (Packard and Packard, 1993b, 1995), neonates tend to withdraw their head and limbs into the shell during hibernation. This behavior minimizes the probability that soil will come into contact with skin in the axillary and inguinal pouches and thereby enhances the basic mechanism for preventing inoculation. The mechanism is effective, because neonates in artificial nests in frozen soil commonly remain alive and unfrozen at temperatures as low as -10°C (Packard and Packard 1993a, 1993b). Thus, inoculative freezing is not a foregone conclusion for turtles that are in contact with ice in the frozen soil.

The theory of "natural freeze tolerance" is weakened also by uncertainties concerning the ability of hatchlings actually to withstand freezing. Whereas turtles appear to have survived freezing in some experiments (Churchill and Storey 1992; Storey et al. 1988), none has tolerated freezing in other investigations (Packard and Packard 1993a, 1993b, 1995). Moreover, results of experiments reporting that baby painted turtles are tolerant of freezing are not entirely concordant, nor are the results easily reconciled with data from the field. For example, turtles in one laboratory experiment are said to have survived freezing at -2.5°C for 11 days, but none of the animals in another experiment from the same laboratory was able to tolerate freezing at -2.5°C for as long as 6 days (Churchill and Storey 1992). Animals that were frozen at -4.0°C in both of these experiments were dead within 12 hr (Churchill and Storey 1992), and no animal has survived even brief freezing at lower temperatures (Storey et al. 1988). Hatchlings in the field nonetheless withstand exposure to temperatures below -2.5°C for several months (DePari 1988), and some turtles

tolerate at least brief exposure to extremes of -10° and -11°C (DePari 1988; Woolverton 1963).

When the discrepancies between survival by animals in the lab and by those in the field are considered together with the unsupported assumption that turtles necessarily begin to freeze at high subzero temperatures, questions arise concerning the general importance to hatchling painted turtles of a tolerance to freezing. Such a tolerance presumably could enable some hatchlings to survive brief exposure to relatively high subzero temperatures, but surviving a brief bout or two of freezing usually would not see the hatchlings safely through the winter. Relatively high subzero temperatures that would lead to brief freezing are likely to exist in northern parts of the range of distribution only when the soil is cooling during early winter and warming in early spring. Thus, tolerance to freezing would not be sufficient to enable turtles to survive the long periods of exposure to lower temperatures that commonly occur in mid-winter in nests in the field (DePari 1988; Packard et al. 1989; St. Clair and Gregory 1990; Storey et al. 1988; Woolverton 1963).

A more likely explanation for the remarkable ability of hatchling painted turtles to withstand exposure to cold is that they sustain a state of supercooling and thereby avoid freezing altogether. Substances that could initiate the formation of ice seem to be absent from body fluids of hatchlings, so turtles are not at appreciable risk of freezing spontaneously at temperatures above -12°C (Packard and Packard 1993a, 1995). Moreover, the integument of hatchlings resists the transmission of ice into body compartments from the environment, so turtles are not assured of freezing even when they make contact with ice in the frozen soil (Packard and Packard 1993b). Consequently, turtles may survive extended periods in frozen soil without freezing (Packard and Packard 1993a, 1993b, 1995).

According to this theory of "natural freeze resistance," some turtles experience inoculation after they have been in contact with ice in the soil for periods of hours, days, or weeks (Packard and Packard 1993b, 1995). The vapor pressure of supercooled body fluids in a turtle is higher than that of ice in the frozen soil, and the difference is greater at low subzero temperatures than at high subzero temperatures (Salt 1963). Every animal therefore loses water vapor continuously by diffusion across its integument, and the rate of diffusion is determined by the degree of supercooling. This vapor presumably condenses onto nearby crystals of ice in the frozen soil, thereby causing the crystals to grow slowly toward the source of the vapor (Salt 1963). In time, the crystals may penetrate the skin and inoculate the body fluids, and the resultant freezing of body fluids is fatal (Packard and Packard 1993a, 1993b, 1995). The probability of inoculation, and death, consequently is influenced by both the duration of exposure to ice in the soil and the low temperatures that are reached in the nest cavity.

Thus, turtles that survive exposure to cold while overwintering in nests in the field probably remain unfrozen, and they do so without the benefit of antifreezes (Packard and Packard 1995; Storey et al. 1991). Indeed, this adaptive strategy has only two requirements: (1) heterogeneous nucleators must not be present in the body fluids, and (2) the integument must resist the penetration of ice into body compartments from the environment (Dorsey 1948). It remains to be determined whether these properties are unique to painted turtles or whether the properties are of wide occurrence among neonatal emydids.

Clutch Sizes in a Community of Snakes from the Mountains of the Valley of México

In recent years, studies associated with the evolution of clutch size have been of central interest. Although it seems to be the oldest topic in life history, we still need more data on several species of reptiles to test the influence of female body size on clutch size. Several studies have indicated that clutch or brood size increases with maternal body size in reptiles (Congdon and Gibbons 1985; Fitch 1985; Ford and Seigel 1989; Moll 1979; Seigel and Fitch 1984; Seigel and Ford 1987; Vitt 1986). In spite of these studies on evolution of clutch size, the relationships among female body size, clutch size, and offspring size in reptiles are not clear (Brockelman 1975).

Since Fitch's (1970) study on lizard and snake reproduction, nothing has been published on reproduction in snake communities. Most of the reports on reproduction for Mexican snakes have been based on single specimens (see review by Fitch 1970). Here we present reproductive data for 24 adult females of six species of snakes collected between 1983 and 1987 in pine and pine-oak forest in Zoquiapan (19°41'30"N, 98°42'30"W), and Cahuacán (19°37'48"N, 99°24'54"W) in the state of México at an elevation of 3200 and 2600 m, respectively.

Clutch sizes of 24 females of *Conopsis biserialis, Pituophis deppei deppei, Storeria storerioides, Thamnophis eques eques, Thamnophis scalaris scaliger* (Colubridae), and *Crotalus triseriatus triseriatus* (Viperidae) were recorded. Snakes were captured in the field between early July and September. They were taken to the laboratory and 22 of 24 were autopsied within 4–8 h after capture. The eggs were removed from the females and preserved in 10% formalin. The number of eggs in each ovary was recorded to obtain the clutch size, and one each of *Storeria storerioides* and *Thamnophis e. eques* were maintained in captivity. The captive females gave birth in July (*S. storerioides*) and September (*T. e. eques*) 1986.

The following data were recorded: snout-vent length (SVL), body mass of the adult females, clutch size, and total clutch mass of the offspring. We correlated the clutch size with SVL because the latter is a less variable measure of body size than mass. We used analysis of variance (ANOVA) to determine if clutch size was related to body size.

Table 1 summarizes the reproductive characteristics of the six species. Clutch size was positively and significantly correlated with SVL ($r^2 = 0.9106$, $F_{1,20} = 97.141$, $P < 0.001$) (Fig. 1).

The captive *Storeria storerioides* (SVL = 325 mm, mass = 42.0 g) gave birth to 19 offspring [mean SVL = 107.2 ± 5.6 mm (100–115 mm), mean mass = 1.54 ± 0.18 g (1.2–1.9)]. The relative clutch mass (RCM) of the female was 0.698 g. The captive female of *Thamnophis e. eques* (SVL = 367 mm, mass = 45.0 g) gave birth to 15 offspring [mean SVL = 148.6 ± 10.6 mm (140–170), mean mass = 1.97 g ± 0.23 (1.7–2.5)]; RCM was 0.655 g.

All species, except *Pituophis d. deppei* are viviparous, a characteristic of many squamates occurring at high elevations. Until

Table 1. Mean, standard deviation, and range for reproductive traits of six temperate zone species of Mexican snakes.

Species	Female		Clutch size	Egg diameter
	SVL (mm)	Mass (g)		(mm)
Conopsis biserialis	196.0 ± 9.4 (183–205) (N = 4)	11.03 ± 3.3 (6.7–15.0) (N = 4)	4.5 ± 2.3 (2.0-8.0) (N = 4)	14.9 x 8.0 (13.0 x 7.0–17.0 x 9.0) (N = 4)
Storeria storerioides	258.2 ± 29.1 (230.0–312.0) (N = 5)	15.3 ± 7.5 (9.0–30.0) (N = 5)	5.4 ± 2.6 (3.0–10.0) (N = 5)	21.2 x 10.1 (20.0 x 9.0–23.0 x 12.0) (N = 5)
Pituophis d. deppei	762.5 ± 96.0 (650.0–900.0) (N = 4)	——	18.0 ± 2.9 (14.0–22.0) (N = 4)	——
Thamnophis e. eques	331.5 ± 40.3 (268.0–367.0) (N = 4)	28.6 ± 7.8 (17.9–39.0) (N = 4)	10.7 ± 2.9 (7.0–15.0) (N = 4)	
Thamnophis scalaris scaliger	630.0 ± 60.0 (570.0–690.0) (N = 2)	——	15.0 ± 1.0 (14.0–16.0) (N = 2)	
Crotalus t. triseriatus	471.7 ± 16.5 (450.0–490.0) (N = 3)	——	10.7 ± 3.4 (6.0–14.0) (N = 3)	

now, there have not been any data available on clutch sizes of snakes that inhabit temperate zones of México. Our data show a significant correlation between SVL and clutch size for the six species ($X^2 = 3.972$, $P < 0.05$). The results suggest that clutch size is a function of female size. All species showed an increase in clutch size with increased female body size.

Variation in body size and clutch size within and among species (Table 1) could be evidence that these species are responding to factors such as phylogenetic relationships and food availability in the environment (Ford and Seigel 1989; Seigel and Ford 1991, 1992). Variation in life history traits, such as female body size, clutch size, offspring size, and growth rate is caused by energy intake (Ballinger 1977; Stearns 1976). For the snakes that we examined, we do not have data on food intake, but the relationship between body size and clutch size could be a response to the factors indicated above.

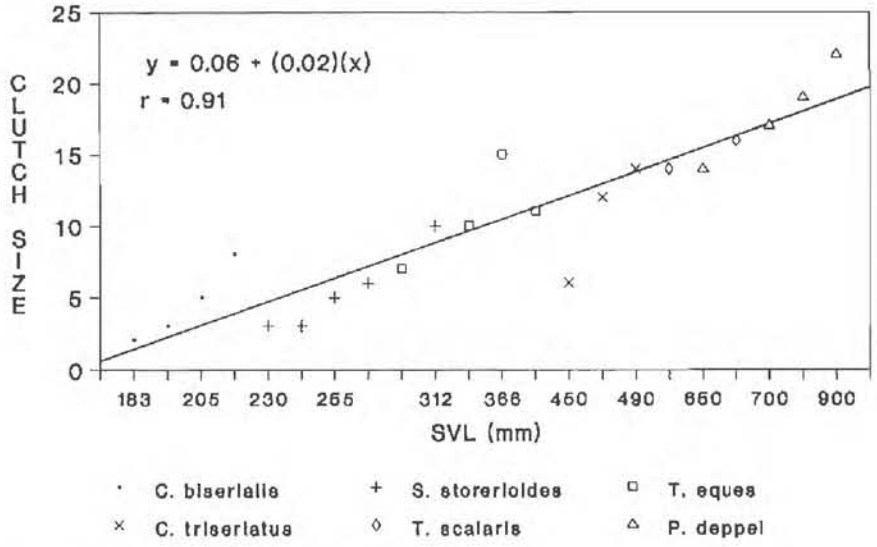

FIG. 1. Relationship of clutch size to snout-vent lengths.

Ford and Seigel (1989) found that life history traits, clutch size, and clutch mass changed in response to the food resource levels, and that changes in these characteristics could be a plastic response to the environment. However, for RCM they did not find any relationship with changes in resources availability. Our data set is too small to make comparisons as we only had two viviparous snakes that gave birth in captivity. The RCM of viviparous species reported by Seigel et al. (1986) was between 0.201 g in *Nerodia fasciata* and 0.426 g in *Tropidoclonion lineatum*, while in our two samples the RCM values were higher but SVL smaller. The SVL of *N. fasciata* was greater than that of *T. lineatum*, and the same characteristics in SVL were found for *Storeria storerioides* and *Thamnophis e. eques*, that is, the bigger snake had a lower RCM than the smaller snake. This could support the findings of Ford and Seigel (1989) that food intake and SVL are not related to RCM.

Acknowledgments.—We are grateful to R. W. Hansen, S. Corn, M. Benabib, E. Naranjo, B. Delfosse, and an anonymous reviewer for their helpful comments on the manuscript.

The Type Locality of the Frog *Acris crepitans*

The original type locality of *Acris crepitans* Baird (1854) has invariably been understood as the "northern states generally," inasmuch as Baird directly cited no other locality and gave the area indicated as the "habitat" for the species.

With that understanding, limited only by the parameters implied by the "northern states," two restrictions of the type locality have been published. The earliest (Smith and Taylor 1950:359) cited Albany, Albany Co., New York, as the restricted type locality, possibly because DeKay's work (1842), cited in the original description, was published there. That locality is, however, outside of the known range of the species, as pointed out by Duellman (1970:647), by about 80 km, and therefore that restriction is untenable. The northernmost precise locality of record in New York is "Third Binnewater Lake, 5 km SW Kingston, Ulster Co." (Benton and Smiley 1961). Although the species no longer exists there, one of us (ARB) has found it at several other sites in the immediate vicinity.

Unaware of the Smith/Taylor restriction, Schmidt (1953:68) restricted the type locality to the "Potomac River at Harper's Ferry, West Virginia," on unknown grounds. That restriction is here refuted, not because it is outside of either the known range of the species or the "northern states" (which might be construed as any Union state, which West Virginia was, or any north of the Mason-Dixon line, which West Virginia was not), but because the original description does, in fact, provide a more restricted locality than has been assumed in acceptance of the "northern states" as the original type locality.

Baird (1854) not only described the species, briefly, but cited as a synonym "*Hylodes gryllus* LeConte" of DeKay's great classic on the zoology of New York (1842:70, pl. 22, fig. 61). That reference is therefore a part of the type material (hypodigm), and it does clearly provide a more restricted locality for the species, namely New York. This we regard as the original type locality, inasmuch as Baird actually did not specify a type locality as such—only the general range, under the rubric of "habitat.".

Unfortunately no more precise locality than "New York" is cited for the species in DeKay's work, but it is reasonable to suppose that DeKay observed the frog near his home, indicated in the preface of the book as "The Locusts, Queen's County."

According to The National Cyclopaedia of American Biography, in the 1830's "the state of New York was publishing valuable works ... and Dr. DeKay was selected to contribute a book on the zoology of the state, a work of great difficulty, owing to the lack of printed material.... The result of his work was embodied in five quarto volumes.... In order to work at his zoology, he left the city for "The Locusts," a country place at Oyster Bay, Long Island, where he resided until his death" 21 November 1851. The eastern part of the original Queen's Co. was separated in 1899 as Nassau Co., where Oyster Bay is now registered.

There are several early collections of *Acris* from Queen's, Nassau, and Suffolk counties, so it is apparently safe to assume that the frog occurred in the vicinity of DeKay's home and that he was familar with it. Although at one time the species undoubtedly ranged throughout the island, no records after the 1930's exist, and the species may well no longer occur there.

Nevertheless, since the species did once occur in the vicinity of DeKay's home near Oyster Bay, where most of the Zoology of New York was written, we regard the present restriction of the type locality of *Acris crepitans* to "The Locusts, near Oyster Bay, Nassau Co., Long Island, New York" as appropriate and soundly conformant with present knowledge.

Evidence of Possible Sperm Storage in the Caiman, *Paleosuchus palpebrosus*

Sperm storage has been reported in a number of chelonians and squamates but it has not been reported in crocodilians (Ferguson 1985). In squamates, sperm storage is made possible by structures located in the oviducts and in some species fertile eggs can be produced months or even years after copulation (Goin et al. 1978). Some male snakes store sperm over winter in the ductus deferens and are then used during mating the following spring (Seigel and Ford 1987). Some chelonians can also store sperm, females producing viable eggs for several years after last mating (Goin et al. 1978). Hatten and Gist (1975) found sperm stored in the albumen secreting tubules in the box turtle, *Terrapene carolina*. Gist and Jones (1987) later reported stored sperm in these structures in nine species of chelonians.

On 25 February 1981, the National Zoological Park received one male and three female dwarf caiman, *Paleosuchus palpebrosus*, from Surinam. A fourth female was added to the group on 5 August 1984. Sex was determined using the method described by Brazaitis (1969). This group was moved into a livestock watering tank on 12 September 1990 and maintained there until 6 March 1991 when three of the females were removed. These three females have since been maintained together without contact with

any other individuals. On 7 July 1992, 488 days after the last contact with a male, 16 eggs were found submerged in the tank. Mean egg weight was 64.8 g (range 59.2–68.0 g), mean width was 40.3 mm (range 38.3–41.4 mm) and mean length was 66.9 mm (range 63.1–70.1 mm). All eggs were normal in appearance and were incubated at approximately 28°C in an environmental chamber. By 10 July, six eggs had begun to band, an indication of fertility (Ferguson 1985). Mean band width measured at the top of each egg was 20.2 mm (range 13.9–28.9 mm). By 16 July, band width had increased to a mean 31.7 mm (range 27.7–37.0 mm) indicating embryonic development. A seventh egg began to band on 18 July. As band growth seemed arrested by the beginning of September, the seven eggs were dissected by NZP pathologists to determine development. One egg contained a live, well-developed embryo. The remaining six eggs had decayed to the point that possible embryonic tissue could be seen only in two, possible blood spots in another two, and in the remaining two eggs nothing indicating fertility could be discerned.

On 24 January 1993 two of the three females were measured. Their snout-vent lengths were 59.6 cm and 56.3 cm. The third female is of very similar size. At this time, the sex of the three females was rechecked (Brazaitis 1969).

In crocodilians, the interval between insemination and egg-laying reportedly varies between species (Ferguson 1985). The longest interval, five months, was reported by Pooley and Gans (1976) for the Nile crocodile, *Crocodylus niloticus*. This was determined through field observations but in such cases it may be difficult to determine when copulation attempts are successful or if the male is producing viable sperm. In captivity at the National Zoological Park, Cuban crocodiles, *Crocodylus rhombifer*, begin to court and attempt copulation in December and continue for several months before eggs are laid the following April or May (pers. observ.). Even though pool water is relatively clear and the crocodiles are close to the observer, it is still difficult to determine when copulation attempts are successful. Ferguson (1985) suggested detailed autopsies to verify the seemingly variable intervals between insemination and egg-laying in different species. The interval measured here for *P. palpebrosus* is the longest reported in a crocodilian. No attempt to locate sperm storage structures in this species has been published; however, they have not been found in either the American alligator, *Alligator mississippiensis* or *C. niloticus* (Ferguson 1985). Detailed descriptions of the adult crocodilian oviduct are not available, though it reportedly is generally similar to that of chelonians (Gist and Jones 1987). However, because sperm storage structures have not been reported in crocodilians does not mean they do not exist. Long term sperm storage in chelonians was reported before the sperm storage structures, the tubular albumen-secreting glands in the oviduct, were discovered (Hatten and Gist 1975).

A decrease in fertility was noted in this clutch of *P. palpebrosus* eggs compared to other clutches laid at NZP by females with continuous access to a male. Similarly, decreases in fertility have been shown to occur in egg clutches laid by diamondback terrapins, *Malaclemys terrapin*, as the time interval from last mating increases (Goin et al. 1978).

Sperm storage may be an advantage for a crocodilian species which reportedly occurs in low densities in the wild (Ross and Magnusson 1989). Such a capability would allow reproduction by females that do not have regular access to males.

Acknowledgments.—I thank Geoffery Birchard and Dale L. Marcellini for their helpful critiques of the manuscript.

Distributional Notes for the Night Lizard *Lepidophyma gaigeae* (Xantusiidae)

Gaige's tropical night lizard, *Lepidophyma gaigeae*, is a relatively small flat-bodied member of the family Xantusiidae, variously placed in the subfamily Xantusiinae (Savage 1959) or Lepidophyminae (Crother et al. 1986; Smith 1987). Since its original description by Mosauer (1936), the scattered published records report this night lizard as occurring in rock fissures and between loose rocks in limestone areas. It occurs chiefly in pine-oak forests, as well as the walnut belt of the Sierra Madre Oriental in northwestern Hidalgo and northeastern Querétaro, México, at elevations of 1515–2200 m (Bezy 1984, 1988, 1989; Bezy and Camarillo 1992; Dixon et al. 1972; Smith 1973; Smith and Taylor 1950). Xantusiid lizards have been described as habitat specialists (Bezy 1989), and the ranges of the majority of species are fragmented, characteristic of primitive, relictual groups (Bezy 1972).

In early August 1991, the author and two colleagues, Carlos Camacho (CCA) and Dionisio Saucedo (DSR) found two *L. gaigeae* (AGA0767, SVL = 42.5 mm, sub-adult; CCA01 1, SVL = 55.1 mm, adult) about 2 km SSW of the small village of Verdosas (10 airline km north of Zimapán, and 18 km ESE of Durango, Hidalgo). The habitat at this locality is pine-oak forest, and both lizards were found under loose rocks on a rocky slope at elevations of 2170 and 2520 m respectively (Figs. 1A, B). The following reptiles, associated with the same habitat at this locality, were also collected: *Sceloporus grammicus, S. jarrovi immucronatus, S. torquatus melanogaster, S. parvus scutulatus, Gerrhonotus liocephalus taylori, Leptophis mexicanus*, and *Crotalus triseriatus aquilus*.

In addition, during field trips to eastern Querétaro and western Hidalgo (near the border between these states) the author collected two specimens of *L. gaigeae* in October 1989 and April 1990. The

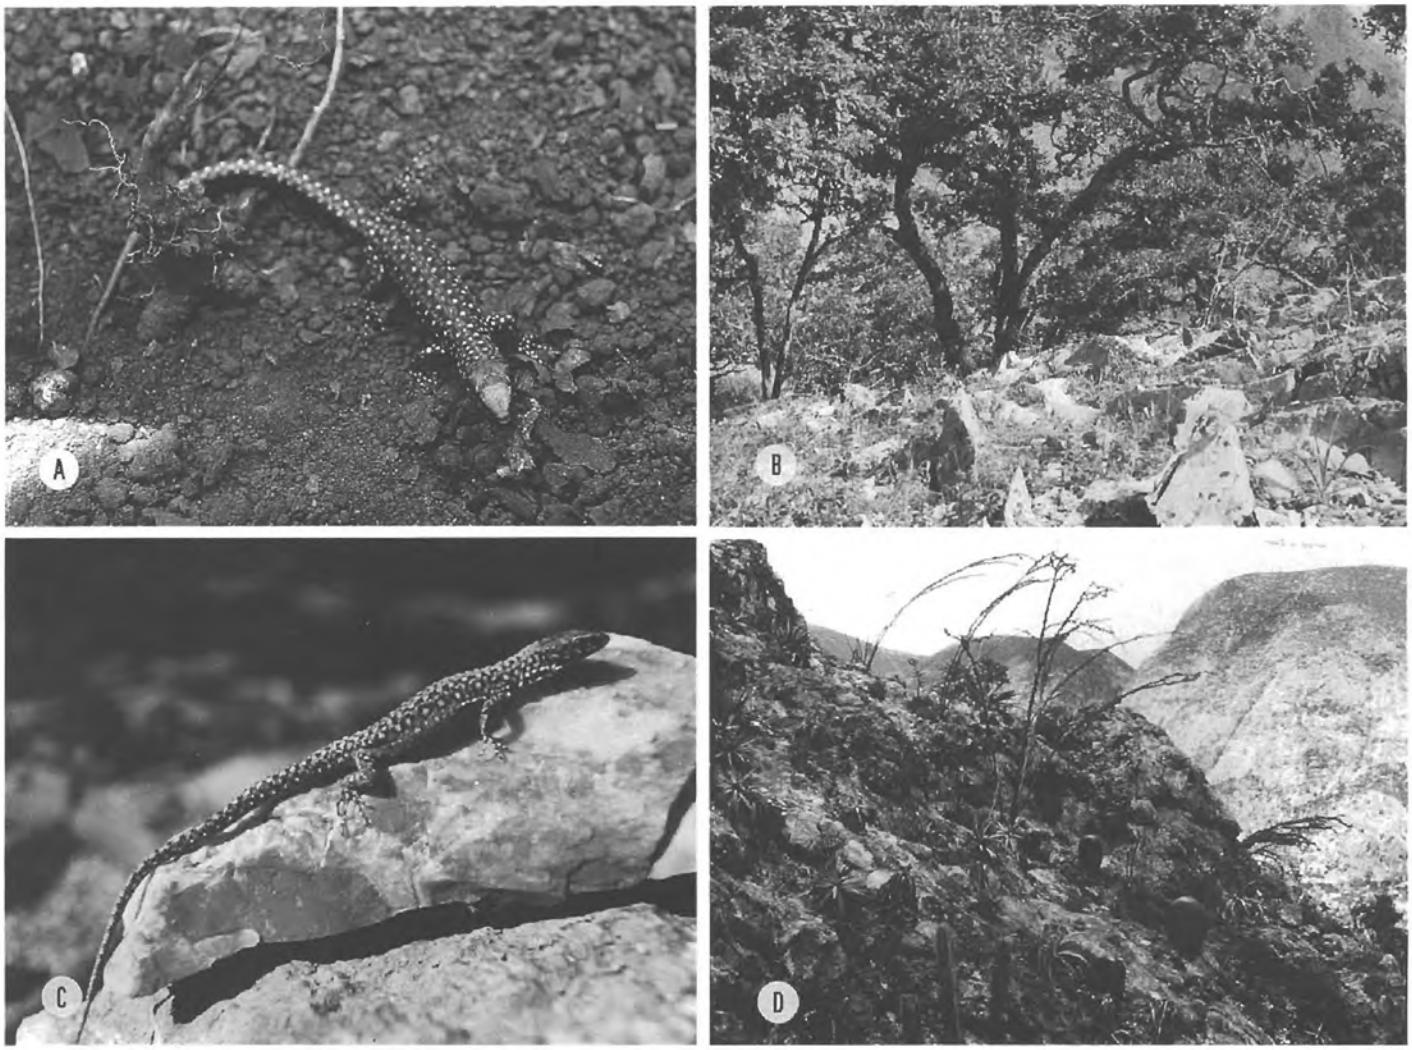

FIG. 1. Living individuals of *Lepidophyma gaigeae* and their habitats in Hidalgo and Querétaro. A. Adult specimen CCA011 from Verdosas, Hidalgo. B. Pine-oak forest at Verdosas, typical habitat of *L. gaigeae*. C. Adult specimen AGA0644 from Cerro Prieto, Querétaro. D. Xerophytic vegetation of Cerro La Cruz, near El Arenal, Hidalgo, an unusual habitat for *L. gaigeae*. The Cañon del Infiernillo and Cerro Prieto are visible in the background.

specimens were taken at two localities near the confluence of the Río Tula and Río San Juan, which then become the Río Moctezuma, which in turn flows through Cañon del Infiernillo (Fig. 2). An adult specimen (Fig. 1C; AGA0644, SVL = 49.1 mm) was found in a crevice on a rocky slope of Cerro Prieto, north of Rancho Nuevo, ca. 30 km ESE of Cadereyta de Montes, Querétaro, at an elevation of 1560 m. A juvenile specimen (AGA0667, SVL = 37.0 mm) was found in a similar area on Cerro Prieto, but close to the western edge of the Cañon del Infiernillo at 1532 m. A third specimen (AGA0762, SVL = 51.6 mm, adult) was collected in June 1991 under rocks in a small cave in the mountains, 1 km south of El Arenal, Hidalgo, not far from the eastern margin of the Río Tula, at an elevation of 1520 m (Fig. 2). At least three other specimens were observed in the cave or at its entrance.

All specimens (except AGA0667) are still alive in the Laboratorio de Herpetología of the Escuela Nacional de Estudios Profesionales Iztacala (ENEPI), UNAM, in Tlalnepantla, State of México.

In contrast to the Verdosas area, the above-mentioned localities support xerophytic vegetation—the crassicaule desert bush association—whose main elements are *Stenocereus dumortieri, Myrtyllocactus geometrizans, Astrophytum ornatum, Cylindropuntia* sp., *Opuntia* sp., *Mammillaria compressa, M. elongata, Echinocactus platyacanthus, E. grusonii, Prosopis laevigata, Celtis pallida, Fouqueria splendens*, and *Jatropha dioica* (CFE-PHZ 1989; Rzedowski 1981) (Fig. 1D). Other reptiles found at these localities are characteristic of xerophytic habitats: *Sceloporus variabilis variabilis, S. parvus scutulatus, S. spinosus spinosus, Cnemidophorus gularis scalaris, Trimorphodon tau tau*, and *Pituophis deppei jani*.

Our collection of *Lepidophyma gaigeae* from xerophytic habitats parallels the situation in northern Querétaro, where the species occurs primarily in pine-oak woodland, but is rarely found in thorn scrub of the Jalpan Valley at 600 m (Dixon et al. 1972). Our records extend the range about 42 airline km SSW of the southernmost distributional record previously published: 27 km S of Jacala, near Durango, Hidalgo (see Fig. 2; Bezy 1984; Dixon et al. 1972).

As in populations of *L. gaigeae* occurring between El Lobo and Jalpan, Querétaro (Dixon et al. 1972) and near Durango in Hidalgo (Mosauer 1936; Smith 1973), the specimens reported herein belong to populations separated from each other by vegetational differences, topography, and the Río Moctezuma. These observations suggest that either: 1) the distribution of *L. gaigeae* is broader

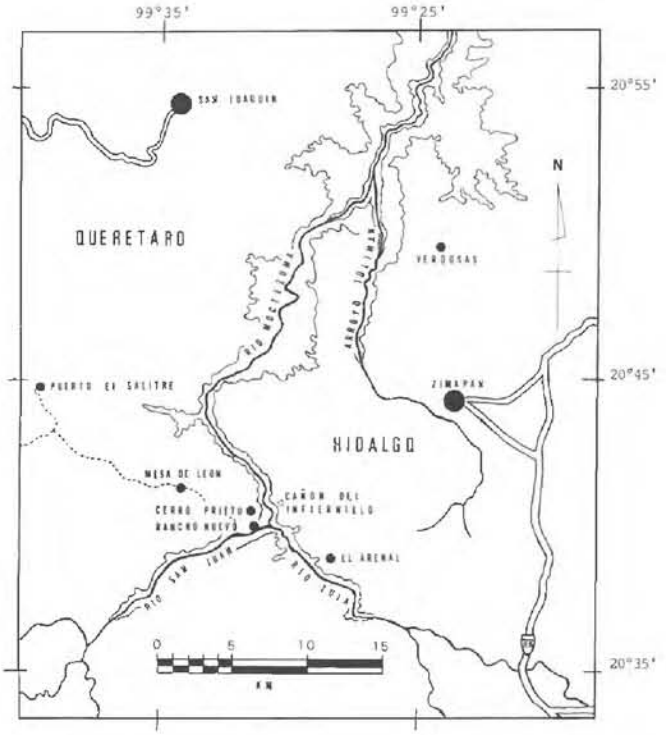

FIG. 2. Collection sites of *Lepidophyma gaigeae* in eastern Querétaro and western Hidalgo, México (refer to text). Additional points of reference are included.

than presently documented, and perhaps is nearly continuous between known populations, but obscured by low densities and secretive habits; or 2) these are relictual populations and reflect the previous range of the species. Clearly, additional field work is needed to more accurately understand the distribution of *L. gaigeae*.

Acknowledgments.—I thank the following persons for their valuable criticisms and suggestions on the first drafts of the manuscript: Enrique Godfnez C. and Amaya Gonzalez R. (Laboratorio de Herpetología, ENEPI, UNAM), Fernando Mendoza Q. and Oscar Flores V. (Museo de Zoología, Facultad de Ciencias, UNAM), Oscar Sánchez H. (Instituto de Biología, UNAM), and Richard R. Montanucci (Clemson University). Appreciation is extended to Dionisio Saucedo R. and Carlos Camacho A. for their field assistance.

POINTS OF VIEW

Scalation: Terminological Acceptance Long Overdue

Herpetologists writing in the English language have essentially universally applied the term "scale" to the "thin, flat, overlapping, rigid, horny plates forming the outer protective covering of the body in many ... reptiles...," as defined in Webster's New World Dictionary, revised 1980. Essentially the same definition is given in the other great dictionaries of the English language (e.g., the Oxford English Dictionary, 1989; the American Heritage Dictionary, 1992; the Random House English Dictionary, 1987; Webster's Third New International Dictionary of the English Language, 1976), as well as the many, far more frequently used abridged dictionaries widely distributed in schools and homes throughout the U.S.A. and other countries. As noted in virtually all such references, "scale" is also applied to the similar structures of fishes, on the tail of some mammals, and on the legs of most birds. Analogous structures on the wings of most lepidopterans also are termed scales, and so are several other structures of both organic and inorganic occurrence. The epidermal reptilian, avian, and mammalian structures are now accepted as homologous, the others not.

A few other names have been applied to reptilian scales, such as squamae, scutes, plates, shields, laminae, and scutella (Peters 1964:310), but they are seldom used except in a few special contexts (Dundee 1989:63). "Scute" in herpetology refers usually to large scales, as do "lamina," "shield," or "plate" (Peters 1964:315). On the other hand, "scutella" are regarded commonly as small

scales, as stated by both Peters (1964:315) and general English dictionaries (e.g., Webster's New World Dictionary, revised 1980, p. 1282). Although "squama" is a term commonly noted in dictionaries (but not, per se, in Peters' book), it is almost never used in herpetology, perhaps as too stilted, pompous, or affected, especially with the term "scale" so widely accepted and commonly used. Dundee (1989) suggested that herpetologists might well confine themselves "wholly to scute or scale for all epidermal derivatives."

Curiously, however, with rare exception dictionaries include only those nouns, meaning the state or arrangement of scales, that are derived from the least used alternatives for "scale." Of such nouns, the most commonly adopted in herpetological literature is "scutellation," and this is the term that most meticulous editors have insisted be used instead of "scalation." "Pholidosis" is also to be found in dictionaries, derived from the Greek word "pholidos," but that word, or a derivative thereof, has apparently never found its way into English herpetological usage in lieu of "scale." "Squamation" also is commonly cited in dictionaries (but, strangely, not in Peters) and Peters (1964:315) lists "scutation," but both are objectionable on the basis of derivation from words seldom used for the structures involved. "Lepidosis" appears in several of the Webster dictionaries, in application to scale arrangement, but is also derived from a word (lepis) always used only in compound words.

"Scalation" is the inclusive to be preferred, because of its derivation from the overwhelmingly preferred term "scale." It even crept into Peters' dictionary (1964:261), where he defined "pholidosis" succinctly and simply as "scalation," although the latter term did not appear otherwise in his book, perhaps in deference to the absence of the term, even though "natural," in all of the most frequently used English dictionaries.

Two exceptions, and only two, to the general absence of "scalation" in English dictionaries, have been found. The 1976 edition of Webster's Third New International Dictionary entered the word and defined it simply as "lepidosis 2," in turn defined as "the arrangement and character of the scales or shields of an animal" (otherwise as "a scaly skin disease (as ichthyosis)"). The 1987 edition of the Random House Dictionary of the English Language likewise has an entry for "scalation," defined as "1. an arrangement of scales, as on a fish. 2. ichthyosis."

The origin of the term "scalation" is uncertain. It was frequently used by Taylor, appearing in his first publication in 1915 (e.g., p. 103, last line). Even earlier, in 1911–1912, he used the term in a dissertation written in partial fulfillment of the requirements for a Master's degree; the manuscript was published posthumously (Rundquist 1993). The word "scalation" appears at least on p. 12 of the published dissertation. Taylor continued to use that term until about 1936, when he switched to "squamation."

Not surprisingly, Smith (e.g., 1936), as a student of Taylor's, also freely used the term "scalation," until persuaded that it was "officially" (i.e., in known dictionaries) non-existent.

Actually, no "official" lexicon in English exists to which usage must conform. If a word is used in print, it exists, and its usage, or awareness of its usage, is the only qualification necessary for inclusion in dictionaries or any of the several registers of new words, of which that by Algeo and Algeo (1991) is the most informative and delightful by virtue of its introduction—a virtual primer in neologistics. According to those authors, a word is "new" if it does not appear in dictionaries at the time of its consideration, and under that definition, "scalation" can no longer be considered "new," because of its known usage of over at least 80 years, and its inclusion in at least two dictionaries in the last two decades. The Algeos go on to observe that some new words, termed "nonce" words, are "coined for a particular use and unlikely to become a permanent part of the vocabulary," and on those grounds are sometimes rejected for new-word registers. Certainly "scalation" does not fall in the nonce category. Indeed, its role is of long-standing and of considerable potential magnitude.

Obviously lexicographers up to the present time have given inadequate weight to the existence of "scalation" in the herpetological sense (certainly extendable to other vertebrates in which homologous scales occur, and even to fishes, whose scales are not homologous with the tetrapod ones, but are so closely analogous that the same derivative of "scalation" does not offend propriety), or to the much greater rationale for its existence and usage than for any of the commonly entered alternatives. On the basis of that rationale, and of the word's respectable history of usage, we urge that herpetologists and others no longer avoid usage of the term, where appropriate, in their attempts to conform with assumed dictionary authority that in fact has no "official" standing and is no longer universal. Lexicographers should make amends for past omissions by inclusion of "scalation," if need be at the expense of some of the usually entered synonyms that are seldom used and/or are less appropriate, in future editions of abridged as well as unabridged lexicons.

Acknowledgment.—Vital counsel provided by Harold A. Dundee is most gratefully acknowledged.
